d. Using the electronic medical record to review trends of the patient's blood glucose levels

. The nursing assessment of a patient with a diagnosis of anorexia nervosa reveals the patient consumes a vegan diet of 700 calories daily and has lost 30 lb in 4 months. The nurse's recommendation to meet with a nutritionist is the outcome of which process?
a. Clinical judgment
b. Nursing process
c. Clinical reasoning
d. Critical thinking

. A nurse working in a long-term care facility reviews the electronic health records of patients who have fallen in the last month to determine if there is a common risk factor. Which QSEN competency is the nurse demonstrating?
a. Patient-centered care
b. Evidence-based practice
c. Teamwork and collaboration
d. Informatics

. A new graduate nurse phones the surgeon to report their patient is having severe incisional pain. The surgeon asks about vital signs and appearance of the wound, causing the nurse to return to the bedside for additional assessments. Upon reflection with the preceptor, which characteristic of the nursing process should the nurse have remembered?
a. Centric
b. Dynamic
c. Interpersonal
d. Systematic

. The nurse is formulating a care plan for a patient in a long-term care facility who has lost 12 lb in the last 2 months. To arrive at a patient-centered nursing judgment, what will the nurse do first?
a. Ensure the patient is receiving foods they like, including favorites.
b. Make sure the patient's dentures are clean and inserted at mealtimes.
c. Assess the patient's food intake and hydration over the last 1 to 3 days.
d. Request that the nursing assistant feed the client at mealtime.

. When implementing a thoughtful, patient-centered care plan, which action does the nurse prioritize?
a. The patient's loved ones are considered part of the team.
b. A caring relationship with mutual trust is established.
c. Measures for safety are visibly incorporated.
d. Transparent communication is observed.

. An oncology nurse is analyzing a patient's strengths and finds the patient is well educated, learns quickly, and is resilient. In which phase of the nursing process will the nurse use this information?
a. Diagnosing
b. Evaluating
c. Planning
d. Implementing

ANSWERS WITH RATIONALES

. **a, b, e**. The nursing process ensures that nurses are person centered rather than task centered. Attending to cultural preferences and needs and listening to a patient's concerns are patient-centered actions. Documentation and communication with other members of the health care team are not specifically patient centered.

- **c.** Reassessing the patient allows the nurse and patient to clarify the patient's goal(s) and develop interventions to best meet them. Once the problem is addressed, it is important for the nurse to judge the adequacy of the knowledge, identify potential problems, use helpful resources, and critique the decision.
- **b**. Interpersonal. All other options are characteristics of the nursing process but focus on the patient best illustrates the interpersonal dimension of the nursing process.
- **a**. When intuition is used alone, increased risks and fewer benefits may occur. Beginning nurses must use nursing knowledge and scientific problem solving as the basis of care; intuitive problem solving comes with years of practice and observation. If the beginning nurse has an intuition about a patient, that information should be discussed with the faculty member, preceptor, or supervisor. There is a place for intuitive reasoning in nursing, but it will augment, not replace logical, scientific reasoning. Critical thinking is contextual and changes depending on the circumstances, not on personal preference.
- **a, c.** Using critical thinking to teach a patient about a disease process and management and monitoring for side effects of medications are cognitive competencies. Performing an injection correctly is a technical skill; witnessing/signing an informed consent form is a legal/ethical action, and comforting a patient is an interpersonal skill.
- **b, c, e.** Critical thinking applied to clinical reasoning and clinical judgment is guided by standards, policies and procedures, and ethics. When applying principles of nursing process, problem solving, and the scientific method, clinical reasoning identifies the key problems, issues, and risks. This is driven by patient, family, and community needs as well as nurses' needs to give competent, efficient care. It also calls for strategies that make the most of human potential and compensate for problems created by human nature. It is constantly reevaluating, self-correcting, and striving to improve the quality and safety of health care systems (Alfaro-LeFevre, 2014).
- **a**. Patient-centered care commits to developing caring relationships based on mutual trust to communicate and deliver care based on patient preferences and values. Evidence-based practice integrates the best current evidence for safe practice with clinical expertise. Teamwork and collaboration shares patient information or opportunities for learning with others. Informatics manages patient information, mitigates error, and supports decision making using the electronic medical record and other databases.
- **a.** Clinical judgment is the outcome of critical thinking and clinical reasoning, using the nursing process as a framework. Clinical reasoning refers to ways of thinking about patient care issues including weighing and validating options (determining, preventing, and managing patient problems). Critical thinking includes reasoning both outside and inside of the clinical setting.
- **d**. Informatics uses information and technology to communicate, manage knowledge, mitigate error, and support decision making. Thoughtful, patient-centered care emphasizes recognition of the patient or designee as the source of control and full partner in compassionate and coordinated care, based on respect for patients' preferences, values, and needs. Evidence-based practice integrates the best current evidence with clinical expertise and patient and family preferences and values to deliver optimal health care. Teamwork and collaboration refer to effective functioning within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.
- **d**. The nursing process is systematic, iterative, and overlapping. By reporting an isolated symptom, the nurse has overlooked the benefit of systematic and inclusive assessment. While the nursing process is presented as an orderly progression of phases, there is a dynamic interaction and flow of phases into one another.
- **c.** The nurse uses the nursing process to arrive at a clinical judgment. After analyzing the assessment data, the nurse determines, through clinical reasoning, whether the related factors in the patient's weight loss, such as dislike of menu options, lack of dentition, or inability to perform activities of daily living such as feeding, should be the focus of interventions.
- **c.** Although developing a thoughtful, patient-centered approach is focused on caring and mutual trust, the nurse uses the nursing process and Maslow's hierarchy of needs to prioritize care. Safety is a higher-level need than love and belonging, and therefore the priority.
- **a.** Assessing for strengths and weaknesses is the first step of the nursing process, which has been completed. Next, the nurse clusters cues and develops diagnoses that give rise to interventions. Evaluating the plan is followed by completing or modifying the plan.

Clinical Judgment

Ashley Dotski

Ashley is a student nurse with no clinical experience and no legacy of nursing in her family or circle of friends. She wants to be a nurse and is interested in pediatrics but is open to exploring different possibilities in nursing. Ashley is focused on developing her critical thinking skills before she begins her first clinical rotation.

Daniel Ramirez

Daniel, a student nurse, has divulged to an academic advisor that he suffers from some test anxiety and is nervous about the licensure test. He states, “I tend to do worse on the first exam in a course because I need to get a feel for the teaching and the teacher’s testing style before I figure out how to study.”

Kallie McDonald

Kallie is a paramedic returning to school to be a nurse. They are trying to not divulge that they have

some health care background for fear they will be held to a higher standard than the other student nurses.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe the concepts of critical thinking, clinical reasoning, and clinical judgment.
. Compare and contrast models, frameworks, and theories related to the development of clinical judgment.
. Explain how competency models are used in nursing education.
. Describe the cognitive theories that underpin clinical decision making.
. Identify your plan to integrate previous and newly gained knowledge into your nursing practice to drive the development of clinical judgment.

Nursing Concepts

Advocacy
Clinical decision making/clinical judgment
Collaboration/teamwork and collaboration
Ethics
Professional identity
Managing care

Key Terms

clinical judgment
clinical reasoning
cognitive load
competency
critical thinking
situational awareness (SA)

Your exploration and development of clinical judgment will continue well past your formal undergraduate education. Clinical judgment, informed by experience, develops over the course of your professional nursing career. The brief descriptions of educational principles presented will help you appreciate foundational concepts and theories as they relate to your personal and professional development. Education is based on fairly predictable pedagogical and andragogical principles. We will explore some of these principles and theoretical models as we provide you context for the development of clinical judgment and highlight concrete steps you can take to cultivate an adaptive decision-making process. We will also spend time highlighting specific tools and resources used throughout this text to provide exemplars of how to engage in this developmental work. This chapter is designed to foster your clinical judgment by including you in the process of education through an exploration of the common threads that guide nurse educators who foster, facilitate, and guide you through your exploration of the profession of nursing.

See the Reflective Practice box on the next page and consider your role in maximizing your personal professional development and the professional development of your peers.

CONCEPTS RELATED TO CLINICAL JUDGMENT

Critical thinking, clinical reasoning, and clinical judgment occur in the quiet moments. For example, framing your approach to a patient using their identified pronouns requires a measure of clinical judgment. Identifying and then using an algorithm or protocol based on your clinical findings requires clinical judgment. Reviewing the evidence and contributing to the development or revision of that algorithm or protocol requires clinical judgment. We use clinical judgment to determine whether we must immediately call the provider, or if there are additional assessments that we should perform to formulate a recommendation. Deciding whether something you know about the patient, such as their HIV+ status, is germane to the SBAR report you give to the oncoming nurse requires clinical judgment. To frame clinical judgment and ensure we are all using the same working definitions, we should review some key terms. Although there are subtle differences in how nurse educators define these terms, we are going to explore the core tenets of critical

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

thinking, clinical reasoning, and clinical judgment.

Critical Thinking

Alfaro-LeFevre (2020a) posits that we should replace the word *critical* in *critical thinking* with *important* because the thinking that is done with respect to nursing care is important! The term critical thinking applies to thinking that occurs within the clinical and education settings but also applies in everyday life. What is important to remember is that critical thinking is a skill that can be developed—it often requires intentional focus and work, but the ability to think, reason, consider options, and problem solve can be learned. Snyder's (1993) definition of critical thinking references problem solving that is "both creative/intuitive and logical/analytic" (p. 207). Alfaro-LeFevre's (2020a) definition describes critical thinking as "knowing how to focus your thinking to get the results you need (includes applying logic, intuition, standards, and evidence-based practice)" (p. 8). Take a moment and put the term critical thinking into your own words. When you think about critical thinking, do you include elements of an orderly process that is reasonable, possible, and logical?

Consider this definition of **critical thinking** from Scriven and Paul (1987): "Critical thinking is the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by, observation, experience, reflection, reasoning, or communication, as a guide to belief and action" (p. 1). Other thought leaders have recognized critical thinking as a *concept* that does not have one universally accepted definition. Ennis (2016) offers an abbreviated, parallel definition: "reasonable reflective thinking focused on deciding what to believe or do" (p. 166). Student nurses often use critical thinking with test processing, when navigating new systems such as an electronic health record (EHR) or learning management systems (LMS), when learning in xteams, and when balancing daily activities with the pressures of school. As student nurses, not being provided *one* definition can be challenging, but sifting through the varied perspectives and formulating your own understanding and application of the concept of critical thinking to nursing practice requires … critical thinking!

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

I'm in my second adult medical-surgical clinical rotation this semester and am finally able to apply some of the skills I learned as a paramedic. Simulations are my favorite part of the course because we get to actually do everything. The team-based simulations are used to reinforce our learning and are not graded. I've found that my team of three student nurses tends to move quickly through every simulation and does most things correctly because I provide guidance and instruction throughout the entire scenario. During the debriefing yesterday, one of my peers pretty much called me bossy and asked me to "stop telling tell them what to do all the time." The other student nodded in agreement, and the faculty facilitating the debrief chastised me for jumping in and "not giving them a chance to think and prioritize for themselves."

Thinking Outside the Box: Possible Courses of Action

- I could nod in agreement and admit that I was bossy.
- I could explain my background and counter that I should not have to slow down to match their (too slow) speed.
- I could refrain from saying anything at all and talk to my two peers after the debriefing.

Evaluating a Good Outcome: How Do I Define Success?

- The simulated patient benefited from my actions—there was timely, correct intervention for this health problem.
- My peers and I all need to apply the information we've learned in class in specific situations, using the appropriate resources.
- Presentation matters, so perhaps my tone and assumption of the dominant role is something I could reconsider.
- If I am doing the right thing at the right time, my peers should benefit from watching me even if their preference is to make their own decisions and do it themselves.
- In this situation, I need to separate my personal feelings from my professional interactions.

Personal Learning: Here's to the Future!

I opted to explain my background as a paramedic and provide evidence-based rationale for my decision making in the simulation. My faculty facilitator did a really good job in separating the simulation actions from my professionalism and intraprofessional collaboration abilities. As we walked through the simulation

itself and reviewed our thinking and decisions at various points, I realized that I had missed a few things that would have slightly altered the order of our actions. It was interesting because one of my peers interjected that he didn't feel heard by the team during the simulation, and he had tried to mention the change in respirations twice. I learned that my team had valuable insight and that I (and the simulated patient) would have benefited from more intentionally including my peers in the process. We each approached the situation a little differently and had access to different information at various points, which means collaboration was actually necessary. During the debrief, the faculty facilitator guided us to talking about team process. It was clear I was not the appointed formal leader and that leadership does not always mean being the loudest or the first person to speak. I also listened to their words more closely and realized they had not used the word *bossy* at all; in fact, they were careful to talk about the situation objectively because they like and respect me. I probably need to work on my emotional intelligence and make time to focus on building relationships with my peers. I met with the faculty facilitator after the group debrief to gain more insight into the perceptions of others and discuss specific goals.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? Can you think of other ways to respond or approach the situation? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety when caring for simulated patients in a team-based learning model?

Patient-Centered Care: How could missing key data points change the course of action? Did the patent feel confident in all members of your team? Did the patient view you as in charge or as bossy? How do team dynamics impact on patient confidence, rapport, satisfaction, and outcomes?

Teamwork and Collaboration/Quality Improvement: What is emotional intelligence? How does self-reflection foster development of interpersonal, intraprofessional, and interprofessional communication skills? What roles and responsibilities can you identify for members of the health care team? What do you know about TeamSTEPPS® (https://www.ahrq.gov/teamstepps/index.html), and how would training in these strategies and tools improve team performance? How does teamwork link to quality care? Would an analysis of team function in the clinical setting be beneficial as a quality improvement study?

Safety/Evidence-Based Practice: How is safety actually and potentially impacted by team performance? Doesn't having team members with varied personal, educational, and experiential backgrounds provide an opportunity for individualizing care using the best-known evidence? When considering beginning clinical knowledge, what is the value of brainstorming knowledge and agreeing on a plan of care before acting?

Informatics: How do we integrate informatics when delivering patient care? How does the technology available increase our access to varied and valuable information? How do we make space during a crisis to gather information from the person observing the monitor, looking in the EHR, completing a medication calculation, or pulling up a protocol? How do we leverage communication and technology information to provide safe, quality care (even to a simulated patient)?

Recall **Ashley Dotski**, the student nurse who is looking to hone her critical thinking skills. Ashley could consider completing a PrepU assignment on the concept of Critical Thinking to identify strengths and gaps in her understanding of the definitions and applications of critical thinking in nursing.

Clinical Reasoning

Like critical thinking, clinical reasoning has multiple layers and context-based descriptions. Reasoning, in general, is not

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

unique to nursing. Hypothetico-deductive reasoning is a component of Piaget's cognitive development theory and relates to the formal operational stage in adolescence (Piaget & Inhelder, 1969). Transitioning from concrete thinking to abstract thinking allows for hypothesis testing and considering elements outside of what is immediately perceived. Deductive reasoning relies on applying widely accepted knowledge and principles to a model or a combination of models to solve problems—this is referred to as *backward reasoning*. Proving your point by testing identified theories or hypotheses and predicting consequences utilizes deduction. Inductive reasoning requires observing, then drawing conclusions—this is referred to as *forward reasoning*. Inductive reasoning processes require the ability to recognize patterns and connections and form hypotheses and theories. Inductive reasoning requires experience, knowledge, a holistic view, intuition, and organized thinking. Although deductive and inductive both have value, inductive reasoning is more often used by expert practitioners (Shin, 2019).

The American Association of Colleges of Nursing (AACN, 2021) positions clinical reasoning as a precursor to clinical judgment, and considers critical thinking, knowledge from nursing and other disciplines, and clinical reasoning as foundational to clinical judgment and the associated clinical decision making (CDM). Specifically, **clinical reasoning** is defined as "thought processes that allow healthcare providers to arrive at a conclusion" (AACN, 2021, p. 62). Alfaro-LeFevre (2020a) defines clinical reasoning and decision making as "the process you use to think about patient problems in the clinical setting" (p. 8). This idea of viewing clinical reasoning as the *process* of thinking that results in a clinical judgment is fairly accepted in nursing. Although critical thinking is relevant in everyday life (although in a different form than what we consider critical thinking in health care), clinical reasoning occurs in the clinical setting. For example, clinical reasoning is required when providing thoughtful, person-centered care; when engaging in quality improvement projects; when integrating evidence-based practice; when providing teaching; and in many other instances (Alfaro-LeFevre, 2020a and 2020b). Think about it this way: critical thinking may be used to access the EHR and to learn to navigate through the screens, but clinical reasoning is used to decide what you should review, when to review it, and how each piece of data relates to the others to create a clinical picture.

Clinical Judgment

Clinical judgment is the result or observed outcome of critical thinking and decision making (NCSBN, 2019a). AACN (2021) defines clinical judgment as "the skill of recognizing cues regarding a clinical situation, generating and weighing hypotheses, taking action, and evaluating outcomes for the purpose of arriving at a satisfactory clinical outcome" (p. 62). Hopefully you noticed that this definition mirrors the nursing process, which is discussed later in this chapter. As you move through the rest of this chapter, consider the overlap and use of the terms critical thinking, clinical reasoning, clinical decision making, and clinical judgment. Memorizing definitions is not the goal. Rather, your first goal is to understand how the concepts relate to your learning, the teaching strategies, your assignments, the exams, and other course-related activities. Then apply the concepts in the clinical setting and consider how they are fundamental to nursing practice. Finally, it is important that you acknowledge the impact your clinical judgment has on patient outcomes.

Situational Awareness

Situational awareness (SA), also referred to as *situation awareness*, is "the perception of the elements in the environment in a volume of time and space, the comprehension of their meaning and the projection of their status in the near future" (Endsley, 1995, p. 36). Originally used in training crews of military aircraft and in other tactical and strategic systems, SA is known to increase in difficulty as the complexity and dynamic nature of an environment increases (Endsley, 1995). Picking up on the (sometimes subtle) cues that indicate a patient is deteriorating, recognizing the implications of these assessments, and notifying the team to implement a protocol demonstrates how the idea of SA is applied in health care. Nurses face significant challenges when managing the delivery of thoughtful, person-centered care with the complexities in the health care environment, increased workload and associated cognitive load, frequent interruptions, and ongoing distractions (Walshe et al., 2021). Novice nurses tend to have a narrower focus than their more experienced counterparts and focus on tasks and cues immediately available. Experienced nurses, who have developed intuition, are continually scanning the environment to prioritize their nursing actions (Sitterding et al., 2014).

Protocols, early warning systems embedded in the EHR, and standardized hand-off tools all serve to facilitate the situational awareness of health care teams and address safety issues in the clinical environment. Nurses need to be involved in the development and implementation of these systems to ensure they are feasible and address the needs of nurses. For example, there is debate over whether the amount of documentation in the computer required to trigger a warning in the EHR interferes with the nurse's ability to spend time with the patient and instinctively use their nursing skills to recognize important cues. It takes time to learn to balance nursing clinical judgment with our reliance on information technology and communication tools that provide safety checklists and protocols. **Cognitive load** is a term used to reference the amount of information a person can hold in their memory at one time. Although related to multitasking, the reprioritization and refocusing nurses do on an ongoing basis is unique and mentally taxing, which is why factors such as patient acuity and staffing levels are important to consider. Developing schema and strategies to manage the cognitive load is essential for maintaining SA.

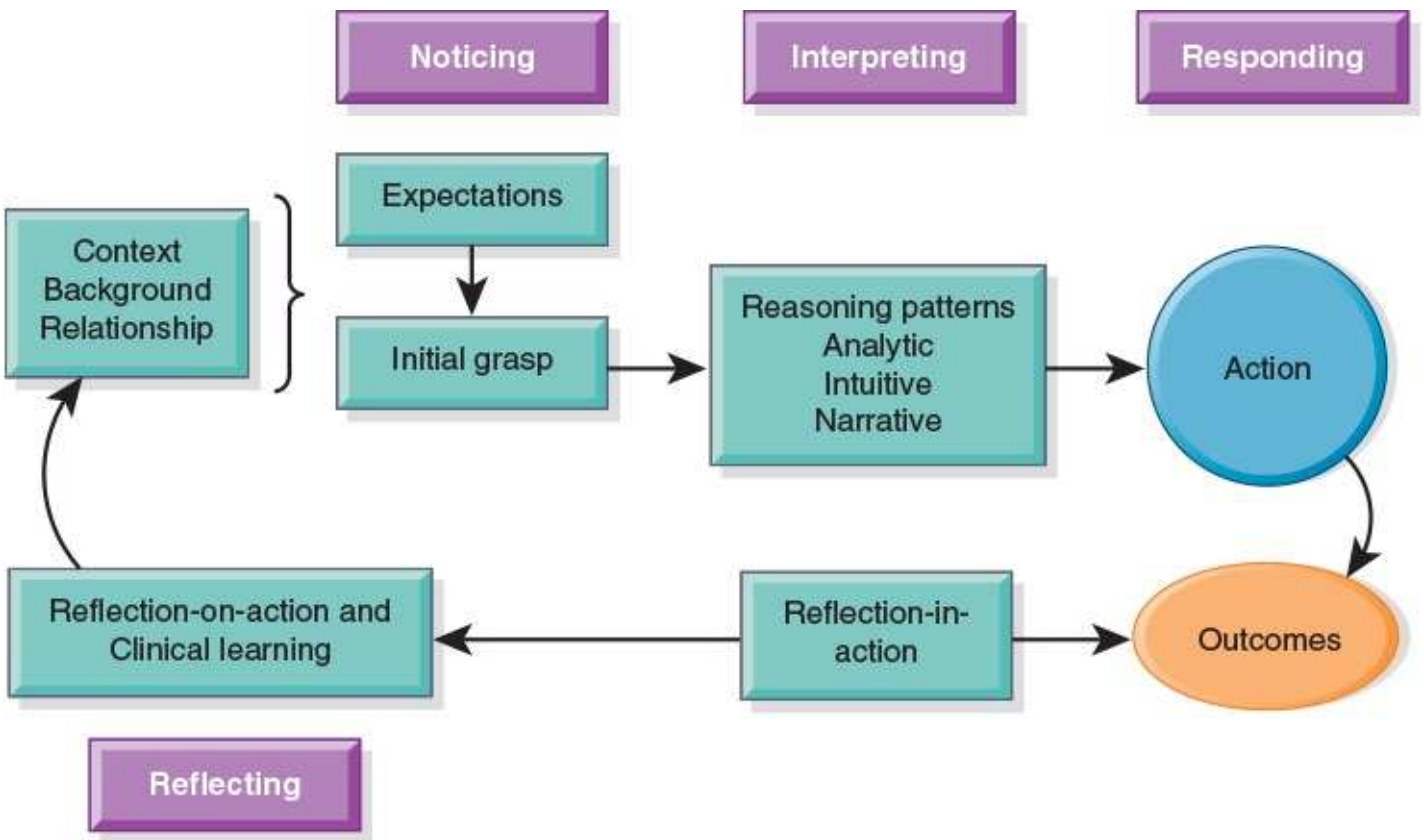

FIGURE 14-1. Clinical Judgment Model. (*Source:* Adapted with permission from Tanner, C. A. [2006]. Thinking like a nurse: a research-based model of clinical judgment in nursing. *Journal of Nursing Education*, *45*[6], 204–211. https://doi.org/10.3928/01484834-20060601-04)

Generally speaking, SA is required prior to decision making and clinical judgment (Fore & Sculli, 2013), which is why the term is relevant to health care professionals. As you review the clinical judgment models described in this chapter, look for elements of SA, specifically the concepts of perception, comprehension, and projection.

MODELS RELATED TO CLINICAL JUDGMENT

Nursing draws on developments from other disciplines and generates our own models to facilitate the development of clinical judgment. Although what follows is not an exhaustive discussion, we will highlight a few key models and frameworks that will support you in your development of clinical judgment.

Tanner's Clinical Judgment Model

When nurse educators think about developing clinical judgment, one of the first models referenced is Tanner's (2006) Clinical Judgment Model. This research-based model accounts for the impact the nurse's knowledge, experience, and values have on assessment and action in a situation; the importance of knowing our patients and considering their perspectives; the influence of context and culture on a situation; the recognition that nurses typically use more than one reasoning pattern; and the importance of reflection to foster the development of clinical knowledge and improving clinical reasoning (Tanner). Clinical judgment for this model is defined as "an interpretation or conclusion about a patient's needs, concerns, or health problems, and/or the decision to take action (or not), use or modify standard approaches, or improvise new ones as deemed appropriate by the patient's response" (Tanner, 2006, p. 204). The model is provided in Figure 14-1.

The core elements of the model include:

- Noticing: initial grasp and perceptions of the situation that are impacted by context, the nurse's practical experience, knowledge of expected versus unexpected data, ethical perspectives, and the nurse–patient relationship
- Interpreting: attributing meaning to the data through multiple reasoning patterns
- Responding: deciding on an action (or inaction) and monitoring outcomes
- Reflecting: in-action and on-action

What makes this model the go-to for many student nurses and nurse educators is that the first three components of the model are supported by reflection. *Reflection in-action* occurs when actively engaged in the situation and during ongoing monitoring and assessment; *reflection on-action*, which mirrors a debrief or post-conference, occurs after the situation and drives clinical learning. Note that this model is cyclical, like the experiential learning model (further described on p. 394), which indicates that the learning that occurs informs future experiences. Although there are certainly times when nurses do not consciously move through each step of this model, it reflects the way nurses arrive at decisions and, more importantly, the way student nurses develop clinical judgment.

Based on Tanner's Clinical Judgment Model, Lasater (2007) developed and tested a rubric to describe the development of clinical judgment, the Lasater Clinical Judgment Rubric (LCJR; Table 14-1 on page 386).

Table 14-1 Lasater Clinical Judgment Rubric

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	EXEMPLARY	ACCOMPLISHED	DEVELOPING	BEGINNING
Effective noticing involves:				
Focused observation	Focuses observation appropriately; regularly observes and monitors a wide variety of objective and subjective data to uncover any useful information	Regularly observes and monitors a variety of data, including both subjective and objective; most useful information is noticed; may miss the most subtle signs	Attempts to monitor a variety of subjective and objective data but is overwhelmed by the array of data; focuses on the most obvious data, missing some important information	Confused by the clinical situation and the amount and kind of data; observation is not organized and important data are missed, and/or assessment errors are made
Recognizing deviations from expected patterns	Recognizes subtle patterns and deviations from expected patterns in data and uses these to guide the assessment	Recognizes most obvious patterns and deviations in data and uses these to continually assess	Identifies obvious patterns and deviations, missing some important information; unsure how to continue the assessment	Focuses on one thing at a time and misses most patterns and deviations from expectations; misses opportunities to refine the assessment
Information seeking	Assertively seeks information to plan intervention; carefully collects useful subjective data from observing and interacting with the patient and family	Actively seeks subjective information about the patient's situation from the patient and family to support planning interventions; occasionally does not pursue important leads	Makes limited efforts to seek additional information from the patient and family; often seems not to know what information to seek and/or pursues unrelated information	Is ineffective in seeking information; relies mostly on objective data; has difficulty interacting with the patient and family and fails to collect important subjective data
Effective interpreting involves:				
Prioritizing data	Focuses on the most relevant and important data useful for explaining the patient's condition	Generally focuses on the most important data and seeks further relevant information but also may try to attend to less pertinent data	Makes an effort to prioritize data and focus on the most important, but also attends to less relevant or useful data	Has difficulty focusing and appears not to know which data are most important to the diagnosis; attempts to attend to all available data
Making sense of data	Even when facing complex, conflicting, or confusing data, is able to (a) note and make sense of patterns in the patient's data, (b) compare these with known patterns (from the nursing knowledge base, research, personal experience, and intuition), and (c) develop plans for interventions that can be justified in terms of their likelihood of success	In most situations, interprets the patient's data patterns and compares with known patterns to develop an intervention plan and accompanying rationale; the exceptions are rare or in complicated cases where it is appropriate to seek the guidance of a specialist or a more experienced nurse	In simple, common, or familiar situations, is able to compare the patient's data patterns with those known and to develop or explain intervention plans; has difficulty, however, with even moderately difficult data or situations that are within the expectations of students; inappropriately requires advice or assistance	Even in simple, common, or familiar situations, has difficulty interpreting or making sense of data; has trouble distinguishing among competing explanations and appropriate interventions, requiring assistance both in diagnosing the problem and developing an intervention
Effective responding involves:				
Calm, confident manner	Assumes responsibility; delegates team assignments; assesses patients and reassures them and their families	Generally displays leadership and confidence and is able to control or calm most situations; may show stress in particularly difficult or complex situations	Is tentative in the leader role; reassures patients and families in routine and relatively simple situations, but becomes stressed and disorganized easily	Except in simple and routine situations, is stressed and disorganized, lacks control, makes patients and families anxious or less able to cooperate

Clear communication	Communicates effectively; explains interventions; calms and reassures patients and families; directs and involves team members, explaining and giving directions; checks for understanding	Generally communicates well; explains carefully to patients; gives clear directions to team; could be more effective in establishing rapport	Shows some communication ability (e.g., giving directions); communication with patients, families, and team members is only partly successful; displays caring but not competence	Has difficulty communicating; explanations are confusing; directions are unclear or contradictory; patients and families are made confused or anxious and are not reassured
Well-planned intervention/ flexibility	Interventions are tailored for the individual patient; monitors patient progress closely and is able to adjust treatment as indicated by patient response	Develops interventions on the basis of relevant patient data; monitors progress regularly but does not expect to have to change treatments	Develops interventions on the basis of the most obvious data; monitors progress but is unable to make adjustments as indicated by the patient's	Focuses on developing a single intervention, addressing a likely solution, but it may be vague, confusing, and/or incomplete; some monitoring may occur
Being skillful	Shows mastery of necessary nursing skills	Displays proficiency in the use of most nursing skills; could improve speed or accuracy	Is hesitant or ineffective in using nursing skills	Is unable to select and/ or perform nursing skills

As you can see in Lasater's rubric, the four components of Tanner's model each have three to four dimensions that further explicate each of the four components. These 11 total dimensions are similar to competencies insomuch as they are very direct, clear, and action-oriented (see the far-left column of the rubric). Like any rubric you may have used in previous coursework to guide your development of an assignment and your teacher's grading of the assignment, a scale defines and describes level of accomplishment, which may be associated with points or a grade. In the LCJR, four levels of performance are possible: *exemplary*, *accomplished*, *developing*, or *beginning* (top row of the rubric). Detailed descriptions of actions taken by a student nurse who is deemed exemplary, accomplished, developing, or beginning for each of the 11 dimensions are included to guide use of the rubric. Although originally designed for the evaluation of a single simulation scenario, the rubric outlines the expectations of student nurses and provides a concrete way to show progression in the development of clinical judgment. A rubric like this is very valuable when used over the duration of a nursing program. Your program likely has a clinical evaluation tool that may reflect some of the ideas outlined in the LCJR. Your faculty will also evaluate your performance in the skills laboratory or simulation setting according to predefined standards that reflect expected development, expected performance, and the culture and values of your program. As an aside, learning to use a rubric early in your career will assist you not just in school; rubrics are often associated with grants, publishing scholarly works, a clinical ladder or evaluation tool at work, and many other instances where standardized evaluation is required.

Developing Nurses' Thinking Model

The Developing Nurses' Thinking (DNT) model has undergone several revisions and has been tested in several studies (Jensen et al., 2014; Tesoro, 2012; Tesoro et al., 2021). The initial model considered four evidence-based concepts: domain knowledge that includes the nursing process, discrete critical thinking processes, safety issues, and repeated practice of the model to develop habits (Tesoro, 2012). The latest iteration used by Tesoro et al. (2021) contains the same concepts but emphasizes the level of actual or potential danger and demonstrates the cyclic nature of the nursing process. The model identifies 17 critical thinking processes including information seeking, contextual perspective, predicting, discriminating, intuition/pattern recognition, and creativity. The DNT model was used to develop clinical reasoning prompts designed to assist student nurses in making clinical judgments on a case study. Although the prompts primarily increased confidence, one of the things brought to light by research using the DNT model is the value and necessity of threading clinical judgment models and frameworks into curricula to provide students repeated opportunities to develop critical thinking, clinical reasoning, and clinical judgment (Tesoro et al., 2021). Your school may integrate a clinical judgment model (or a combination of models) into their lessons, reflections, and evaluation tools to allow for repeated exposure to these concepts, to provide a framework for you, and to track your growth.

California Critical Thinking Disposition Inventory

The California Critical Thinking Disposition Inventory (CCTDI) measures the willingness of an adult learner to think critically. Based on an expert consensus in the American Philosophical Association (APA) Delphi Report on critical thinking (Facione, 1990), the CCTDI describes the characteristics of an ideal critical thinker and measures seven attributes:

the disposition toward truth-seeking or bias, toward open-mindedness or intolerance, toward anticipating possible

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

consequences or being heedless of them, toward proceeding in a systematic or unsystematic way, toward being confident in the powers of reasoning or mistrustful of thinking, toward being inquisitive or resistant to learning, and toward mature and nuanced judgment or toward rigid simplistic thinking (Insight Assessment, 2021).

The CCTDI provides insight into the tendency of a person to engage in life-long or career-long learning, which is good information for a student nurse who, based on the everchanging, complex health care environment, is never done learning.

National Council of State Boards of Nursing

"National Council of State Boards of Nursing (NCSBN) is an independent, not-for-profit organization through which nursing regulatory bodies act and counsel together on matters of common interest and concern affecting public health, safety and welfare, including the development of nursing licensure examinations" (NCSBN, 2022, p. 1). Most nurse educators and nursing students associate NCSBN with the standardized tests required for nursing licensure, NCLEX-PN and NCLEX-RN. With any update of the exam, an associated test plan is posted online for nurse educators to use to ensure concepts are addressed in the curriculum. For example, in addition to outlining key concepts, the test plans highlight specific diagnostics and laboratory values that students need to know for the exam (as opposed to laboratory values expected to be referenced). You can access the most up-to-date test plans at https://www.ncsbn.org/testplans.htm; this is a good resource to access when crafting a study plan for the exam. NCSBN released clinical judgment and action models that are directly related to NCLEX.

Recall **Daniel Ramirez**, the student nurse who benefits from information about the teacher and exam when preparing a study plan. Daniel can start integrating NCLEX-style practice questions into his study plan early in the nursing program to increase his comfort with the types of questions he will be asked on the licensure exam.

Clinical Judgment Measurement Model

Although not a clinical judgment model, NCSBN's Clinical Judgment Measurement Model (CJMM) works behind the scenes of the standardized test required for nursing licensure upcoming new version of the NCLEX, the Next Generation NCLEX (NGN), set to release in 2023 to evaluate the development of clinical judgment (see Fig. 14-2 for the NCSBN Clinical Judgment Measurement Model). Layers 0–2 of the model emphasize how clinical judgment informs the clinical decisions made to address the client's needs. Evaluation of those decisions determines if the processes in layers 3 and 4 should be completed again. Layers 3 and 4 are focused on expected behaviors of a student in a specific clinical or case scenario. These behaviors are directly related to what NCSBN deems an appropriate clinical decision on the NGN (NCSBN, 2019a). Although this action model (described more fully in the next section) and measurement model are relatively new, they are related to the core elements of the nursing process, which have guided nursing education and practice for decades. See Figure 14-3 for the NCSBN Clinical Judgment Overview that overlays the five steps of the nursing process with the six NCSBN cognitive skills.

Clinical Judgment Action Model

The Clinical Judgment Action Model (CJAM) developed by NCSBN is used in the context of the 2023 release of the NGN. The action model aligns the six cognitive operations from layer 3 of the CJMM (recognize cues, analyze cues, prioritize hypotheses, generate solutions, take actions, and evaluation outcomes) with specific situational factors from layer 4 including environmental, client observation, medical record, and time pressure cues (NCSBN, 2019a). The NCSBN model is based on the humanistic–intuitive, information-processing, and cognitive continuum cognitive theories and models (Betts et al., 2019; see p. 394). This textbook, your faculty, and the NGN utilize evolving case studies to walk through these six steps in a clinical scenario that includes specific cues. Make sure you spend time on the evolving cases embedded at the end of eight chapters in this book (see p. 1081 for an example).

Forming, refining, and evaluating hypotheses in the context of clinical judgment challenges student nurses because they are learning how to simultaneously follow a systematic thought process to assess, prioritize, and diagnose, while allowing for creativity and individualization to meet the needs of the patient. Consider what is meant and how to

describe specific elements of the CJAM. For example, when we talk about generating solutions, what you are actually doing is determining the desired outcomes, exploring the evidence to determine the best solution(s), identifying what resources are needed (Billings, 2019; Hensel & Billings, 2020), thinking about social determinants of health (SDoH) that may limit potential solutions, acknowledging your bias when considering options, and balancing creative solutions with realistic options.

Keep in mind that although the 2023 NGN requires your faculty to restructure some test items in your curriculum, you benefit from their transparency, instruction, and opportunities for practice because you must pass the NCLEX for licensure. However, nursing education addresses more than the NCLEX—nurse educators are working with you to facilitate your development as a practicing nurse who thrives in the complex health care environment. The development of clinical judgment is foundational and draws on your understanding and application of best evidence, situational awareness, advances in technology and communication, person-centered care (that includes SDoH, a holistic perspective, the impact of health policy, families and others close to the patient), and your ability to access and use your resources. Think beyond the NCLEX and classroom instruction. Integrate what you learn from your interactions with a live EHR in the clinical practice setting or the simulated EHR (such as DocuCare) used for simulation, laboratory, and other assignments. Integration of this technology is essential for clinical practice, which is why navigation of resources such as this may be embedded in the NGN and should become part of your study plan. Access and use various elements associated with your textbook to consider what you are studying from different perspectives, applications, and foci. Keep in mind that nursing programs intentionally include laboratory, simulation, and clinical as part of the preparation of students—let these experiences assist you when presented with evolving cases; virtual simulations; and, most importantly, live clinical situations. Think about this the other way, too—use the opportunities presented in simulation and that you encounter in clinical rotations to round out your understanding of complex diseases and syndromes. When reading a test question, use what you have learned from clinical experiences to mentally enter the scenario, consider the facts as written, and pay special attention to cues intentionally embedded in the questions to situate yourself within the case presented and choose the best answer.

Nursing Process—Thinking Like a Nurse

In most nursing programs, you will be introduced to clinical judgment through an exploration of the nursing process (Yura & Walsh, 1988). One of the most important things to understand is that the nursing process is not the same thing as a care plan. The nursing process outlines the way nurses think; it represents the unique, shared language of nurses. The care plan is used as a teaching tool to explicate the steps the nurse mentally goes thorough when developing, delivering, and evaluating a patient's individualized plan of care. Nurses do not walk into a patient room and announce the steps as they go through them, saying, "I am now going to assess and then cluster data!" But nurses *do* organize their thoughts using assessment, diagnosing or identifying an actual or potential problem, planning, identifying interventions with rationale, and evaluation (ADPIE). This nursing process represents a mental model (an organized way of thinking that shapes our worldview and helps us to understand complex aspects of a situation) that guides our assessments and behaviors. The formal design of the nursing process model fosters a predictable approach that is patient specific but draws on previous experience, requires support of our actions with recent evidence, and promotes reflection and adaptation in the evaluation phase. The table-based care plan or related concept map provides students the opportunity to go through the linear ADPIE process intentionally to formalize this organized way of thinking like a nurse. The individualization of care plans using the nursing process requires clinical judgment. One of the things students must identify in patient care is actual or potential problems and prioritize them appropriately. Examples of actual or potential patient health problems and needs are provided for students throughout the chapters in this textbook in the Actual or Potential Health Problems and Needs boxes. Review Box 14-1 for guidelines on how to maximize your use of these boxes.

Box 14-1 **How to Use Actual or Potential Health Problems and Needs Boxes**

Identifying a Problem or Need

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
For this text, these health problems or needs come from one of the two sources below the table. However, in the clinical setting, most electronic health records (EHRs) include an auto-populated list that an interprofessional team member can draw upon to craft a plan of care that reflects best practice,	Etiology requires determining the underlying cause—what is the root of the problem or need. Try not to use another problem or medical diagnosis here. Ask yourself what is going on with the patient to cause this problem or need. For example, we would not use chronic obstructive airway disease (COPD; a medical	These are the signs and symptoms of the problem or need (not the etiology). For example, if you are going to identify a problem related to airway clearance (mechanical issue), be sure to describe the mucus and cough; if you are prioritizing a problem related to gas exchange (chemical issue), be sure to

takes standard reimbursement into account, and can be individualized for each patient.	diagnosis) here. We could, however, state chronic mucus production, air trapping, and increased airway reactivity.	include a pulse oximetry reading and arterial blood gas results. Be sure to include objective and subjective data.	

Source: International Council of Nurses (ICN). (2019). *Nursing diagnosis and outcome statements*. https://www.icn.ch/sites/default/files/inline-files/ICNP2019-DC.pdf; Wolters Kluwer. (2020). *Problem-based care plans*. In Lippincott Advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

Identifying a health problem or need, breaking down the etiologic components, and associating the correct signs and symptoms requires critical thinking and clinical reasoning. Prioritizing them based on the situation, acuity, and hierarchy of problems or needs requires clinical judgment. For example, pain may be chronic and secondary to a patient learning to manage a new complex medication regimen; but if that pain is acute, severe, and consuming, learning a new complex medication regimen may not be able to occur until pain is resolved.

Concept maps (discussed in Chapter 17) provide a means of integrating pathophysiology, evolving clinical manifestations, laboratory values and diagnostics, and elements of the traditional care plan. Although concept maps can take many forms, they should show progression (i.e., *X leads to Y*) and demonstrate relationships. In a free-form map, think about placing risk factors, pathophysiology, and disease processes at the top of the map; connecting to clinical manifestations, disease sequelae (consequences), and related problem identification in the middle of the map; and ending with interventions and outcomes at the bottom of the map. Concept maps are very valuable when considering the care of a patient with complex disease processes that are interrelated (see the concept map on p. 1045).

DEVELOPING COMPETENCY IN NURSING PRACTICE

Clinical judgment is foundational to every action taken by a nurse from identifying a problem and associated interventions to advocating for a patient whose voice needs to be heard. These actions, which are supported by clinical judgment, often fall into a competency model. Framing educational outcomes as competencies makes them measurable. In nursing, we are very outcome-focused with our patients and in our process of nursing education. These outcomes often focus on behaviors and attainment of certain thresholds. The American Nurses Association (ANA) *Nursing: Scope and Standards of Practice* (2021) defines a **competency** as "an expected level of performance that integrates knowledge, skills, abilities, and judgment" (p. 52). In many cases, competencies are complex and are not simply met once and checked off on a checklist—they require intentional reassessment by the educators and repeated exploration from different perspectives on the part of the student. Understanding education through the competency lens provides you perspective into checklists, rubrics, evaluation tools, rubrics, and even your program outcomes.

Competency Outcomes Performance Assessment Model

The Competency Outcomes and Performance Assessment Model (COPA; Lenburg et al., 2009) integrates essential practice competencies, outcomes and outcome statements, interactive learning strategies, and objective competency evaluation to validate competence in an effort to promote patient safety. This model was adapted in 2011 to prepare learners for effective role performance in the clinical practice environment by specifying specific, core behaviors in the affective, cognitive, and psychomotor realms that reflect competence (Lenburg et al., 2011; see Box 14-2 for an overview of these competencies). This concept of assessing students' knowledge, skills, and attitudes (KSAs) is a fundamental practice in nursing education. Asking what model is used for your competency evaluation informs your preparation and performance in simulation and skills laboratory settings. Knowing that educational rationale underpins the decisions made by faculty provides you context and will help you leverage resources provided to be successful in competency evaluation.

Professional Guidance

Nurse educators rely on standards of education and practice published by national leaders to guide their development of your curriculum and the associated methods of teaching. This development is intentional, collaborative, and often linked with accreditation of a nursing program.

Box 14-2 **The Eight Core COPA Practice Competencies With Examples of Related Affective, Cognitive, and Psychomotor Skills**

1. **Assessment and Intervention Skills**
   a. Safety and protection
   b. Assessment and monitoring
   c. Therapeutic treatments and procedures

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

2. **Communication Skills**
   a. Oral skills
      1. Talking, listening, with individuals
      2. Interviewing; history taking
      3. Group discussion, interacting
      4. Telling, showing, reporting
   b. Writing skills
      1. Clinical reports, care plans, charting
      2. Agency reports, forms, memos
      3. Articles, manuals
   c. Computing skills (information processing; using computers)
      1. Related to clients, agencies, other authorities
      2. Related to information search and inquiry
      3. Related to professional responsibilities
3. **Critical Thinking Skills**
   a. Evaluation; integrating pertinent data from multiple sources
   b. Problem solving; diagnostic reasoning; creating alternatives
   c. Decision making; prioritizing
   d. Scientific inquiry; research process
4. **Human Caring and Relationship Skills**
   a. Morality, ethics, legality
   b. Cultural respect; cooperative interpersonal relationships
   c. Client advocacy
5. **Management Skills**
   a. Administration, organization, coordination
   b. Planning, delegation, supervision of others
   c. Human and material resource utilization
   d. Accountability and responsibility; performance appraisals and QI
6. **Leadership Skills**
   a. Collaboration; assertiveness, risk taking
   b. Creativity, vision to formulate alternatives
   c. Planning, anticipating, supporting with evidence
   d. Professional accountability, role behaviors, appearance
7. **Teaching Skills**
   a. Individuals and groups; clients, coworkers, others
   b. Health promotion; health restoration
8. **Knowledge Integration Skills**
   a. Nursing, health care, and related disciplines
   b. Liberal arts, natural and social sciences, and related disciplines

Z., Spencer, T. S., Boyer, S. A., & Klein, C. J. (2011). Implementing the COPA model in nursing education and practice settings: Promoting competence, quality care, and patient safety. *Nursing Education Perspectives, 32*(5), 290–296. https://doi.org/10.5480/1536-5026-32.5.290

American Association of Colleges of Nursing

In 2021, the American Association of Colleges of Nursing (AACN) re-envisioned their *Essentials* (2021), a document that guides nurse educators in the United States and internationally. This is important to you as a student because the core tenets described in the *Essentials* surface in your course and program/student learning outcomes, especially if your program is accredited by the Commission on Collegiate Nursing Education (CCNE). "*The Essentials: Core Competencies for Professional Nursing Education* has been built on the strong foundation of nursing as a discipline, the foundation of a liberal education, and principles of competency-based education" (AACN, 2021, p. 2). Using a competency model originally designed for physicians (Englander et al., 2013), the *Essentials* outlines 10 domains with associated competencies and sub-competencies. These competencies and sub-competencies specify behaviors that students must demonstrate in their entry-level or graduate-level programs and are designed to translate to the practice of nursing today. This goal-focused perspective requires measurable attainment of competencies in distinct spheres of care. The domains are listed in Box 14-3.

In addition to the other *featured concepts* (communication; compassionate care; evidence-based practice; health policy; SDoH; ethics; and diversity, equity, and inclusion), the *Essentials* specifically addresses the integration of

clinical judgment. AACN's definition of clinical judgment recognizes clinical judgment as one of nursing's core attributes and foundational to the practice of nursing. There is an identifiable link between nursing knowledge that is rooted in evidence from myriad sources, nursing theory, and ways of knowing; knowledge gained from other disciplines and liberal education; critical thinking and reasoning; and CDM. This CDM, which is based on clinical judgment, directly impacts patient outcomes (AACN, 2021). AACN intentionally designed their competencies and sub-competencies to require consistent reiteration and consideration over the course of a nursing program, which means you will likely revisit the complex concepts outlined in the domains from many perspectives several times over your course of study. This guiding document articulates who we are and what we do as nurses, and provides a competencies-based map for both educators and students.

Box 14-3 **AACN *Essentials* Competency Domains**

- Domain 1: Knowledge for Nursing Practice
- Domain 2: Person-Centered Care
- Domain 3: Population Health
- Domain 4: Scholarship for Nursing Practice
- Domain 5: Quality and Safety
- Domain 6: Interprofessional Partnerships
- Domain 7: Systems-Based Practice
- Domain 8: Information and Healthcare Technologies
- Domain 9: Professionalism
- Domain 10: Personal, Professional, and Leadership Development

National League for Nursing

The competencies identified by the National League for Nursing (NLN, 2012, 2022) include human flourishing, nursing judgment, professional identity, and spirit of inquiry. Other key concepts integrated into the competencies-based education model address "context and environment; knowledge and science; personal and professional development; quality and safety; relationship-centered care; and teamwork" (NLN, 2021). The NLN Commission for Nursing Education Accreditation (CNEA) standards of accreditation build on the core values of NLN and these core competencies. Accreditation requires, in addition to other things, integration of experiential learning opportunities that "foster the acquisition of professional nursing values, encompassing, but not limited to, leadership skills, clinical reasoning and judgment, reflective thought, and ethically responsive care to diverse populations" (NLN CNEA, 2021, p. 37). The description of these professional values underscores the relevance of clinical judgment to good nursing care.

American Nurses Association

It is impossible to discuss competency in nursing education and not refer to the ANA for the *Nursing: Scope and Standards of Practice* (2021). The scope and standards publication articulates the necessity for nurses to use clinical judgment when identifying an actual or potential problem or need; when engaging in ethical decision making; and in conjunction with creative and critical thinking to evaluate the safety, quality, and effectiveness of nursing care (ANA, 2021). The scope and standards publication integrates several competency models including IPEC and QSEN, and specifically introduces the concept of structural competence. The 18 standards address each component of the nursing process (ADPIE, with outcome identification and planning addressed separately), ethics, advocacy, respectful and equitable practice, communication, collaboration, leadership, education, scholarly inquiry, quality of practice, professional practice evaluation, resource stewardship, and environmental health. Although not an exhaustive list, the guidance document also includes core competencies for each standard in relation to the scope of practice for registered nurses and graduate-level prepared registered nurses (ANA, 2021).

Quality and Safety Education for Nurses

Nursing education addresses collaborative, interprofessional-based initiatives that demonstrate responsiveness to national trends. Funded by the Robert Wood Johnson Foundation and developed by thought leaders in nursing, the competencies associated with Quality and Safety Education for Nurses (QSEN) outline the KSAs essential for prelicensure (and graduate) nurses. Using the Institute of Medicine (now the National Academy of Sciences, Engineering, and Medicine) competencies from 2003, the seminal QSEN work (Cronenwett et al., 2007) focused on six areas: patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics. The QSEN Institute website contains information on publications, conferences, and students resources you may find helpful: https://qsen.org/category/qs/.

You have likely noticed that this text intentionally includes threaded cases that focus on cultivating QSEN competencies. The QSEN boxes, such as the Reflective Practice display on p. 383 in this chapter, highlight the six main competencies to build your knowledge and ability to apply the competencies to a challenging clinical situation. We do

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

this by asking you to consider possible courses of action, evaluate possible outcomes, and relate this reflection to your development as a student nurse. The questions posed facilitate multiple ways of thinking, thus expanding your frame of reference. Use these boxes embedded throughout this text to orient yourself to the QSEN competencies that directly relate to the integration of concepts foundational to the development of clinical judgment.

Recall **Daniel Ramirez**, the student nurse who has expressed some anxiety with test-taking. Learning to integrate and apply the core QSEN concepts provides an opportunity for Daniel to think about clinical situations from several angles. This is a helpful skill when asked to prioritize actions.

Interprofessional Education Collaborative

The Interprofessional Education Collaborative (IPEC) core competencies were developed by a team of interprofessional health care collaborators who published their initial competencies in 2001 and updated them in 2016. Interprofessional competencies are defined by IPEC as: "Integrated enactment of knowledge, skills, values, and attitudes that define working together across the professions, with other health care workers, and with patients, along with families and communities, as appropriate to improve health outcomes in specific care contexts" (IPEC, 2016, p. 8). In addition to receiving support from myriad national professional organizations, their work informs curriculum and accreditation standards through a Health Professions Accreditors Collaborative (HPAC) that includes professional organizations from nursing, pharmacy, dentistry, osteopathy, public health, and medical education. Their competency-based interprofessional education framework includes the following four competencies (IPEC, 2016, p. 10):

. Work with individuals of other professions to maintain a climate of mutual respect and shared values. (Values/Ethics for Interprofessional Practice)
. Use the knowledge of one's own role and those of other professions to appropriately assess and address the health care needs of patients and to promote and advance the health of populations. (Roles/Responsibilities)
. Communicate with patients, families, communities, and professionals in health and other fields in a responsive and responsible manner that supports a team approach to the promotion and maintenance of health and the prevention and treatment of disease. (Interprofessional Communication)
. Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan, deliver, and evaluate patient/population-centered care and population health programs and policies that are safe, timely, efficient, effective, and equitable. (Teams and Teamwork)

Sub-competencies flesh out the specific, measurable competencies that comprise interprofessional collaboration as a standalone domain in curricula for health care professionals.

As you consider the competences from COPA, AACN, NLN, ANA, QSEN, and IPEC, you will likely notice some common threads and terms. Compare the competencies you have learned about with what you see in your course and program/student learning outcomes. Taking the time to understand the roots of your curriculum helps you to appropriately appreciate concepts and competencies designed to foster the development of your clinical judgment as a nurse, member of a profession, and collaborator.

CLINICAL DECISION-MAKING THEORIES, MODELS, AND FRAMEWORKS

Nursing is not alone in the endeavor to develop clinical judgment, although critical thinking and judgment take different forms and have different foci depending on the end goal. CDM is often based on a defined process or framework that provides a rational structure for student nurses. In nursing, our understanding and application of clinical judgment in CDM is rooted in several cognitive theories. The following examples represent just a few of the cognitive theories related to processing, reasoning, and decision making.

Humanistic–Intuitive Approach

The humanistic–intuitive approach is referenced by nurses with respect to Benner's (1982) novice to expert model of development. Novice nurses make clinical judgments that do not consider all of the contextual elements and rely on concrete, analytic methods and planning to inform their decision making. Most new graduates function at the novice level. In practicing nurses, that thinking expands with attainment of the next four levels (advanced beginner, competent,

proficient, and expert) and culminates in intuitive responses that seamlessly sort data and consider a holistic approach. Think about your experiences in clinical: do you ever wonder how the expert nurse seems to just instinctively know how to respond to unpredictable situations? Clinical judgment and decision-making models move from facts and rules to dynamic decision making with clinical experience (Benner, 1982; Betts et al., 2019).

Information-Processing Model

Another cognitive model that informs decision making mirrors the way we think of a computer processor. The information-processing model requires memory that is classified as sensory (collects and transforms), short term (temporary), and long term (more permanently stored). The information-processing model proposes a sequential way of thinking that involves encoding/input, storage, and retrieval/output. This cognitive theory proposes a straightforward way of considering human response to a stimulus that results in a response. Although a helpful model, we recognize that humans do not often process only one stimulus at a time, and we have emotions, histories, motivations, and other factors that can complicate this process.

Cognitive Continuum Theory

Originally posited by Hammond, a psychologist, in 1978 in relation to policy formation, the cognitive continuum theory (CCT) acknowledges and integrates both intuitive and analytical cognitive characteristics. The recognition that intuition influences CDM supports the delivery of creative, individualized, holistic, person-centered care. This intuitive aspect requires acknowledgment of potential biases and thoughtful use in conjunction with analysis to mitigate risk and errors (Standing, 2008). Standing (2008) built upon Hammond's original work and the work of Hamm (in medicine) to customize the cognitive continuum of clinical judgment and CDM for nursing that integrates intuition and analysis. What is significant about this model that will benefit student nurses is the consideration of the myriad activities performed by nurses from direct patient care to engaging in research and developing policy. It integrates accountability, ethical and professional comportment, competence, soundness of decisions, and consideration of other variables such as viability and time (Standing, 2008). Interprofessional team clinical judgment and CDM may be strengthened by the use of CCT by providing a shared language for CDM, mitigating potential bias, opening the door to a discussion of ideas based on experience, facilitating collaborative engagement in brainstorming solutions, and filling gaps in communication (Parker-Tomlin et al., 2017).

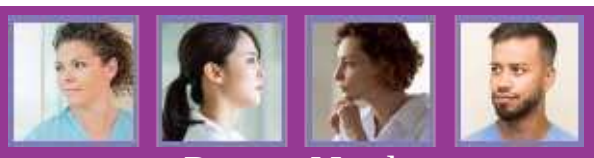
Rest Framework

Ethics underpins the cognitive theories and approaches, and there are many focused ethical decision-making models available to students and practitioners. Some models are rooted in deontology (duty-based), utilitarianism (greatest good for the greatest number), rights (Kant's categorical imperative), virtues (character based), or the feminist approach; these theories and associated approaches inform ethical decision-making frameworks that are often focused on consequences, duties, or virtue. Other models specifically draw on the beliefs, values, and obligations outlined in the professional code of ethics for that profession to craft a decision-making model tailored to their accepted professional roles and responsibilities (see Chapter 6 for more on ethics).

Based on the variation in nursing education and the complex health care environment, there is a recommendation to embed Rest's four-component model of moral reasoning into nursing curricula because it captures the cognitive processes that precede moral action and emphasizes the development of a person as a moral agent (Robichaux et al., 2022). The four components of the model include (Rest, 1982):

. Moral sensitivity: development of an awareness that there is an ethical issue; requires empathy and perspective-taking
. Moral judgment/reasoning: consideration of several courses of action to account for the potential impact on those involved (person-centered); occurs along with CDM and informs clinical judgment
. Moral motivation/focus: cognitive process of decision making that involves prioritizing (often) competing values
. Moral character: implementing a plan of action; related to professional identity formation

This last phase reflects integration of your professional and personal values and attributes, which is referred to as *wholeness of character* in our Code (ANA, 2015). The Code represents who we are as nurses, providing ethical guidance and supporting the profession of nursing. See Chapter 6 for a fuller discussion of the Code of Ethics for Nurses (ANA, 2015). As you progress in nursing school, keep in mind that decision-making schemata that you develop reflect your personal and professional role and identity formation.



INTEGRATING PREVIOUS KNOWLEDGE

Experiential learning reflects elements of competency models and clinical judgment models. In experiential learning, the cyclic nature of learning is driven by concrete experience, termed *prehension*, followed by *reflective observation*, which leads to the formation of abstract concepts that are then tested in new situations through experimentation, the integration of which is termed *transformation*. The process then begins anew with the active experimentation affecting the next experience (Kolb, 1984). Leveraging previously acquired knowledge in meaningful ways is essential for student nurses.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Educational Experience

Learning is cumulative. Lessons learned in your prerequisite courses inform your thinking, your perspectives, and your learning ethos. Ethos in this instance refers to the guiding beliefs, or ethics, of a group, person, or organization (Ethos, 2021). It is also a term used in rhetoric to reference Aristotle's description of ethos, which contains *phronesis* (wisdom or intelligence), *arete* (general moral virtue of your argument), and *eunoia* (the trust and rapport you establish with your audience), all of which are germane to establishing a writer's credibility, knowledge, and moral character (Gaiman, 2021). Although we are not going to dive into a philosophical debate on the value of rhetoric, nursing programs require students to build on previously acquired knowledge from the humanities, social science, and natural sciences (AACN, 2021). "The study of history, critical race theories, critical theories of nursing, critical digital studies, planetary health and climate science, politics, public policies, policy formation, fine arts, literature, languages, and the behavioral, biological, and natural sciences are key to the understanding of one's self and others, civil readiness, and engagement and forms the basis for clinical reasoning and subsequent clinical judgments" (AACN, 2021, p. 4). Developing empathy, a tolerance for ambiguity, the ability to take the perspective of others, and advocacy are all rooted in the liberal arts. One of the elements included in this textbook is a Poetry Nook—these poems were all written by a poet and nurse, Amy Haddid. They have been included to activate your creative side, to engage you in a different way, to change your thinking, and to provide personal insight in a way only poetry can.

Poetry Nook

Imaging Prep

You sigh, irritated with my veins.
A furtive glance at my other arm
spells uncertainty, or worse,
inexperience.

You run

your fingers down my arm,
resting in the pale antecubital
space, moving on above my wrist.
Veins roll and hide at
your touch. You commit

to the arm with the tourniquet,
poke the needle in and shimmy
the sheath, sliding the
sharp
back out. We wait for the
blood
to fill the tubing. When none

comes, you push the tubing
ahead a bit and hit a wall
in my vein. I gasp. You pause,
sigh again.

The flush flaming your neck
speaks of shame and pigheaded
resolve to stick with this site.

Each try burns as you jiggle
the tubing in and out. If you
keep at it,
I will wear your
handiwork
for weeks. I hiss
to let you know

it hurts.
Weighing the cost
of
crying out, *Stop.*

As you read each poem, consider the following reflection questions:

- How did this poem make you feel?
- Who is speaking in the poem? Why is their perspective important?
- What meaning do you attribute to the words in each stanza or section?
- Where is the nurse in the poem? Describe the attributes of the nurse (and other health care professionals) in the poem.
- How does the technical structure of the poem impact on your appreciation of the poem and on the clarity of the message of the poem?
- Write your own poem about a clinical experience.

Poetry Nook

Making Camp

The hall to intensive care is always
lit. At night, families and others,
unprepared, no gear or supplies,
make camp
in the waiting rooms, retreat
to corners, arrange makeshift
pillow forts. Lay claim to sofas,
drape and shape with sheets
to draw property lines. Downstream,
the more private consultation room,
sleeps two but reeks of bad news.
The tinny heave of the coffee machine
marks time over the family burrowed
under the information desk. They stay
close in case something changes,
hover at the end of the bed ten minutes
every hour. At dawn, they bend,
stiff and rumpled at the sinks, splash
water on their faces, avoiding any
glimpses of their mirrored lives, then
pat dry with harsh paper towels.
They lean against walls
to get the best signal,
texting, talking and casing
out who might still be there.

Poetry Nook

Blame Placing

Holding the scalpel in his gloved hand
like a baton, poised above the black crust
that was once her big toe—
tap, tap, tap, ready, begin.
The already hardened
medical students and residents

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

flank the maestro.
I stand by the head of the bed,
reach for the patient's hand,
hold it in both of mine.

The surgeon cuts away
at the decay
with constant clinical patter.
At first the patient does not flinch,
her hand held in mine.
She grips me, bites
her bottom lip, holds her breath
against the pain.

Now we're getting somewhere.
See how it bleeds. That's a good sign.
I whisper close to her ear,
Take a deep breath.
It will help ease the pain.
The smallest cry escapes
as she exhales. She turns crimson.

The performance interrupted,
he addresses me, *Nurse, let go of her hand.*
She grabs me tighter.
He drops the scalpel,
snaps off both sterile gloves.
I want to see you in the hall, now!
Extracting my hands,
I follow him out of the room.

He punctuates each word with a jab
to my chest, just above my name tag,
When I tell you to let go
of my patient, do it.

He pivots to leave. Not quite finished
he turns back, face so close to mine
I feel his breath, *You made things worse*
by babying her. Students in tow
who watched their mentor's show
follow.

I return to dress her bloody foot,
hope that there is something ordered
for her pain. *I'm sorry,*
I got you in trouble, she says.

Your view of education and your role as a student nurse evolves over the course of your education. Although you may have completed a learning style inventory and are well aware of your preferred education delivery mode, you will learn increased adaptability as you flex to assimilate new content from many different sources. For example, simulation requires flexing within a predictable and replicable model; clinical requires responding to individual and situational constraints; and didactic content may include small group work, specific technology-based applications that require more mental work from you up front, or more traditional lecture peppered with narratives, videos, and evolving case studies.

This blending of delivery models may not always suit your auditory, visual, or kinesthetic preference(s), but varied teaching and learning modalities help you consider different perspectives and strategies and allow for the development of multiple ways of knowing. Clinical judgment is informed by balancing empirical, aesthetic, personal, ethical (Carper, 1978), and sociopolitical (White, 1995) ways or patterns of knowing. Unknowing represents the nurse's ability to appreciate that they cannot and do not know the patient before their first encounter—the patient's perspective and their unique needs take precedence over our clinical habits and assumptions (Heath, 1998; Munhall, 1993). Depending on the

specific situation, nurses integrate the ways or patterns of knowing, sometimes emphasizing one component over another to improve patient outcomes.

Life Experience

We need diversity in nursing—our intention in health care is to mirror the populations we serve. Your unique experiences have shaped who you are as a person, and they are important. The goal is to help you develop your professional and personal identity within the confines of professional practice. This means that we foster decision making by enforcing school policies regarding late work, addressing areas that require attention through formal action plans, and partnering with you to define goals for your education. Any critical thinking and reasoning skills you already have in your repertoire will serve you well as we work together to adapt these skills for the clinical environment where our clinical judgment informs important clinical decisions that impact on the populations we serve.

Health Care Experience

Striking the balance between integrating your previous experience in health care to provide context for your burgeoning nursing practice and allowing your preconceived notions and role-specific knowledge to interfere with your development as a nurse requires intentionality. Instead of thinking, "that's not the way we do it in the real world," reframe your thinking to consider the underlying principles. Here is an example to consider: a nurse inserting an indwelling catheter does not follow the procedure you were shown when you onboarded as a patient care technician or does not strictly adhere to the carefully constructed checklist you memorized for check-off that week in lab. What you have to consider is whether the nurse adhered to the principles of sterility, the situational constraints (e.g., room set-up, available equipment, patient anatomy, nurse's dominant hand), and patient physical and psychological safety. Reframing your thinking to account for things you may not have considered at first glance builds your trust of the interprofessional team and fosters a collaborative approach. Nursing students benefit the health care environment by bringing positivity and elevating routine practice because of their questions regarding policy and procedure and constant observance. Ask questions, but keep in mind that your tone and words matter. Recognize that learning the steps is essential when practicing the urinary catheterization skill for the first time, but the ability to adapt while adhering to the underlying infection-control principles demonstrates clinical judgment.

Recall **Kallie McDonald**, the paramedic transitioning to nursing. As a paramedic, Kallie completed an associate degree and is familiar with a defined scope of practice related to licensure. Because of the comprehensive response expected of the paramedic, Kallie has developed clinical judgment skills and routinely engages in complex decision making. Kallie's focus should be on honing those skills and integrating them into their evolving professional identity as a nurse.

IMPORTANCE OF REFLECTION

While in nursing school, you are going to be asked to formally reflect, often in writing, more than you expect. The practice of reflection is different than journaling—it is intentional, focused, directed, and purposeful. Guided reflection templates or guidelines may reflect your program/student learning outcomes, course outcomes, competencies or sub-competencies, or other measurable elements. For example, Nielsen et al. (2007) developed a Guide for Reflection that is based on Tanner's Clinical Judgment Model (Box 14-4 on page 398).

This Reflection Guide provides prompts in the form of both questions and directives that guide the thinking of the student nurse. Take a look under the Interpreting header. Do you see how this guide forces the student to arrive at a conclusion? There is also an expectation that rationales are provided, which integrates evidence-based practice. Now look under the Responding header. Do you see how this includes prompts that guide your thinking of thoughtful, person-centered interventions? Pay special attention to the second question regarding the identification of stressors: this question provides the space and grace for the student nurse to reflect on their feelings. The last four questions on the guide drive home the necessity of reflecting on learning. You will see these headers in the Thoughtful, Person-Centered Practice: Challenging Topics boxes (for example, on pages 398–399) included throughout this textbook. Take the time to consider the challenge presented and walk through the questions to reflect deeply and with purpose.

Simulation debriefing (or debrief) is another touch point for reflection. Reflection during a debrief is often done

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

verbally with groups of participants. A simulation debrief facilitator typically uses a semi-structured debriefing guide that prompts pointed questions to engage participants and allow them to dialogue, vent, critique, celebrate, and tie learning back to the clinical practice setting. If serving as a participant observer in a simulation (not directly involved with the scenario), your perspective provides additional information for the team to consider, especially during the debrief. Facilitators often require specific training to integrate team dynamics into a debriefing session. An individual written reflection may also be included with a simulation experience. This may be used before the group debrief to allow individual participants time to process and organize their thoughts and feelings, or after the debrief to reinforce learning. Knowing the information is very different from applying it in the moment in response to a specific scenario designed to elicit a response from you. The debrief and/or reflection provides the space and mechanism for focusing on the process of clinical reasoning ("What did you do next? What were you thinking when you made that decision?") to guide you in your ability to make sound clinical decisions based on clinical judgment ("How are you going to apply what you learned to your clinical practice?").

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

This section is found in each chapter of this textbook to foster intentional reflection and foster clinical reasoning and clinical judgment related to the specific content of the chapter. The questions are designed to help you reflect and apply critical thinking skills to develop your abilities related to clinical judgment. Since this entire chapter was focused on clinical judgment, instead of providing prompts, we will explore why the questions are included in each chapter.

. The first question in the clinical chapters refers you to the concept map, care plan, or evolving case study. The evolving case studies are modeled after a template provided by NCSBN, in which a scenario is interrupted by questions designed to hone your ability to recognize cues, prioritize cues, prioritize hypotheses, generate solutions, take action, and evaluate outcomes.
. The remaining questions are designed to deepen your critical thinking, explore your process of clinical reasoning, and employ CDM based on clinical judgment.

Box 14-4 **Guide for Reflection Using Tanner's Clinical Judgment Model**

Instructions

This Guide for Reflection is intended to help you think about a given clinical situation you have encountered during the past week and your nursing response to that situation. The situation can be a specific physiologic patient problem, such as an elevation in temperature, respiratory difficulty, or electrolyte imbalance. You may choose to describe a situation involving a patient's family. The situation can be a description of your role in interdisciplinary problem solving. The reflection situation may describe an ethical issue you encountered in practice. Use the guide for reflection as a way to tell the story of the situation you encountered.

The guide provides you with a way of thinking about care that supports the development of your clinical judgment. Although there are many ways of organizing your thinking about patient care and professional nursing practice, Tanner's (2006) Clinical Judgment Model provides the framework for the questions in this guide.

Introduction

Describe a nursing situation you encountered this week (see the instructions above).

Background

- Describe your relationship to the patient at the time you noticed the situation (e.g., previous contact with patient and/or family, the quality of your relationship).
- Consider experiences you have had that helped you provide nursing care in the situation. Describe your formal knowledge (e.g., physiology, psychology, communication skills), previous nursing experiences with a similar problem, and/or personal experiences that helped guide you as you worked with the patient.
- Describe your beliefs about your role as the nurse in working on the situation.
- Describe any emotions you had about the situation.

Noticing

- What did you notice about the situation initially?
- Describe what you noticed as you spent more time with the patient and/or family.

Interpreting

- Describe what you thought about the situation (e.g., its cause, potential resolutions, patterns you noticed).
- Describe any similar situations you have encountered in practice before. Describe any similarities and

differences you observed when compared with the current situation.
- What other information (e.g., assessment data, evidence) did you decide you needed as you considered the situation? How did you obtain this information? What help with the problem did you get from your preceptor?

Your conclusion: What did your observations and data interpretation lead you to believe? How did they support your response to the situation? Include pertinent pathophysiology and/or psychopathology.

Responding

- After considering the situation, what was your goal for the patient, family, and/or staff? What was your nursing response, or what interventions did you do? List all actions that you took.
- Describe stresses you experienced as you responded to the patient or others involved in the situation.

Reflection-in-Action

- What happened? How did the patient, family, and/or staff respond? What did you do next?

Reflection-on-Action and Clinical Learning

- Describe three ways your nursing care skills expanded during this experience.
- Name three things you might do differently if you encounter this kind of situation again.
- What additional knowledge, information, and skills do you need when encountering this kind of similar situation in the future?
- Describe any changes in your values or feelings as a result of this experience.

Source: Nielsen, A., Stragnell, S., & Jester, P. (2007). Guide for Reflection Using the Clinical Judgment Model. *Journal of Nursing Education*, *46*(11), 513–516. https://doi.org/10.3928/01484834-20071101-06

Thoughtful, Person-Centered Practice: Challenging Topics

Artificial Intelligence (AI) and Informatics in Health Care

Many controversial issues make it challenging to know how to respond as a professional nurse in select scenarios. Often, the nurse's personal and/or professional values may conflict with options desired by patients, families, employers, and communities. Not infrequently, nurses have to make clinical judgments balancing promoting and safeguarding personal integrity and respecting the values and preferences of patient. The *Essentials* for nursing education includes that nurses need to acknowledge their own personal and professional values, and demonstrate an awareness of their conscious and unconscious biases (AACN, 2021).

Read the scenario below and see if you can articulate what you believe, why you believe this, and how these beliefs are likely to inform the decisions you make and your behavior, especially when you are confronted with competing obligations. Based on Tanner's Clinical Judgment Model (2006), consider reflection-in-action and reflection-on-action (Nielsen et al., 2007):

Reflection-in-Action

As you read, consider what the new nurse is thinking in the moment—what happened? How did the patient and health care team respond? What did the nurse do next?

Scenario

As a new graduate nurse, I was trained in the use of an electronic health record (EHR) and have worked to seamlessly complete my documentation in the moment while I am still in the patient's room. Medication administration now moves pretty quickly and I've learned how to navigate the screens to look up my medications and administer the medications following the general tenets of the rights of medication administration and three checks that were drilled into me while in nursing school. But I admit that I've streamlined the process a bit and rarely think about the actual steps. The triggers and notifications that pop up on the screen are sometimes a nuisance, but I've figured out a way to bypass things that do not seem to apply to my patient. Sometimes I think this system was designed to annoy me while making it impossible to compete straightforward tasks quickly. For example, the last time I entered my patient's vitals in the EHR, something popped up about sepsis, which is ridiculous … my patient does not have a potentially life-threatening infection.

Effective Noticing (Cues)

1. What did you notice about the situation initially? What information/observations are significant? What information deviates from what you have been taught is best practice?

Effective Interpreting

2. How could the information provided in the pop-up be useful? What other assessment data, evidence

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

and/or information would you need to consider in the situation?

3. What do you think about this situation? Does the nurse's clinical judgment ever take precedence over standards of care, protocols, or instruments intentionally included in the EHR? Is this one of those times?

Scenario

On rounds an hour later, the primary provider met with the team and indicated that the patient, admitted with a basic urinary tract infection (UTI) was demonstrating early signs of sepsis. The temperature, respirations, and heart rate were all slightly elevated, which prompted the provider to order a stat blood draw for a lactate, which was also elevated. The team was instructed to initiate the sepsis protocol. Now, consider the nurse's decision to implement shortcuts and reflect on your learning. See if you can articulate what you believe, why you believe this, and how these beliefs are likely to inform the decisions you make and your behavior, especially when you confronted with competing obligations.

Effective Responding

4. How would you describe the obligations you have in this scenario to your patient, to yourself, and to your team? Where do speed and efficiency rank in relation to effective clinical judgment?
5. How did the team approach benefit the patient in this scenario? What if the primary provider had not followed up on the prompt triggered in the EHR by the data you entered?
6. How will you locate the sepsis protocol? Who will you identify to assist you with the implementation of the protocol? What can you delegate and what requires your immediate attention? How will you prioritize your actions?

Effective Reflecting

As you reflect on this case, consider your role and the role of other members of the health care team.

7. Do you need to report that you ignored the trigger in the EHR? Do you think the provider is aware that you did not react? Could this affect your working relationship?
8. What do you really know about the indicators of sepsis? What could be going on behind the scenes in the EHR that prompted this message? What resources can you access to better inform your decision making in the future?
9. What do you know about artificial intelligence, machine learning, and informatics, in general? How do they impact patient outcomes? Are your shortcuts possibly undermining the benefits of integrating machine learning into clinical environments?

Reflection-on-Action

Then look back at the scenario—how might this have been different if the provider had also ignored the message in the EHR? How did your knowledge and/or skills expand based on this scenario? How will you continue to explore informatics and how it can potentially impact on patient outcomes, both positively and negatively? What are the risks and benefits of integrating technology? What attitude, value, or belief shifts did you experience (if any) after reading this scenario? How will you maintain core practice standards once you graduate?

Box 14-5 Tips for NCLEX Success

- If all things are equal in a question, choose the answer that relates to airway, breathing, or circulation (ABC)—focus on the things that are life threatening first.
- If all the data presented in a question are focused on the renal system (for example), look for an answer related to renal function, not any of the other systems.
- If the answers represent unexpected and expected events or data points, the unexpected item is typically the most concerning.
- Mentally enter the patient-care setting described and form an image of the scene to rank-order interventions—walk through the steps of what you would do if you were standing in the described setting.
- If you have enough information in a question to formulate a differential diagnosis, move to an intervention (not assessment) in your answer—in other words, *when in distress, do not assess*.
- Read the question, review all the possible answers, eliminate answers immediately deemed wrong, and

then read the question again—this helps you answer the question you are being asked and forces you to take an extra moment to consider the specific system/priority/strategy/area being tested.
- All cues in a question are important—if age, sex, assessment data, or other elements are included, they are provided to give you situational context that matters when determining the best course of action; when reviewing a chart or other data for a question, watch for patterns and make connections to determine which information is relevant or irrelevant.
- Focus on hallmark presenting signs and symptoms; consider resolution or improvement of these signs and symptoms as a cue that the intervention/treatment/medication has been effective.
- Even if you are not in a program that emphasizes a concept-based curriculum, pay attention to concepts that are related—for example, although very different etiologies, classic (cast-based) compartment syndrome, circumferential burns, cardiac tamponade, and increased intracranial pressure all share core tenets of assessment and intervention.
- When answering a question that a patient asks the nurse (on an NCLEX-style question), answer the patient's question directly and then consider the most therapeutic option.
- Think about what is *reasonable* based on the patient, available resources, your role, and the setting—for example, if the setting is the community, the patient will not have a peripheral intravenous catheter in place for medication administration.
- Only choose to call the provider as the priority answer if you need an intervention that is outside your scope of practice (such as surgery), only once you have enough data to make a reasonable SBAR report, and only when the required intervention is not listed in one of the other answers.

PRACTICING FOR NCLEX

Although the NCLEX-formatted questions included in every chapter will help you solidify your understanding of the content within the chapter, make sure you spend time reviewing the rationale. Learning *why* an answer is wrong is just as important as verifying your answer is correct—test processing is a skill you will need to develop. Also consider the rationale provided for prioritizing. Test processing is not a trick or a game, it is a skill that can be learned. There are several mental schemas that can be used to assist you in choosing the correct answer. Box 14-5 provides a few tips. If your nursing program allows you to return to questions before submitting your exam, never leave an answer blank—mark your initial instinct before moving on to the next question; when you return to review the question, unless you notice something new in the question that you did not catch on the first read or suddenly remember a hallmark or other key element that provides irrefutable rationale, keep your original answer. These five questions are focused on the content from this chapter. Please keep in mind that *all* NCLEX-style questions require clinical judgment. Reflect on your development of content expertise and test processing as you work your way through the NCLEX-style questions at the end of each chapter in this textbook. Review the most recent NCSBN test plan for insight into the types of questions to expect on NGN, including multiple response, hot-spot, drop-down, drag-and-drop, and matrix/grid (NCSBN, 2019b).

. A student nurse walks into a patient room, introduces themselves, and begins to complete a full head-to-toe assessment. The clinical faculty member enters the room, introduces themselves, and asks the student to step out of the room for a moment. The student meets the faculty member in the hallway and is asked to identify 15 cues or observations they noted during their initial contact with the patient and the patient's environment. Although the student is unable to reach 15 observations, the faculty guides the student to recognize the linen on the floor, old dinner tray on the windowsill, empty water pitcher, twisted oxygen tubing, the patient's pallor, and several other things requiring action. What is the value of engaging in this kind of activity with students in the clinical setting?

a. Developing situational awareness is important to risk prevention, timely implementation of interventions, and prioritizing actions
b. Managing cognitive load begins with systematically sorting mental images and immediately addressing pressing concerns
c. Nursing best practice requires that an environmental scan be completed and documented in the electronic health record (EHR)
d. Designing interventions that increase patient satisfaction is an essential focus for nurses when completing their initial assessments

. A nursing program uses Tanner's Clinical Judgment Model, a research-based model that accounts for differences in the patient, environment, and individual student nurse. What makes Tanner's reflection step unique?

a. The emphasis is on noticing, interpreting, and responding; reflection is less important.
b. Reflection occurs both in-action (in the moment) and on-action (after the situation).
c. Reflection occurs first in the model that is focused on rapid decision making and patient outcomes.
d. Reflection is the last step in a linear model and is designed to minimize bias in the student nurse.

. Nursing programs prepare students for safe clinical practice. As a student nurse, why is a basic understanding of NCSBN's Clinical Judgment Measurement Model (CJMM) important? Select all that apply.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

a. Successful completion of the NCLEX is required for professional licensure in the United States.
b. Nurse educators use the CJMM model and NCLEX test plans to develop exam questions.
c. Students should be intimately familiar with theoretical models of education to answer questions.
d. Appreciation of the core principles assists students in understanding the structure and intent of nursing exams.
e. There is overlap in the core components of clinical judgment models, measurement models, and the nursing process.

. Nursing students and those studying other health sciences (medicine, pharmacy, physical therapy, etc.) are often engaged in competency-based education. What is the value of competency-based education?

a. It provides comprehensive skills checklists for students to check their progress and move on to other elements.
b. It allows for student individualization based on their unique experience and preferences.
c. It provides specific guidance on the expected level of performance that integrates knowledge, skills, abilities, and judgment.
d. Like most other education models, it is a high-level way of thinking that is not related to clinical judgment.

. The development of clinical judgment requires intentional focus and a willingness to grow and change both personally and professionally. How can a nursing student best foster the development of clinical judgment?

a. Engaging in learning that only appeals to their preferred learning style
b. Focusing on knowledge acquisition that is straightforward and clear
c. Developing a model for learning that integrates feedback and reflection
d. Focusing inward to develop emotional intelligence and communication skills

ANSWERS WITH RATIONALES

. **a.** The case represents a concrete example of how students develop situational awareness and how that awareness develops with experience. Cognitive load management occurs in many ways; the use of mental images may not facilitate cognitive load management. Although an environmental scan is important, it is generally not documented in the EHR. Patient satisfaction is not the priority when completing the initial assessment; rapport formation, solid assessments, and good patient outcomes are associated with patient satisfaction.

. **b.** Reflection drives the clinical judgment cycle and allows for the integration of new knowledge that will inform future situations. Reflection is as important in Tanner's model as the other elements of noticing, interpreting, and responding. The focus of the model is the development of clinical judgment, rather than rapid decision making; as clinical judgment is developed, decision making improves and may lead to better patient outcomes. Tanner's model is cyclic, not linear; although bias may be addressed as part of the development of clinical judgment, it is not the focus.

. **a, b, d, e.** Nurses in the United States must pass NCLEX prior to being issued a license to practice as a professional nurse. To help students achieve this goal, nurse educators model course exams on the NCSBN's NCLEX test plan in terms of content and style. Understanding the *why (rationale for actions)* is often helpful when students are engaged in studying, working to apply the information they have learned, and developing test-taking strategies. There is overlap between the models and processes identified as foundational to nursing education, which demonstrates the importance of fundamental concepts. A deep understanding of theoretical and philosophical models is not necessary for student nurses.

. **c.** The definition of a competency included in the *Nursing: Scope and Standards of Practice* (ANA, 2021) identified includes knowledge, skills, abilities, and judgment. Competency-based education is more than a checklist and often requires repeated exposure to concepts for mastery in a variety of contexts. Although the delivery of education can flex to meet the needs of students, testing is standardized to address core competencies. Competency-based education is very direct and concrete; the development of competence requires clinical judgment.

. **c.** Each nursing student is in charge of their learning, including integrating feedback from exams, clinical experiences, simulations, and other assignments—reflecting on what has been learned and integrating new learning. Adaptability is key. Classroom and clinical learning presents information in myriad ways and in different settings. Students should learn what they can from each situation and adapt their studying style as needed. Nursing knowledge, like patient care, is rarely straightforward and clear. Picking up on cues, emphasizing the correct element, answering the question being asked, and maintaining a person-centered focus that is individualized and nuanced requires practice and time. Students must give themselves the space and grace needed to learn and apply information in various situations. There is a reciprocity in learning that requires and inward and outward combination. Engagement with others and the environment is essential for shaping thinking and development of clinical judgment.

Assessing

Susan Morgan

Susan is a 34-year-old woman newly diagnosed with multiple sclerosis (MS). She says, “How am I going to tell my husband? We were just married last year and planned to do lots of hiking and outdoor sports. It’s not fair for him to be tied down to me if I can’t be the wife and partner that he thought he had married.”

Sylvia Wu

Sylvia, a 17-year-old adolescent, has just arrived back in the United States after a visit to her family in mainland China. She comes to the emergency department because she woke up that morning with flulike symptoms (cough, sore throat, fever, muscle aches, fatigue). “I’m scared because of everything I’ve seen on television and read in the newspapers about that new virus.”

James Farren

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

James is a college junior who comes to the student health center complaining of difficulty sleeping, eating, and studying. He reveals that his mother died when he was 8 years old, and last semester his father died suddenly in a car crash. “Ever since my dad died, nothing seems to mean anything anymore. All I see is gray.”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Define and describe the purpose of six types of nursing assessments.
. Explain the relationship between nursing assessment and medical assessment.
. Differentiate between objective and subjective data.
. Identify five sources of patient data useful to the nurse.
. Describe the purpose of nursing observation, interview, and physical assessment.
. Obtain a nursing history using effective interviewing techniques.
. Plan patient assessments by identifying assessment priorities and structuring the data to be collected systematically.
. Identify common problems encountered in data collection, noting their possible causes.
. Explain when data need to be validated and several ways to accomplish this.
. Describe privacy, confidentiality, and professionalism issues related to patient assessment and data storage.
. Describe the importance of knowing when to report significant patient data and of proper documentation.
. Obtain and document purposeful, prioritized, complete, systematic, accurate, and relevant patient data in a standard format.

A**ssessing** is the systematic and continuous collection, analysis, validation, and communication of patient **data**, or information. These data reflect how health functioning is enhanced by health promotion or compromised by illness and injury. A **database** includes all the pertinent patient information collected by the nurse and other health care professionals. The database enables you to partner with patients to develop a comprehensive and effective care plan. Assessment, the first phase of the nursing process, is the first of six American Nurses Association (ANA) Standards of Practice: The registered nurse collects pertinent data and information relative to the healthcare consumer's health or the situation (ANA, 2021). Be sure to visit the website to read each of the competencies in this standard. Collecting patient data is a vital step in the nursing process because the remaining steps depend on purposeful, prioritized, complete, systematic, accurate, and relevant data. Assessment is critical for safety, accuracy, and efficiency (Alfaro-LeFevre, 2014, p. 46).

Refer to the Reflective Practice box regarding **Sylvia Wu**, a patient who fears that she has a virus. The nurse's assessment would reveal possible risk factors. In addition, the patient's statements about her fears provide further data on which to develop a care plan.

The initial comprehensive nursing assessment results in baseline data that enable the nurse to:

- make a judgment about a person's health status, ability to manage their own need for self-care, and the need for nursing care.
- plan and deliver thoughtful, person-centered nursing care that draws on the person's strengths and promotes optimum functioning, independence, and well-being.
- refer the patient to a provider or other health care professional, if indicated.

In addition to an initial assessment of the patient, the nurse makes ongoing assessments. These assessments alert the nurse to changes in the patient's responses to health and illness and suggest necessary changes in the plan of nursing care or care offered by other health care professionals.

During the assessment step of the nursing process, the nurse establishes the database by interviewing the patient to obtain a **nursing history**. The nursing history identifies the patient's health status, strengths, actual and potential health problems, health risks, and need for nursing care. The nurse may also perform a nursing physical examination to collect data. Other sources of patient information used by the nurse include the patient's family and significant others, the patient record, other health care professionals, and nursing and other health care literature.

After the nurse has established the database, data about the patient are collected continuously because the patient's health status can change quickly. Questionable data are verified (validated) as part of the assessment step of the nursing process. All pertinent data are recorded and communicated to other health care professionals so that the data can best benefit the patient (Fig. 15-1 on page 406). In addition to collecting data, nurses might use intuition to assess patients (see Chapter 13).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

UNIQUE FOCUS OF NURSING ASSESSMENT

When nurses make nursing assessments, they do not duplicate medical assessments. Medical assessments target data pointing to pathologic conditions, whereas nursing assessments focus on the patient's responses to health problems. For example, is there interference with the patient's ability to meet basic human needs? Can the patient perform the activities of daily living? Although the findings from a nursing assessment may contribute to the identification of a medical diagnosis, the unique focus of nursing assessments is on the patient's responses to actual or potential health problems and needs.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO INTELLECTUAL SKILLS

While on a clinical rotation in the emergency department, I met Sylvia Wu, a 17-year-old adolescent who had just arrived back in the United States after a visit to her family in mainland China. She came to the emergency department because she woke up that morning with flulike symptoms (cough, sore throat, fever, muscle aches, fatigue) and was terrified because of everything she had seen on television and read in the newspapers about the latest virus. Of the 64 people who have died already, she knows that most of the cases are in Asia. She came to the emergency department begging to be told that she doesn't have the virus but just fatigue or a cold. I want to calm her, but I honestly don't know what she has. Besides, I am starting to feel a bit anxious myself because the one thing everyone knows about this virus is the fact that it is extremely "contagious." I could feel myself recoil when Sylvia sneezed.

Thinking Outside the Box: Possible Courses of Action

- Reassure Sylvia and tell her not to worry because the overwhelming probability is that her symptoms aren't anything serious.
- Quickly get someone with more experience to care for Sylvia because I don't want to be anywhere near her if she does have this virus.
- Document and report her concerns, trying to keep her isolated and away from other patients, while trying to find more information about this new virus quickly, since I'm not sure about its signs and symptoms.

Evaluating a Good Outcome: How Do I Define Success?

- Sylvia gets the medical treatment she needs, and her fears are appropriately addressed.
- In the event that Sylvia does have a highly communicable disease, the risk for disease transmission to others is reduced.
- I manage to control my fears, being able to respond to Sylvia's concerns appropriately.
- I learn something about my immediate response to feeling at risk and my commitment to professionalism.

Personal Learning: Here's to the Future!

Although I am not proud of my response, I falsely reassured Sylvia that this was probably nothing. As a result, I did not report or document her fears. Unfortunately, Sylvia was diagnosed with the virus, and several others in our emergency department at that time became infected. For some reason, I escaped. In the future, I hope I'll never be so insensitive to a patient's concerns or insights again.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? What factors might have influenced this nursing student's actions? What types of data could have led the nursing student to a different course of action? How might the nursing student have assessed the patient differently? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Wu?

Patient-Centered Care: How would you develop a partnership with Ms. Wu, knowing her fears? If steps are needed to keep others safe, how can you communicate to Ms. Wu that she is your care priority?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to improve

to ensure that you function as a member of the patient care team and to obtain assistance when needed? How might the transmission of this infection have been prevented?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" in situations like this to keep everyone safe and to treat Ms. Wu effectively? Are you familiar with the latest Centers for Disease Control and Prevention (CDC) guidelines for isolation precautions?

Informatics: Can you identify the essential information that must be available in Ms. Wu's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

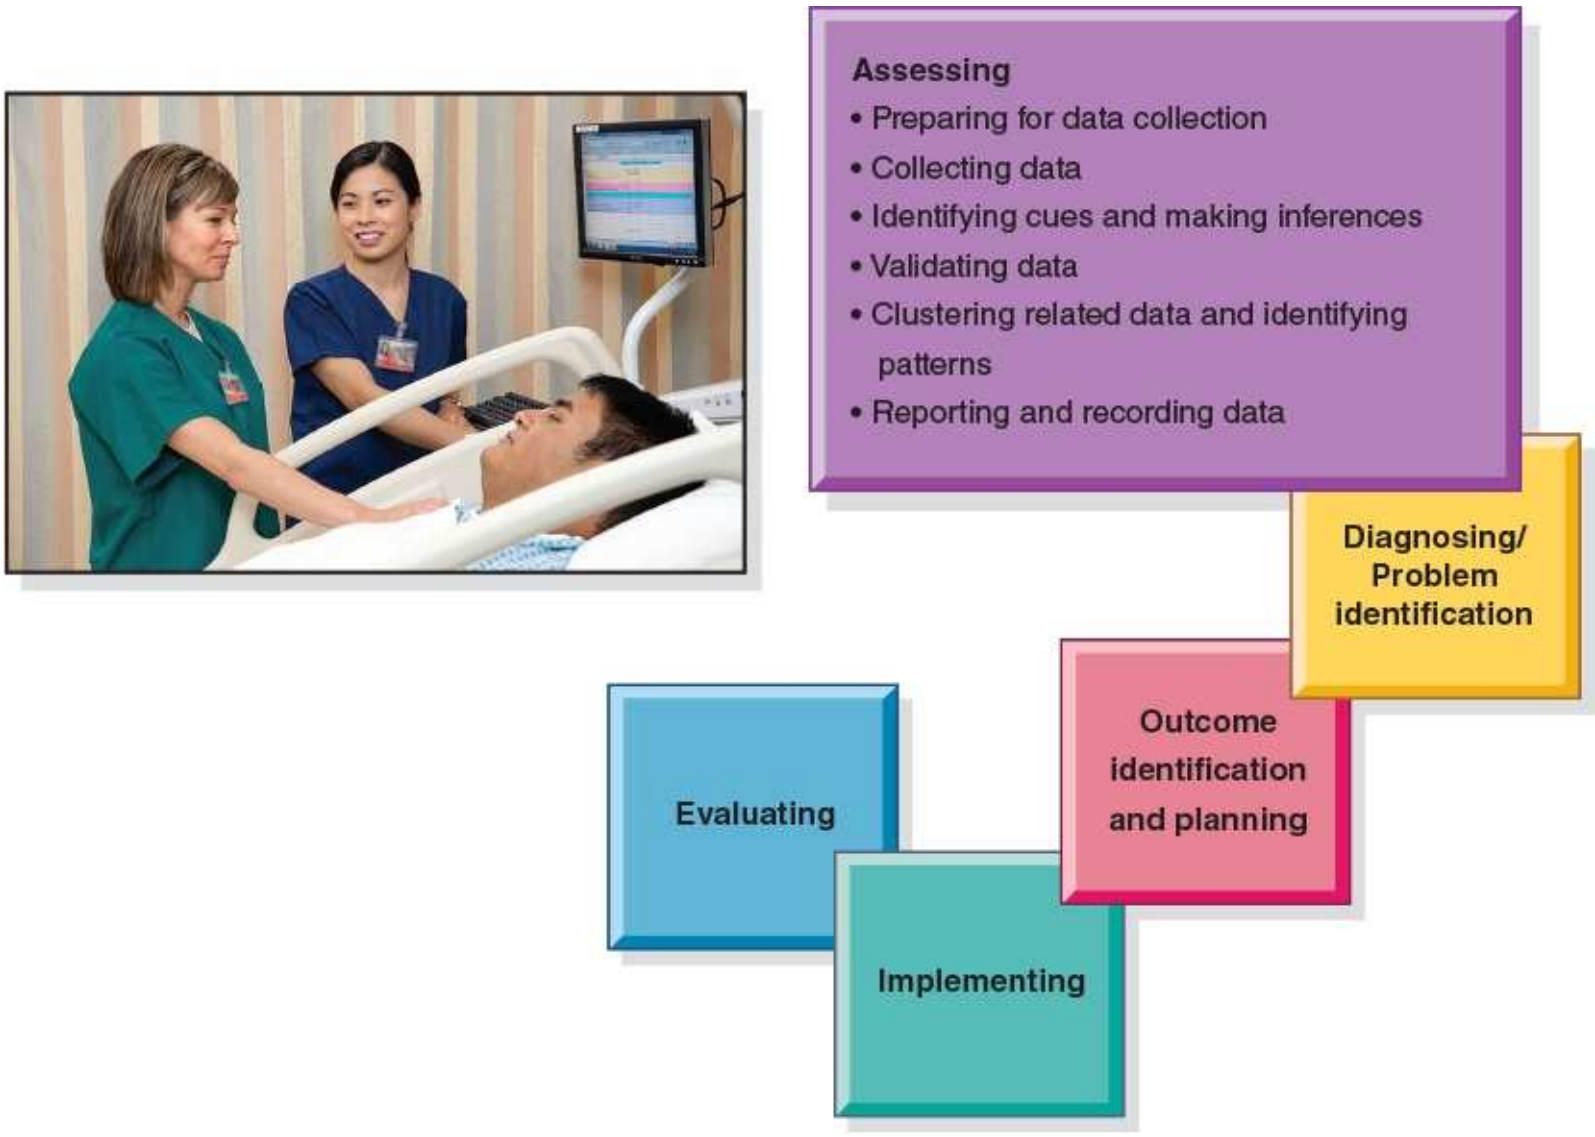

FIGURE 15-1. Assessing. The primary source of patient information is the patient. Other resources include the patient's support people, the patient record, information from other health care professionals, and information from nursing and health care literature.

Remember **Susan Morgan**, a patient recently diagnosed with MS? By looking at the data supplied by the patient, the nurse would be able to determine that the patient's new diagnosis of MS is affecting her body image and self-esteem. The nurse then would use this information to focus assessment questions to obtain additional information to be included in the database, from which a care plan specific to Susan's needs can be developed.

ASSESSMENT, CLINICAL REASONING, AND CLINICAL JUDGMENT

Since the entire nursing process rests on the initial and ongoing assessment of the patient, it is imperative to use excellent critical thinking and clinical reasoning and judgment skills when gathering, analyzing, validating, and communicating data. According to Alfaro-LeFevre (2010, p. 49), among the critical thinking activities linked to assessment are:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assessing systematically and comprehensively, using a nursing framework to identify nursing concerns and a body systems framework to identify medical concerns
- Detecting bias and determining the credibility of information sources
- Distinguishing normal from abnormal findings and identifying the risks for abnormal findings
- Making judgments about the significance of data, distinguishing relevant from irrelevant
- Identifying assumptions and inconsistencies, checking accuracy and reliability, and recognizing missing information

To promote sound clinical reasoning and judgment, your nursing assessments should be:

Purposeful. When preparing for data collection, identify the purpose of the nursing assessment (comprehensive, focused, emergency, time-lapsed) and then gather the appropriate data. The circumstances of the patient's situation may also dictate the nature and amount of data you collect.

Prioritized. It is essential to get the most important information first. We address how to do this later in this chapter.

Complete. As much as possible, identify all the patient data needed to understand a patient health problem and develop a care plan to maximize the patient's health and well-being. For example, knowing that a patient has lost weight is not fully meaningful until you discover (1) if the weight loss was intentional or unintentional, (2) if it was related to a change in eating or exercise patterns or to some underlying pathologic condition, and (3) how the patient views and is responding to the weight loss.

Systematic. Using a systematic way to gather data, you will always know if you've missed something important.

Factual and accurate. Both you and the patient, as well as family members and other caregivers, may intentionally or unintentionally misrepresent or distort patient information. For example, a patient who values being thin may describe a weight gain of several pounds as the onset of obesity. If you are concerned with accuracy and factual reality, you will continually verify what you hear with what you observe, using other senses and validating all questionable data. At the outset of data collection, it is crucial that you determine whether the patient or caregiver who is supplying the data is reliable. If you suspect that your own personal bias or stereotyping may be influencing your data collection, you should consult with another nurse. You should also describe observed behavior rather than interpreting the behavior. For example: "Patient frequently is observed lying with his face to the wall. Attempts to engage him in conversation fail. He refused lunch today and ate only soup for dinner." In contrast, the statement "Patient is depressed" is an interpretation of the patient's behavior, not a factual statement. Recording the patient's behaviors factually allows other health care professionals to explore causes of the behavior with the patient.

Relevant. Because recording comprehensive data can be very time consuming, one challenge facing you as a nurse is to determine what types of and how much data to collect for each patient. As described throughout this chapter, the aim is to record concisely all pertinent data. Often, only experience will teach you what data are needed in specific cases.

Recorded in a standard manner. Data cannot be efficiently used unless you record the information according to the facility's policy so that all caregivers can easily access what you learned.

Learning how to collect, validate, and communicate data that are purposeful, prioritized, complete, systematic, accurate, and relevant is the focus of the remainder of this chapter. Many assessment activities are challenging for those new to nursing, who often lack the types of clinical experiences that facilitate expert clinical reasoning. Thus, students are urged to ask questions frequently about data and to test their inferences and judgments.

ASSESSMENT AND INTERPERSONAL COMPETENCE

The nurse's interpersonal competence is critical beginning with the very first assessment by the nurse. The patient's initial impression of the nurse is crucial, especially with patients who are new to the health care environment or who have had bad experiences. *The patient may judge all nurses encountered in the future in light of this first impression.* When the nurse communicates respect and genuine concern for the patient, the patient is encouraged to discuss health concerns and problems freely. The nurse's competence and professionalism, as well as the interpersonal qualities of being respectful and caring, invite the patient's confidence and assure the patient that help is available. Successful assessments begin with the trust and confidence an interpersonally competent nurse inspires. See the Guidelines for Nursing Care: Promoting a Caring Interview 15-1 on page 420.

Alfaro-LeFevre (2014, p. 66) recommends avoiding these communication errors:

- Using first names without permission, which is disrespectful
- Using honey, dear, sweetie, pop, or grandma
- "Talking down" (e.g., "so you have a pain in your tummy?")
- Using medical terminology with lay people
- Ignoring patients' nonverbal communication

TYPES OF NURSING ASSESSMENTS

Traditional nursing assessments include the comprehensive initial assessment, the focused assessment, the emergency assessment, quick priority assessments, triage assessments, and the time-lapsed assessment. This chapter focuses on assessing the health status of an individual patient, but as you develop expertise in nursing assessments you will also be able to assess communities and special populations, such as schoolchildren, members of the LGBTQIA+ communities, the homeless, and people with infectious diseases.

Initial Assessment

The **initial assessment** is performed shortly after the patient is admitted to a health care facility or service. Most institutions have policies specifying the time interval within which this assessment must be completed. The purpose of this assessment is to establish a complete database for problem identification and care planning. The nurse collects data concerning all aspects of the patient's health, establishing priorities for ongoing focused assessments and creating a reference baseline for future comparison. See Figure 15-2 (on page 408) for a sample of an initial assessment in an electronic medical record. For an example of a handwritten admission database, see Figure 15-3 (on pages 409–410).

Focused Assessment

In a **focused assessment**, the nurse gathers data about a specific problem that has already been identified. Helpful questions include:

- What are your signs and symptoms?
- When did they start?
- Were you doing anything different than usual when they started?
- What makes your symptoms better? Worse?
- Are you taking any remedies (medical or natural) for your symptoms?

A focused assessment may be done during the initial assessment if the patient's health problems surface, but it is routinely part of ongoing data collection. Another purpose of the focused assessment is to identify new or overlooked problems. Each of the clinical chapters in this text offers focused assessment guides describing factors to assess and related questions and approaches for common problems.

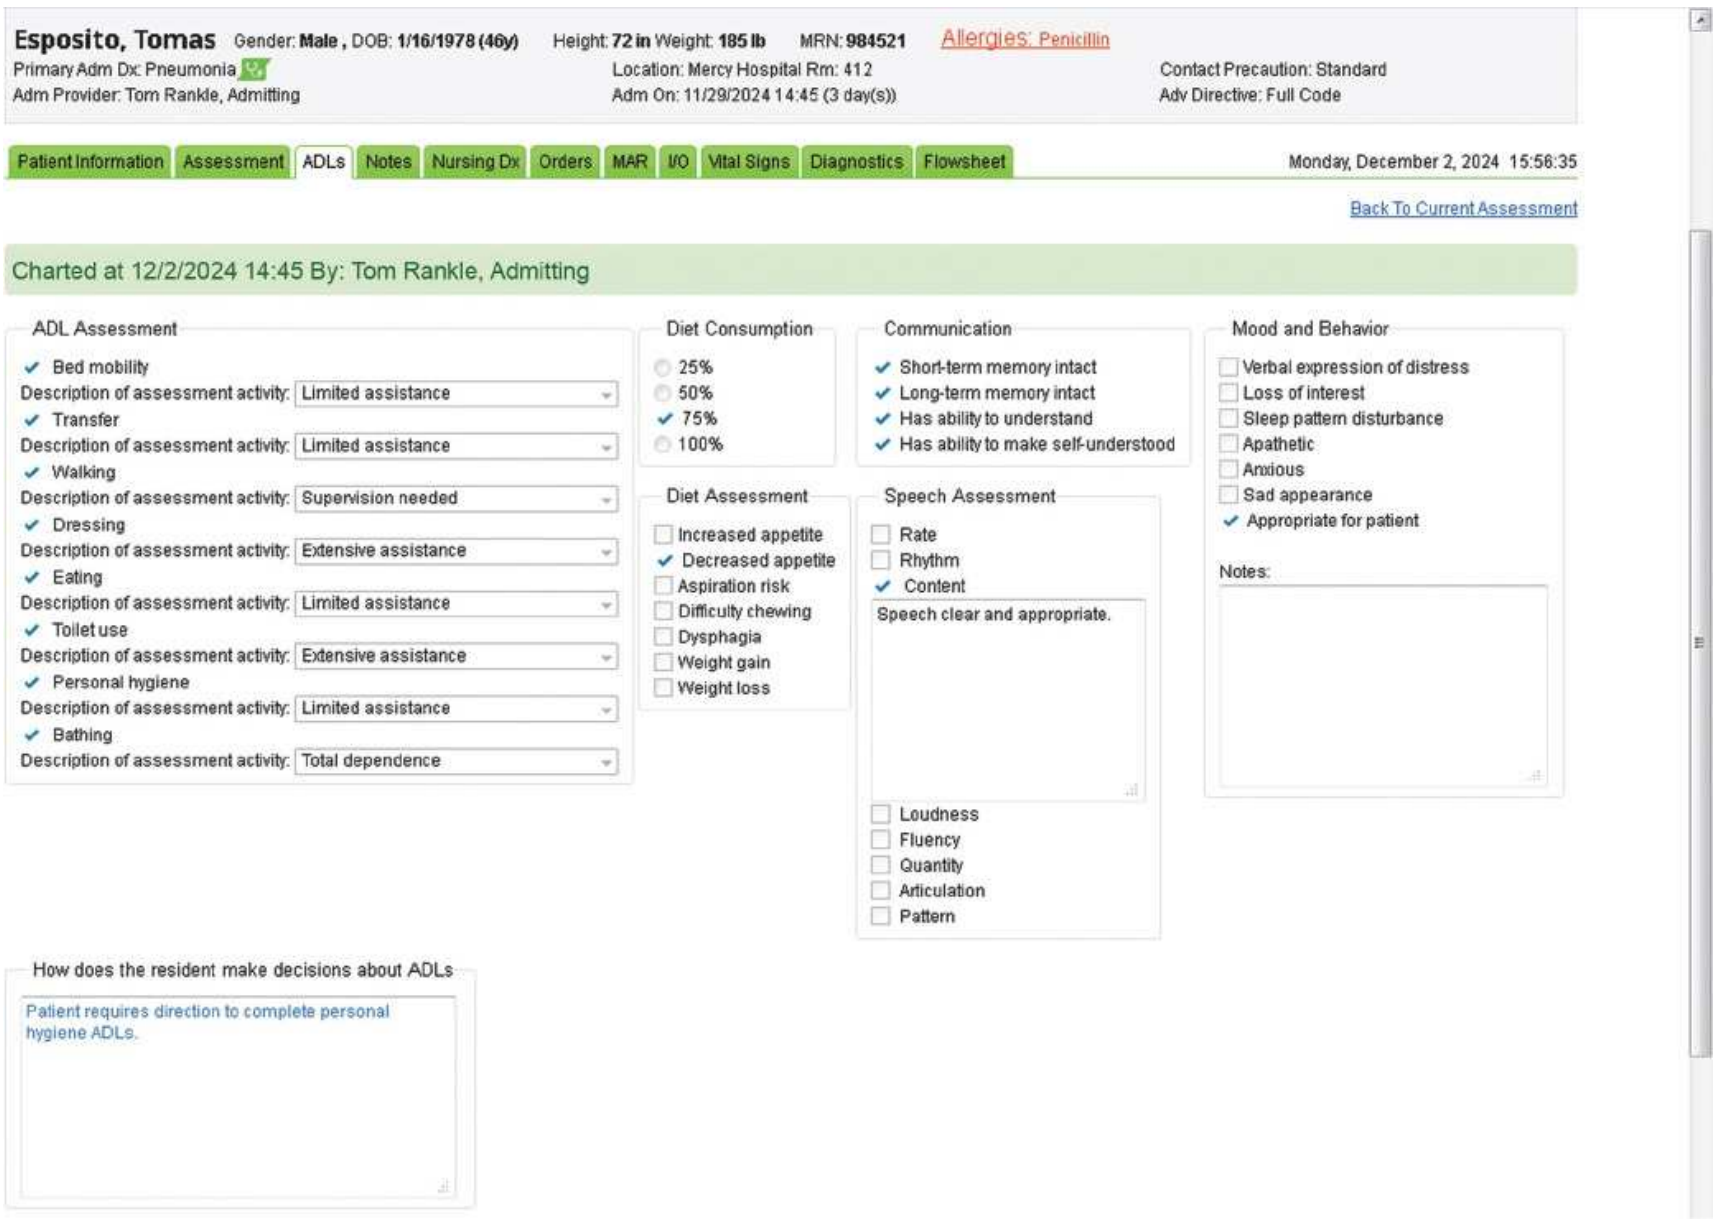

FIGURE 15-2. Section of sample electronic nursing admission assessment form. (Used with permission. Fictitious data.)

Quick Priority Assessments

Quick priority assessments (QPAs) are short, focused, prioritized assessments you do to gain the most important information you need to have first. They are important because they can "flag" existing problems and risks (Alfaro-LeFevre, 2014, p. 50).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Sylvia Wu**, the 17-year-old who comes to the emergency department because she thinks that she might have a virus. The nurse would use a focused assessment to evaluate her complaints that relate specifically to her respiratory status. If the nurse suspects a communicable disease, they would also need to consider what precautions to take before continuing with the assessment. This information would be supplemented by additional data about the patient's recent travel to mainland China.

Emergency Assessment

When a patient presents with a physiologic or psychological crisis, the nurse performs an **emergency assessment** to identify life-threatening problems. A long-term care facility resident who begins choking in the dining room, a bleeding patient brought to the emergency department with a stab wound, an unresponsive patient in the rehabilitation unit, and a factory worker threatening violence are all candidates for an emergency assessment. In the first example, the source of the choking is assessed; in the second, the blood loss and wound characteristics; in the third, airway, breathing, and circulation; and in the fourth, the potential for immediate harm.

Time-Lapsed Assessment

The **time-lapsed assessment** is scheduled to compare a patient's current status to the baseline data obtained earlier. Most patients in residential settings and those receiving nursing care over longer periods of time, such as homebound patients with visiting nurses, are scheduled for periodic time-lapsed assessments to reassess their health status and to make necessary revisions in the care plan. This assessment can be comprehensive or focused.

Triage Assessment

Many nurses serve as **triage** professionals who screen patients to determine the extent and severity of the their problems and then recommend appropriate follow-up. A triage nurse working for an internal medicine practice in a university hospital will take phone calls from patients without appointments experiencing distressing symptoms such as shortness of breath, pressure or tightness in the chest, or increases in temperature. The importance of triage nurses during the COVID-19 pandemic was quickly apparent. The Oncology Nursing Society (2020) offered special guidance to their telephone triage nurses, citing the fear and uncertainties persons with cancer were experiencing about coming for their regular clinic appointments, knowing they were at higher risk of acquiring COVID-19. Triage nurses fielding phone calls were instructed to (1) assess the need for an in-person appointment, (2) assess risk of developing serious complications from COVID-19, (3) assess for symptoms of COVID-19, and (4) educate on risk reduction

(https://voice.ons.org/news-and-views/covid-19-telephone-triage-for-patients-with-cancer).

Triage nurses need highly specialized nursing knowledge and clinical reasoning and judgment skills since the life and well-being of their patients are literally in their hands.

Patient-Centered Assessment Method

The **Patient-Centered Assessment Method (PCAM)** is a tool health care practitioners can use to assess patient complexity using the social determinants of health (see Chapter 3); these determinants may explain why some patients engage and respond well in managing their health while others with the same or similar health conditions do not experience the same outcomes. The PCAM assessment tool helps you ask questions to gain understanding about the patient's:

- health and well-being—lifestyle behaviors, impact of physical health on mental health, ability to enjoy daily activities
- social environment—status of employment, housing, transportation, and social networks
- health literacy and communication skills—understanding of symptoms and risk factors, language and cultural differences, learning difficulties

Questions about these health determinants may help you discover other factors that are affecting the person's ability to manage their health.

The PCAM method recognizes that patient response to health issues may be related to multiple chronic medical conditions as well as social and environmental factors, and it is very likely a combination of both. Factors that interfere with a patient's usual care and decision making can make providing health care more difficult and complex, and can affect the patient's health and recovery. If you are committed to learning about these factors and addressing them as part of your patients' medical care, you can have a positive effect on their health and improve your partnership with patients and their families.

The PCAM assessment tool (Fig. 15-4 on pages 412–413) is action oriented, with the final section focused on the actions that can be taken to address the needs and issues identified in the assessment. The tool is available at https://med.umn.edu/familymedicine/research/faculty-research/pcam. Other helpful online tools to assess patient assets and risks, in light of what we know about the social determinants of health, are available from the CDC and the National Association of Community Health Centers (NACHC):

Ten Essential Public Health Services and How They Can Include Addressing Social Determinants of Health Inequities, retrieved from https://www.cdc.gov/stltpublichealth/publichealthservices/pdf/ten_essential_services_and_sdoh.pdf

PRAPARE: Protocol for Responding to and Assessing Patient Assets, Risks, and Experiences, retrieved from http://www.nachc.org/wp-content/uploads/2016/09/PRAPARE_One_Pager_Sept_2016.pdf

PREPARING FOR DATA COLLECTION

Establishing assessment priorities and systematically structuring data collection are two important considerations when preparing for data collection.

Establishing Assessment Priorities

Before beginning to collect data on any patient, think carefully about the type of data needed to develop a satisfactory care plan. This also includes identifying data of a lower priority that you should not repeatedly collect. For example, data already collected from the patient and in the patient record should not be repeatedly sought unless there is a need for validation. Repetitious questioning can be annoying to a patient and may cause the patient to wonder about a lack of communication among health care professionals. A careful review of the patient record before interviewing the patient helps prevent this problem.

Nurses spend more or less time on different assessment components depending on the patient's reason for needing nursing care.

QSEN PATIENT-CENTERED CARE

Pediatric nurses are careful to establish the developmental age and milestones obtained by children admitted to a pediatric unit so that they can respect and promote the child's achievements. A school nurse who suspects child abuse pays careful attention to the child's statements about living conditions at home and relationships with family members and caregivers. A nurse preparing to discharge a patient from same-day surgery makes sure that the patient has the human and physical resources needed for appropriate postoperative care.

The purpose for which the assessment is being performed offers the best guidance for what type and how much data

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

to collect. Assessment priorities are influenced by the patient's health orientation, developmental stage, culture, and need for nursing. Following the comprehensive nursing assessment, the patient's health problems dictate assessment priorities for future nurse–patient interactions.

Patient Centered Assessment Method (PCAM)

ID _____ Date: __ __/ __ __ __/2 0 __ __

Nurse/Clinician:

Instructions: Use this assessment as a guide, ask questions in your own words during the consultation to help you answer each question. Circle one option in each section to reflect the level of complexity relating to this patient. To be completed either during or after the consultation.

Health and Well-being			
1.	Thinking about your patient's **physical health needs**, are there any symptoms or problems (risk indicators) you are unsure about that require further **investigation**?		
No identified areas of uncertainty or problems already being investigated	Mild vague physical symptoms or problems; but do not impact on daily life or are not of concern to patient	Mod to severe symptoms or problems that impact on daily life	Severe symptoms or problems that cause significant impact on daily life
2.	Are the patient's **physical health problems** impacting on their **mental well-being**?		
No identified areas of concern	Mild impact on mental well-being, e.g., "feeling fed-up," "reduced enjoyment"	Mod to severe impact upon mental well-being and preventing enjoyment of usual activities	Severe impact upon mental well-being and preventing engagement with usual activities
3.	Are there any problems with your patient's **lifestyle behaviors** (alcohol, drugs, diet, exercise) that are impacting on **physical** or **mental well-being**?		
No identified areas of concern	Some mild concern of potential negative impact on well-being	Mod to severe impact on patient's well-being, preventing enjoyment of usual activities	Severe impact on patient's well-being with additional potential impact on others
4.	Do you have any **other concerns** about your patient's **mental well-being**? How would you rate their severity and impact on the patient?		
No identified areas of concern	Mild problems—don't interfere with function	Mod to severe problems that interfere with function	Severe problems impairing most daily functions
Social Environment			
1.	How would you rate their **home environment** in terms of **safety and stability** (including domestic violence, insecure housing, neighbor harassment)?		
Consistently safe, supportive, stable, no identified problems	Safe, stable, but with some inconsistency	Safety/stability questionable	Unsafe and unstable
2.	How do **daily activities** impact on the patient's well-being? (include current or anticipated unemployment, work, caregiving, access to transportation or other)		
No identified problems or perceived positive benefits	Some general dissatisfaction but no concern	Contributes to low mood or stress at times	Severe impact on poor mental well-being
3.	How would you rate their **social network** (family, work, friends)?		
Good participation with social networks	Adequate participation with social networks	Restricted participation with some degree of social isolation	Little participation, lonely and socially isolated

Health Orientation

Nurses may use health assessments, such as the Health-Style Self-Test in Chapter 3 and the Promoting Health displays in each clinical chapter, to help patients identify potential and actual health risks and to explore the habits, behaviors, beliefs, attitudes, and values that influence their wellness. The literature abounds in specialized assessment tools that focus on relationships; psychological, environmental, and physical self-care; relaxation; spirituality; humor and play; movement and exercise; sleep and dreams; nutrition; and sexuality. These assessments generally gather a different type of patient data compared to the assessments of patients being treated for disease-related treatment.

Developmental Stage

Nursing assessments vary according to the patient's developmental needs. For example, when assessing an infant, special attention is given to weight gain and physical growth, feeding and elimination problems, sleep–activity cycles, and the parenting skills of caregivers. When a child is hospitalized, it is important to note how independent the child is with basic care measures (toileting, hygiene, dressing, eating), what words the child uses to indicate the need to void and defecate, play preferences, and so on.

Culture

When assessing patients, remember the influence of cultural factors such as race, ethnicity, religious beliefs, and socioeconomic factors. Consideration of the patient's culture begins with how you approach the patient and whether or not you make direct eye contact or shake the person's hand. Chapter 5 offers practical guidelines for incorporating cultural considerations into nursing assessments. Also assess the need for an interpreter. In what language does the patient wish to communicate? If an interpreter is necessary, be sure to follow your facility's policy about using a professional interpreter, since it is inappropriate to rely on the patient's family members for this service.

Need for Nursing

The likely duration of the nurse's interaction with the patient (e.g., same-day surgery vs. surgery requiring a long recovery in an intensive care unit) and the nature of nursing care needed by the patient (e.g., assistance with the birth of a baby vs. support and home care throughout a terminal illness) are both factors that powerfully influence the type of data the nurse collects. A general assessment guideline is to gather only data that are helpful when planning and delivering care. It would be inappropriate, for example, to collect a detailed sexual history of a patient admitted to the hospital overnight after a slight concussion. Conversely, if your patient is a pregnant woman admitted to the hospital for observation because of bleeding during their first trimester, you should not fail to ask whether they has any questions about resuming sexual activity after returning home.

Think back to **James Farren**, the college junior described at the beginning of the chapter. The nurse would assess his sleeping, eating, and activity habits as well as his emotional status to gain further insight into his possible problems. However, a detailed assessment of his elimination habits would probably be inappropriate at the present time.

Structuring the Assessment

Because many different types of data are collected about patients, data collection must be structured systematically. Systematic guidelines specifically developed for a nursing assessment help ensure that comprehensive, holistic data are collected for each patient and lead easily to formulating nursing diagnoses. When the nurse internalizes such assessment guidelines, it is easier to focus on the patient during the assessment rather than worrying about what to assess next.

Most schools of nursing and health care institutions have a **minimum data set** that specifies the information that must be collected from every patient and uses a structured assessment form to organize or cluster this data. Many nursing assessment guides are based on holistic models rather than medical models. Gordon's (1994) framework identifies 11 functional health patterns and organizes patient data within these patterns. Maslow's hierarchy of five levels of human needs may also be used to organize data. A medical model often organizes data collection according to body systems. Although the medical model is helpful for formulating diagnoses related to physiologic problems, it neglects patient problems and strengths in psychosocial and spiritual dimensions of health and well-being.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Some students use the HELP mnemonic shown in Box 15-1 to ensure systematic person-centered observation.

Whichever approach you use for structuring your nursing assessment, always conclude by asking the patient if there is anything else they would like you to know so that you will be better able to provide care. This allows the patient to address anything critical that you may have missed.

Table 15-1 describes models for organizing assessment data.

COLLECTING DATA

There are two types of data: subjective and objective. **Subjective data** are information perceived only by the affected person; these data cannot be perceived or verified by another person. Examples of subjective data are feeling nervous, nauseated, or chilly, and experiencing pain. Subjective data also are called symptoms or covert data.

Objective data are observable and measurable data that can be seen, heard, felt, or measured by someone other than the person experiencing them. Objective data observed by one person can be verified by another person observing the same patient. Examples of objective data are an elevated temperature reading (e.g., 101°F), skin that is moist, and refusal to look at or eat food. Objective data also are called signs or overt data. Table 15-2 (on page 416) compares subjective and objective data.

Box 15-1 HELP Mnemonic for Patient Observation

Help: Observe the first signs patient may need help. Look for signs of distress (pallor, pain, labored breathing).

Environmental equipment: Look for safety hazards; ensure that all equipment is working (IVs, oxygen, catheter).

Look: Examine the patient thoroughly.

People: Who are the people in the room? What are they doing?

Table 15-1 Models for Organizing or Clustering Data

HOLISTIC			MEDICAL
Human Needs (Maslow)	**Functional Health Patterns (Gordon)**	**Human Response Patterns (Unitary Person)**	**Body System Model**
Physiologic (Survival) Needs: Food, fluids, oxygen, elimination, warmth, physical comfort *Safety and Security Needs:* Things necessary for physical safety (e.g., a cane) and psychological security (e.g., a child's favorite toy) *Love and Belonging Needs:* Family and significant others *Self-Esteem Needs:* Things that make people feel good about themselves and confident in their abilities (e.g., being well groomed, having accomplishments recognized) *Self-Actualization Needs:* Need to grow, change, and accomplish goals	*Health Perception/Health Management:* Perception of general health status and well-being; adherence to preventive health practices *Nutritional–Metabolic:* Patterns of food and fluid intake, fluid and electrolyte balance, general ability to heal *Elimination:* Patterns of excretory function (bowel, bladder, skin) and patient's perception *Activity/Exercise:* Pattern of exercise, activity, leisure, recreation, and ADLs; factors that interfere with desired to expected individual pattern *Cognitive–Perceptual:* Adequacy of sensory modes such as vision,	*Exchanging:* Nutritional status, temperature, elimination, oxygenation, circulation, fluid balance, skin, and mucous membranes, risk for injury *Communicating:* Ability to express thoughts verbally; orientation, speech impairments, language barriers *Relating:* Establishing bonds, social interaction, support systems, role performance (including parenting, occupation, and sexual role) *Valuing:* Religious and cultural preference and practices, relationship with deity, perception of suffering; acceptance of illness *Choosing:* Ability to accept help and make decisions, adjustment to health status, desire for independence/dependence, denial of problem, adherence to therapies	Neurologic Cardiovascular Respiratory Gastrointestinal Musculoskeletal Genitourinary Psychosocial

hearing, taste, touch, smell, pain perception, cognitive functional abilities	*Moving:* Activity tolerance, ability for self-care, sleep patterns, diversional activities, disability history, safety needs, breastfeeding
Sleep/Rest: Patterns of sleep and rest–relaxation periods during a 24-hour day, as well as quality and quantity	*Perceiving:* Body image, self-esteem, ability to use all five senses, amount of hopefulness, perception of ability to control current situation
Self-Perception/Self-Concept: Attitudes about self, perception of abilities, body image, identity, general sense of worth, and emotional patterns	*Knowing:* Knowledge about current illness or therapies; previous illnesses; risk factors, expectations of therapy, cognitive abilities; readiness to learn, orientation, memory
Role/Relationship: Perception of major roles and responsibilities in current life situation	*Feeling:* Pain, grieving, risk for violence, anxiety level, emotional integrity
Sexuality and Reproductive: Perceived satisfaction or dissatisfaction with sexuality, reproductive state, and pattern	
Coping/Stress Tolerance: General coping pattern, stress tolerance, support systems, perceived ability to control and manage situations	
Value Belief: Values, goals, or beliefs that guide choices or decisions	

Source: Data from Alfaro-LeFevre, R. (2014). *Applying nursing process. The foundation for clinical reasoning* (8th ed.). Wolters Kluwer Health/Lippincott Williams & Wilkins.

Paying attention to both subjective and objective data promotes clinical reasoning and judgment because often the two types of data complement and clarify one another. Many providers were taught to use the OLD CARTS mnemonic to structure their assessment of patient symptoms:

- **O**nset: When did your symptom(s) begin?
- **L**ocation: Where is the symptom?
- **D**uration: Is it episodic? How long does it last?
- **C**haracteristics: How would you describe it?
- **A**lleviating and **A**ggravating factors: What makes it worse?
- **R**elieving factors: What makes it better?
- **T**reatments: Have you tried anything to make it better?
- **S**everity: On a scale of 1–10, with 1 being the lower number, how serious is the symptom?

Table 15-2 Comparison of Objective and Subjective Data

OBJECTIVE DATA	SUBJECTIVE DATA
32-year-old man Height: 5′8″	“I’m beginning to feel better about myself now that I’m losing weight and I seem to have more

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Weight: 9/18/24—224 lb 2/4/24—202 lb	energy.”
Posterior, left midcalf is warm and red.	“My leg hurts when I walk.”
Patient observed fidgeting with bed covers; facial features are tightly drawn.	“I’m so afraid of what they might find when they cut me open tomorrow.”

Review the data provided in the scenario for **Sylvia Wu** in the Reflective Practice display. Her reports of flulike symptoms provide the nurse with subjective data. Hearing her cough, noting any sputum produced, inspecting her throat for redness and irritation, and checking her temperature would provide the nurse with objective data that help to clarify and substantiate the patient’s reported symptoms.

Sources of Data

Patient

The patient is the primary and usually the best source of information. Unless specified otherwise, the data recorded in the nursing history are assumed to have been collected from the patient. Most patients are willing to share information when they know it is helpful for planning their care. (See the accompanying feature box, Through the Eyes of a Student.) Although subjective data collected from the patient are usually accurate, you should be alert for certain difficulties. For example, a patient who is acutely ill may not be able to communicate adequately if the pain is severe or if consciousness is altered. An emotionally upset patient may distort information; for example, patients who are fearful because they think their illness may threaten their work or life may deny certain symptoms or deliberately give misleading facts. If you become aware that a patient’s report of symptoms differs from physical findings or data obtained from other sources, note this and explore the cause of the discrepancy.

Data from patients with limited mental or communication capacity, such as young children and older adults with dementia, cannot be relied on as accurate. However, learn early to avoid the mistake of too quickly judging that a family member is a better source of information than the patient. Children and people with decreased mental capacity or impaired verbal ability should be encouraged to respond to interview questions as best as they can. Automatically turning to a family member, friend, or caregiver for information communicates powerfully that you either have no time for the patient to express their needs or mistakenly doubt the patient’s ability to communicate these needs.

Family and Significant Others

Family members, friends, and caregivers are especially helpful sources of data when the patient is a child or has limited capacity to share information with the nurse. Partners can supply information concerning their spouses. Friends often accompany a patient to a health facility and can supply useful information. Take care to determine that the patient does not object to you gathering data from family and friends, and also that family and friends want to participate. Also, everyone involved should clearly understand the confidentiality of this data. Whenever data are gathered from support people, indicate this in the nursing history.

Through the Eyes of a Student

During my chronic medical–surgical rotation, my clinical group was placed on an oncology floor. My first thought was “Oh no, not the cancer floor!” The word *fear* didn’t even begin to describe how I felt. These patients had enough problems without some “green” nursing student aggravating them all day. I kept thinking these people are extremely ill and won’t want to be bothered by my intruding questions.

Nonetheless, I knew I had to do it. Not only did I have to take care of this patient all day, but I also had to develop a database and care plan. I knew I would have to do a lot more than give him his morning care and leave him alone. I would have to carry on an extended conversation with this patient to get all the information I needed.

As if all of this wasn't enough to make me throw in the white flag, when my patient assignment was given, I discovered my patient was a man only 1 year older than me. A 28-year-old man with terminal cancer—this was too scary!

Clinical day came, as I knew it would, and I was shaking. I walked in that room and together the patient and I planned his care. I explained to him the things I needed to talk about with him and I couldn't believe it—he didn't tell me to go away! We talked at length about his disease process and how it had affected his plans and goals. He opened up to me about his spirituality, his relationships with friends and family, and other personal subjects. Periodically, he would cringe, and I could tell it was time for a break. He was hurting too badly to go on at that time.

At the end of that day, my viewpoint was totally different than it had been that morning. I walked away from that room and off that floor feeling like I had made a difference for this person. We had shared a lot and he seemed so appreciative for the time I took to talk with him. The information he shared helped me to develop a better care plan that was more responsive to his particular needs. The amazing part was that all I had to do was just be myself and allow him to do the same and our day flowed smoothly. The lesson I learned here was important for me: Cultivate competence, keep calm and hold on to compassion, and nursing offers many rewards!

—Nancy E. Driskill, Southeast Missouri State University
Cape Girardeau, Missouri

Patient Record

Records prepared by different members of the health care team provide information essential to comprehensive nursing care. You should review records early when gathering data—in some instances, before the first contact with the patient. This review helps to focus the nursing assessment and to confirm and amplify information obtained from other sources.

The patient's health record or chart, which lists such information as age, sex, occupation, religious preference, next of kin, and financial status, is one type of record. The health record includes information entered by various health care professionals such as physicians, social workers, dietitians, physiotherapists, and laboratory technicians.

FIGURE 15-5. Nurses can learn a great deal about a patient's health habits, patterns, and responses to illness by talking with other nurses, physicians, social workers, and other members of the health care team. This exchange of information is particularly important when patients transfer from one health care setting to another, or to home.

For **Susan Morgan**, the 34-year-old patient recently diagnosed with MS, the nurse would review her medical record for information related to her diagnosis and treatment plans, including specialized consultations and therapy, as well as her current home situation. This information would help the nurse determine the approach to performing the nursing history and physical examination, as well as planning her care.

If you want your care to be supportive of the patient while responding to changes in health status, you must be familiar with the many sections of the patient record in addition to the documentation of the nursing care plan and nursing notes. The following parts of the patient record are important sources of data.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

MEDICAL HISTORY, PHYSICAL EXAMINATION, AND PROGRESS NOTES

These parts of the record include the findings of physicians and nurse practitioners as they assess and treat the patient; they focus on identifying pathologic conditions and their causes and on determining the medical regimen for treatment.

CONSULTATIONS

The patient's health care providers may invite specialists to assess and treat the patient. The focus of these parts of the record is additional findings related to the patient's medical diagnosis and treatment.

REPORTS OF LABORATORY AND OTHER DIAGNOSTIC STUDIES

Reports of laboratory studies and other diagnostic tests, such as radiographs, include objective data that can either confirm or conflict with data collected during the nursing history or examination. Diagnostic studies help clinicians establish a diagnosis and monitor the patient's response to treatment. The results of these studies may also help nurses evaluate the success of nursing interventions.

REPORTS OF THERAPIES BY OTHER HEALTH CARE PROFESSIONALS

Other health care professionals who interact with the patient also record their findings and note what progress the patient is making in their specific areas—for example, nutrition, physical therapy, spiritual health, or speech therapy. These reports also help the nurse assess the patient's progress and help determine the patient's ability to return home and manage care independently. For example, a nurse would carefully check a speech therapist's evaluation of a patient's ability to swallow while working with a dietitian to develop and administer the care plan for nutrition via a feeding tube.

Records of previous admissions for health care and records from other health facilities, such as a social service facility or a home health care facility, are also valuable sources of data. They contain information about the patient's previous medical or surgical problems and response patterns, which may be important determinants of the current care plan. See Chapters 8, 11, and 20 for a description of the critical information that should be shared when patients are "handed off" or transitioned from one caregiver or team to another.

Assessment Technology

Nurses can also gain valuable data about patients from technologies such as cardiac and respiratory monitors. For example, a patient's bedside monitoring can provide round-the-clock information on blood pressure, heart rate, respirations, and cardiac activity.

Other Health Care Professionals

Nurses can learn a great deal about a patient's normal health habits and patterns and response to illness by talking with other nurses, physicians, social workers, and others on the health care team (Fig. 15-5 on page 418). Although such communication is always important, it is especially critical when patients are transferred from home to an institution or from one hospital or institution to another. The only way to ensure continuity of care is to make special efforts to share pertinent information.

Nursing and Other Health Care Literature

To obtain a comprehensive patient database, it may be necessary to consult the nursing and related literature on specific health problems. For example, a nurse who has not cared for a patient with Paget disease before should read about the clinical manifestations of the disease and its usual progression to know what to look for when assessing the patient. In addition to information about medical diagnoses, treatment, and prognosis, a literature review offers nurses important information about nursing diagnoses, developmental norms, and psychosocial and spiritual practices that is helpful when assessing and caring for patients.

For **Sylvia Wu**, the possible diagnosis of a virus that is potentially lethal is very frightening. To provide the most appropriate care, the nurse would need to know as much as possible about the disease. Then the nurse would be better able to act as an advocate for the patient.

Methods of Data Collection

The nursing history and physical assessment are primary components of data collection (see Chapter 27). These data may be documented on separate assessment tools or incorporated into a combined database assessment form, as shown in Figure 15-2 on page 408.

Observation is a key nursing skill when performing both the nursing history and the physical examination. **Observation** is the conscious and deliberate use of the five senses to gather data. Skilled nurses observe and interpret meaningful stimuli (data) in each nurse–patient interaction. You can develop such observation skills by training yourself to carefully observe the following each time you encounter a patient:

- What are the patient's current responses (physical and emotional) to their situation? Be alert to signs of distress—difficulty breathing, bleeding, pain, heightened anxiety—as well as anything out of the ordinary, such as sudden eruption of rash or a change in level of consciousness.
- What is the patient's current ability to manage their care (need for additional information or nursing assistance)?
- What factors are relevant in the immediate environment? Consider the safety of the environment as well as the functioning of equipment (e.g., intravenous therapy, oxygen, drains). Who are the people in the room and at home? What are the temperature and odor of the room?
- What other factors are relevant in the larger environment (hospital or community)?

Nursing History

Ideally, the nursing history captures and records the uniqueness of the patient so that care may be planned to meet the patient's individual needs. You should obtain the nursing history as soon as possible after a patient presents for care and then follow with the nursing physical assessment. You should clearly identify the patient's strengths and weaknesses; health risks, such as hereditary and environmental factors; and potential and existing health problems. While obtaining the nursing history, you focus on getting to know the person.

When obtaining the nursing history from **Sylvia Wu**, the nurse would ascertain when the patient had traveled in China, how long she had been there, how long she had been home, with whom she may have been in contact, and whether these people exhibited any signs and symptoms. This information is important for determining the patient's actual risk for developing a particular virus.

COMPONENTS OF A NURSING HISTORY

Components of a nursing history include:

- Profile: name, age, sex, race/ethnicity, marital status, religion, occupation, education
- Reason for seeking health care
- Health literacy and communication skills
- Usual health habits and patterns and related needs for nursing assistance
- Cultural considerations in relation to diet, decision making, and activities
- Current state of physical and mental health, functioning of body systems, degree of pain, and past medical and surgical history
- Current medications, allergies, and record of immunizations and exposure to communicable diseases
- Perception of health status and what health and illness mean to the patient, as well as usual responses or coping patterns
- Developmental history, family history, environmental history, and psychosocial history
- Patient's and family's expectations of nursing and of the health care team
- Patient's and family's educational needs and ability and willingness to learn
- Patient's and family's ability and willingness to participate in the care plan
- Whether an advance directive exists or if the patient wants help to prepare an advance directive
- Patient's personal resources (strengths) and deficits
- Patient's potential for injury

PATIENT INTERVIEW

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

You obtain the nursing history by interviewing the patient. An **interview** is a planned communication. You need strong interviewing skills to establish a successful working partnership with the patient, to communicate care and concern for the patient, and to obtain the necessary patient data. Many students find it helpful to role-play the nurse–patient interview before attempting this in a clinical setting. It is also helpful to watch how experienced nurses interview patients, create partnerships, and earn their trust. Figure 15-6 depicts a seating arrangement and distance from the patient appropriate for the interview. See the accompanying Guidelines for Nursing Care 15-1: Promoting a Caring Interview (on page 420) for tips on conducting an effective interview. The interview occurs in four phases: the preparatory phase, introduction, working phase, and termination. More detailed information on interviewing techniques is provided in Chapter 8.

FIGURE 15-6. In the interview, both the seating arrangement and the distance from the patient are important in establishing a relaxed and comfortable environment for data collection. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

Physical Assessment

Physical assessment is the examination of the patient for objective data that may better define the patient's condition and help the nurse plan care. The physical assessment normally follows the nursing history and interview and may verify data gathered during the history or yield new data. Health care providers traditionally have performed the intake physical assessment, which commonly is the mechanism of entry into the health care delivery system as well as the basis for medical treatment. Some nurses in advanced practice roles perform comprehensive intake physical assessments similar to those of their physician colleagues, which identify health and illness states, and then recommend or prescribe appropriate care. In any case, all nurses conduct selected aspects of physical assessment for nursing purposes.

Unlike the physical assessment performed by the clinician to identify pathologic conditions and their causes, the nursing physical assessment focuses primarily on the patient's functional abilities. If a neurologic deficit is present, the nurse identifies how it affects the patient's reasoning and sensorimotor abilities. For example, a patient who has had a cerebrovascular accident (brain attack or stroke) is examined to determine ability to comprehend and communicate information and perform the tasks of everyday life.

The physical assessment for **Susan Morgan**, the young woman newly diagnosed with MS described at the beginning of the chapter, would include investigation of the patient's muscle strength and endurance level and the effects of MS on the patient's ability to perform daily activities. In the physical examination the nurse would be alert for indications of fatigue or inability to complete specific activities. This information would help the nurse respond appropriately to the patient's concerns about her marriage.

The purposes of the nursing physical assessment include the appraisal of health status, the identification of health problems, and the establishment of a database for nursing interventions (Fig. 15-7).

Nurses practicing in different settings may use different physical assessment techniques for different purposes. Nurses in the medical intensive care unit use sophisticated, high-technology assessment techniques, whereas nurses in a rehabilitation center use a wide range of physical assessment skills that focus on identifying functional and nonfunctional response patterns to disabilities.

The nursing physical assessment involves the examination of all body systems in a systematic manner, commonly using a head-to-toe format; this is called the **review of systems (ROS)**. Four methods are used to collect data during the physical assessment:

- *Inspection*: the process of performing deliberate, purposeful observations in a systematic manner
- *Palpation*: use of the sense of touch to assess skin temperature, turgor, texture, and moisture as well as vibrations within the body
- *Percussion*: the act of striking one object against another to produce sound
- *Auscultation*: the act of listening with a stethoscope to sounds produced within the body

FIGURE 15-7. The nurse conducts a physical examination. No matter what the setting or the age of the patient, the physical examination should include appraisal of health status, identification of health problems, and establishment of a database for nursing intervention. (*Source:* Used with permission from Shutterstock. *Photo by Antoniodiaz*.)

Guidelines for Nursing Care 15-1

PROMOTING A CARING INTERVIEW

These guidelines can help you to establish trust, create a positive attitude, and reduce anxiety—both yours and the patient's!

How to Establish Rapport

Before you go into the interview

- Get organized: Be sure that you have everything you need to have with you.
- Prepare for the interview by reading current and past records and reports.
- Don't rely on memory: Have a printed or electronic assessment tool to guide the questions you will ask.
- Plan enough time: The admission interview usually takes 30 to 60 minutes.
- Ensure privacy: Make sure that you have a quiet, private setting, free from interruptions or distractions.
- Get focused: Clear your mind of other concerns. Say to yourself, "Getting to know this person is the most important thing I have to do right now."
- Visualize yourself as being confident, warm, and helpful: This helps you to be confident, warm, and helpful—your genuine interest comes through.
- Approach the patient with an open mind and be aware of any stereotypes or prejudices that might affect this encounter.

When you begin the interview

- Begin by sitting at eye level with the patient (Fig. 15-6 on page 419). Chairs placed at right angles to each other and about 3 to 4 ft (0.9 to 1.2 m) apart facilitate an easy exchange of information. If the patient is in bed, placing the chair at a 45-degree angle to the bed is helpful.
- Introduce yourself and give your name and position. This sends the message that you accept responsibility and are willing to be accountable for your actions. This is especially important if you are a student.
- Verify the person's name and ask what they would like to be called. This communicates your respect for the patient and that you recognize the patient as an individual with likes and dislikes.
- In unusual situations in which a contractual agreement that clearly identifies the responsibilities of both patient and nurse is indicated (e.g., a gerontologic nurse entrepreneur), terms are discussed at this time.

During the interview

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Give the person—not your notes or computer—your full attention. This will take practice.
- Avoid rushing. Become comfortable with the patient's silence.

How to Listen

- Listen actively—listen for feelings as well as words.
- Let the person know in a diplomatic manner when you see body language that sends a message that conflicts with what is being said, for example, "You say that you aren't having pain, but you look uncomfortable to me."
- Use short, supplemental phrases that let the person know you understand and encourage the person to continue, for example, "I see," "Mmhm," and "Then what?"
- Be patient if the person has a memory block.
- Avoid the impulse to interrupt.
- Allow for pauses in conversation. Silence gives both you and the person time to gather thoughts, and allows you to reflect on the accuracy of the information the patient has provided.

How to Ask Questions

- Ask questions about the person's main problems first, for example, "What are the main reasons you are here today?" and "What do you hope happens today (or during your visit/time here)?"
- Focus your questions to gain specific information about signs and symptoms, for example, "Show me where the problem is" and "Can you describe how this feels more specifically?"
- Don't use leading questions, for example, "You don't smoke, do you?"
- Do use exploratory statements, for example, "Tell me more about your sleeping patterns."
- Use communication techniques that enhance your ability to think critically and get the facts:
  1. Use phrases that help you see the other person's perspective, for example, "What are the problems as you see them?"
  2. Restate the person's own words, for example, "Let me repeat what you said to make sure I understand."
  3. Ask open-ended questions, for example, "How are you feeling?" rather than "Are you feeling well?"
  4. Avoid close-ended questions—those requiring a one-word answer—unless the person is too ill to elaborate or you are trying to clarify a response by getting a yes or no.

What to Observe

- Carefully assess areas connected to verbal complaints.
- Use your senses.
- Note general appearance.
- Observe body language. Does the person appear comfortable? Nervous? Withdrawn? Apprehensive? What behaviors do you see?
- Notice interaction patterns. Be aware of the person's responses to your interviewing style (e.g., sometimes cultural and personal differences create communication barriers).

How to Terminate the Interview

- Give a warning, for example, "We have 5 minutes to finish up … let's be sure we have covered the most important things you want us to know."
- Ask people to summarize their most important concerns and then summarize the most important concerns as you see them.
- Ask, "What else?," for example, "Is there anything else you want us to know to better plan your care?"
- Offer yourself as a resource, for example, "Let me know if anything changes or you have any questions."
- Explain care routines and provide information about who is accountable for nursing care decisions. Patients are often confused about who is responsible for what.
- Explain where the data being recorded are stored, how they will be used, and who has access to them.
- End on a positive note and encourage the person to become an active participant, for example, "We have a good start here. We want you to be actively involved in making decisions about your care."

Source: Adapted from Alfaro-LeFevre, R. (2014). *Applying nursing process. The foundation for clinical reasoning* (8th ed., pp. 62–65). Wolters Kluwer Health/Lippincott Williams & Wilkins.

Table 15-3 Patient Variables That Can Negatively Influence an Interview and Suggested Nursing Responses

PATIENT VARIABLES	EFFECT ON INTERVIEW	NURSING RESPONSE
High anxiety	Patient may speak rapidly or	Normalize anxiety: "Many people

	incoherently and may jump from one topic to another; patient may deny or misrepresent what they are experiencing.	find it difficult to talk about their health and become anxious"; approach patient gently, speak slowly and softly; underscore importance of the patient sharing what they are experiencing so that nurses can help.
Pain	Patient offers clipped responses and "yes" or "no" answers whenever possible; overriding concern is pain relief.	Do everything possible to make patient comfortable before the interview, try nonpharmacologic remedies and if necessary obtain an order for and administer pain medication; if pain persists, obtain only vital data and defer remainder of interview until patient is more comfortable.
Language difficulty (patient not fluent in nurse's language because patient speaks a different language, has a limited education, or fears saying the "wrong thing")	Vital patient data will not be communicated; patient may mistakenly be labeled "indifferent" or "noncommunicative."	Speak clearly (do not raise voice) using simple language; whenever possible, obtain the assistance of an interpreter and follow facility guidelines.
Previous negative experience with nurses or health care delivery system	Patient is aloof, unwilling to participate in interview; general attitude: "Why should I waste my time telling you anything … it won't do me any good."	"I know other people who have had a tough time with nurses or the system … life isn't perfect … but how about giving us a chance this time to show you what nurses can do?" Communicate respect for the patient and competence.
Unrealistic expectations of health care professionals	Patient expects nurses and other health care professionals magically to know everything about the patient and to "take care" of the patient; "surrenders" self to the system—"you know best" attitude.	Communicate clearly that no one knows or understands the patient like the patient does, and invite the patient to become involved in their care; "No two people are alike, and unless you tell me a little more about yourself and how you are feeling, there is no way we'll be able to plan good care."

Nurses may also use physical assessment skills to evaluate selected body systems. These techniques and the basic skills for physical assessment are described in Chapter 27.

Problems Related to Data Collection

Common problems that occur in data collection include inappropriate organization of the database, omission of pertinent data, inclusion of irrelevant or duplicate data, erroneous or misinterpreted data, failure to establish rapport and partnership with the patient, recording an interpretation of data rather than observed behavior, and failure to update the database. Tables 15-3 and 15-4 describe possible causes and remedies for such problems.

IDENTIFYING CUES AND MAKING INFERENCES

Nurses now use the language of cues and inferences to describe the early analysis of data. The subjective and objective data you identify ("the patient does not respond when I speak to him on his left side") is a **cue** that something may be wrong. The judgment you reach about the cue (the patient's hearing may be impaired on his left side) is an **inference**. See Figure 15-8 to see a nurse responding to nonverbal cues.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 15-8. A nurse responds to a patient's nonverbal cues during a home visit. (*Source:* Used with permission from Shutterstock. *Photo by fizkes*.)

Table 15-4 Common Problems of Data Collection, Possible Causes, and Suggested Remedies

PROBLEM	POSSIBLE CAUSES	SUGGESTED REMEDIES
Database inappropriately organized	Failure to plan for the assessment by identifying needed data; use of inappropriate tools for data collection	Review the guidelines for specifying pertinent data. Consider modifying tool for data collection or select an alternative tool.
Pertinent data omitted	Not following up on cues during data collection; inappropriate guidelines	Identify potentially relevant factors in advance of collection. Practice interview strategies.
Irrelevant or duplicate data collected	Failure to identify specific purpose of data collection; failure to review available patient records; use of inappropriate tools for data collection	Determine specific purpose of data collection for each patient. Consider existing data before initiating collection. Consider modifying data collection tool or selecting alternative.
Erroneous or misinterpreted data collection	Failure to observe carefully or validate during data collection; interviewer prejudices or stereotypes	Sharpen observation skills by independently observing the same situation with a peer and comparing notes afterward. Role-play several validation techniques.
Failure to establish rapport	Failure to establish sufficient rapport or use appropriate communication techniques with patient; failure to know what information is wanted	Review and practice communication techniques discussed in Chapter 8. Role-play several explanations of purpose of data collection. Identify general data desired before collection.
Interpretation of data is recorded rather than the observed behavior	Nurse jumps to hasty conclusion about patient's behavior and deprives others of exploring with patient possible causes of the behavior; deficient validation	Review the distinction between data and interpretation of data. Practice documenting observed patient behavior concisely.
Failure to update the database	Erroneous belief that assessment is concluded after the initial database is recorded; low priority attached to ongoing data	Recollect that it is impossible to give quality, individualized care without knowledge of changes in the patient's status. Ongoing

	collection	data collection is critical to the deletion or modification of old problems and the identification of new problems.

Until you check the patient's hearing, you cannot be sure that your inference is correct. Inferences may be validated in multiple ways:

- Physical examination, using the proper equipment and procedure (you may need to have an expert confirm your findings)
- Clarifying statements ("You said this is not a problem, but I sense you may still be worried.")
- Sharing your inferences with other respected members of the team and seeking consensus
- Checking your findings with research reports, textbooks, or journals
- Comparing cues to your knowledge base of normal function
- Checking consistency of cues

Figure 15-9 illustrates the process for validating inferences.

The nurse may validate data during collection or at the end of the data-gathering process. When it is clear that the data are correct, the nurse is ready to analyze the data and formulate nursing diagnoses/health problems—the next phase of the nursing process. Figure 15-10 (on page 424) illustrates the role clinical reasoning and judgment plays in moving from assessment to diagnosis/problem identification.

VALIDATING DATA

Validation is the act of confirming or verifying. The purpose of validating is to keep data as free from error, bias, and misinterpretation as possible. Validation is an important part of assessment because invalid information can lead to inappropriate nursing care. Because it is neither possible nor necessary to validate all data, nurses need to decide which items need verification. For example, data need to be verified when there are discrepancies: a patient tells you he is fine and has no concerns, but you note that he demonstrates tense body musculature and seems curt in his responses. When there is a discrepancy between what the person is saying and what you are observing, validation is necessary to determine accuracy. Validation in this instance may take the form of your saying, "You tell me you feel fine, but right now your body and behaviors are telling me something else. Tell me more about this."

Data also need verification when they lack objectivity. For example, you suspect that the patient hears in one ear but does not seem to hear well in the other. You should validate the data before proceeding and should determine whether the patient does indeed have a hearing problem. Suspicions are not objective. In this instance, you need to test the patient's hearing in both ears. Speaking toward the suspected better ear, you explain, "It seems to me that you hear better out of one ear than the other. I would like to test this. I'll bring a watch slowly toward your right ear first and then toward your left. Please look straight ahead and tell me when you first hear the watch ticking." You can then record how far the watch was from each ear when the patient first heard it ticking.

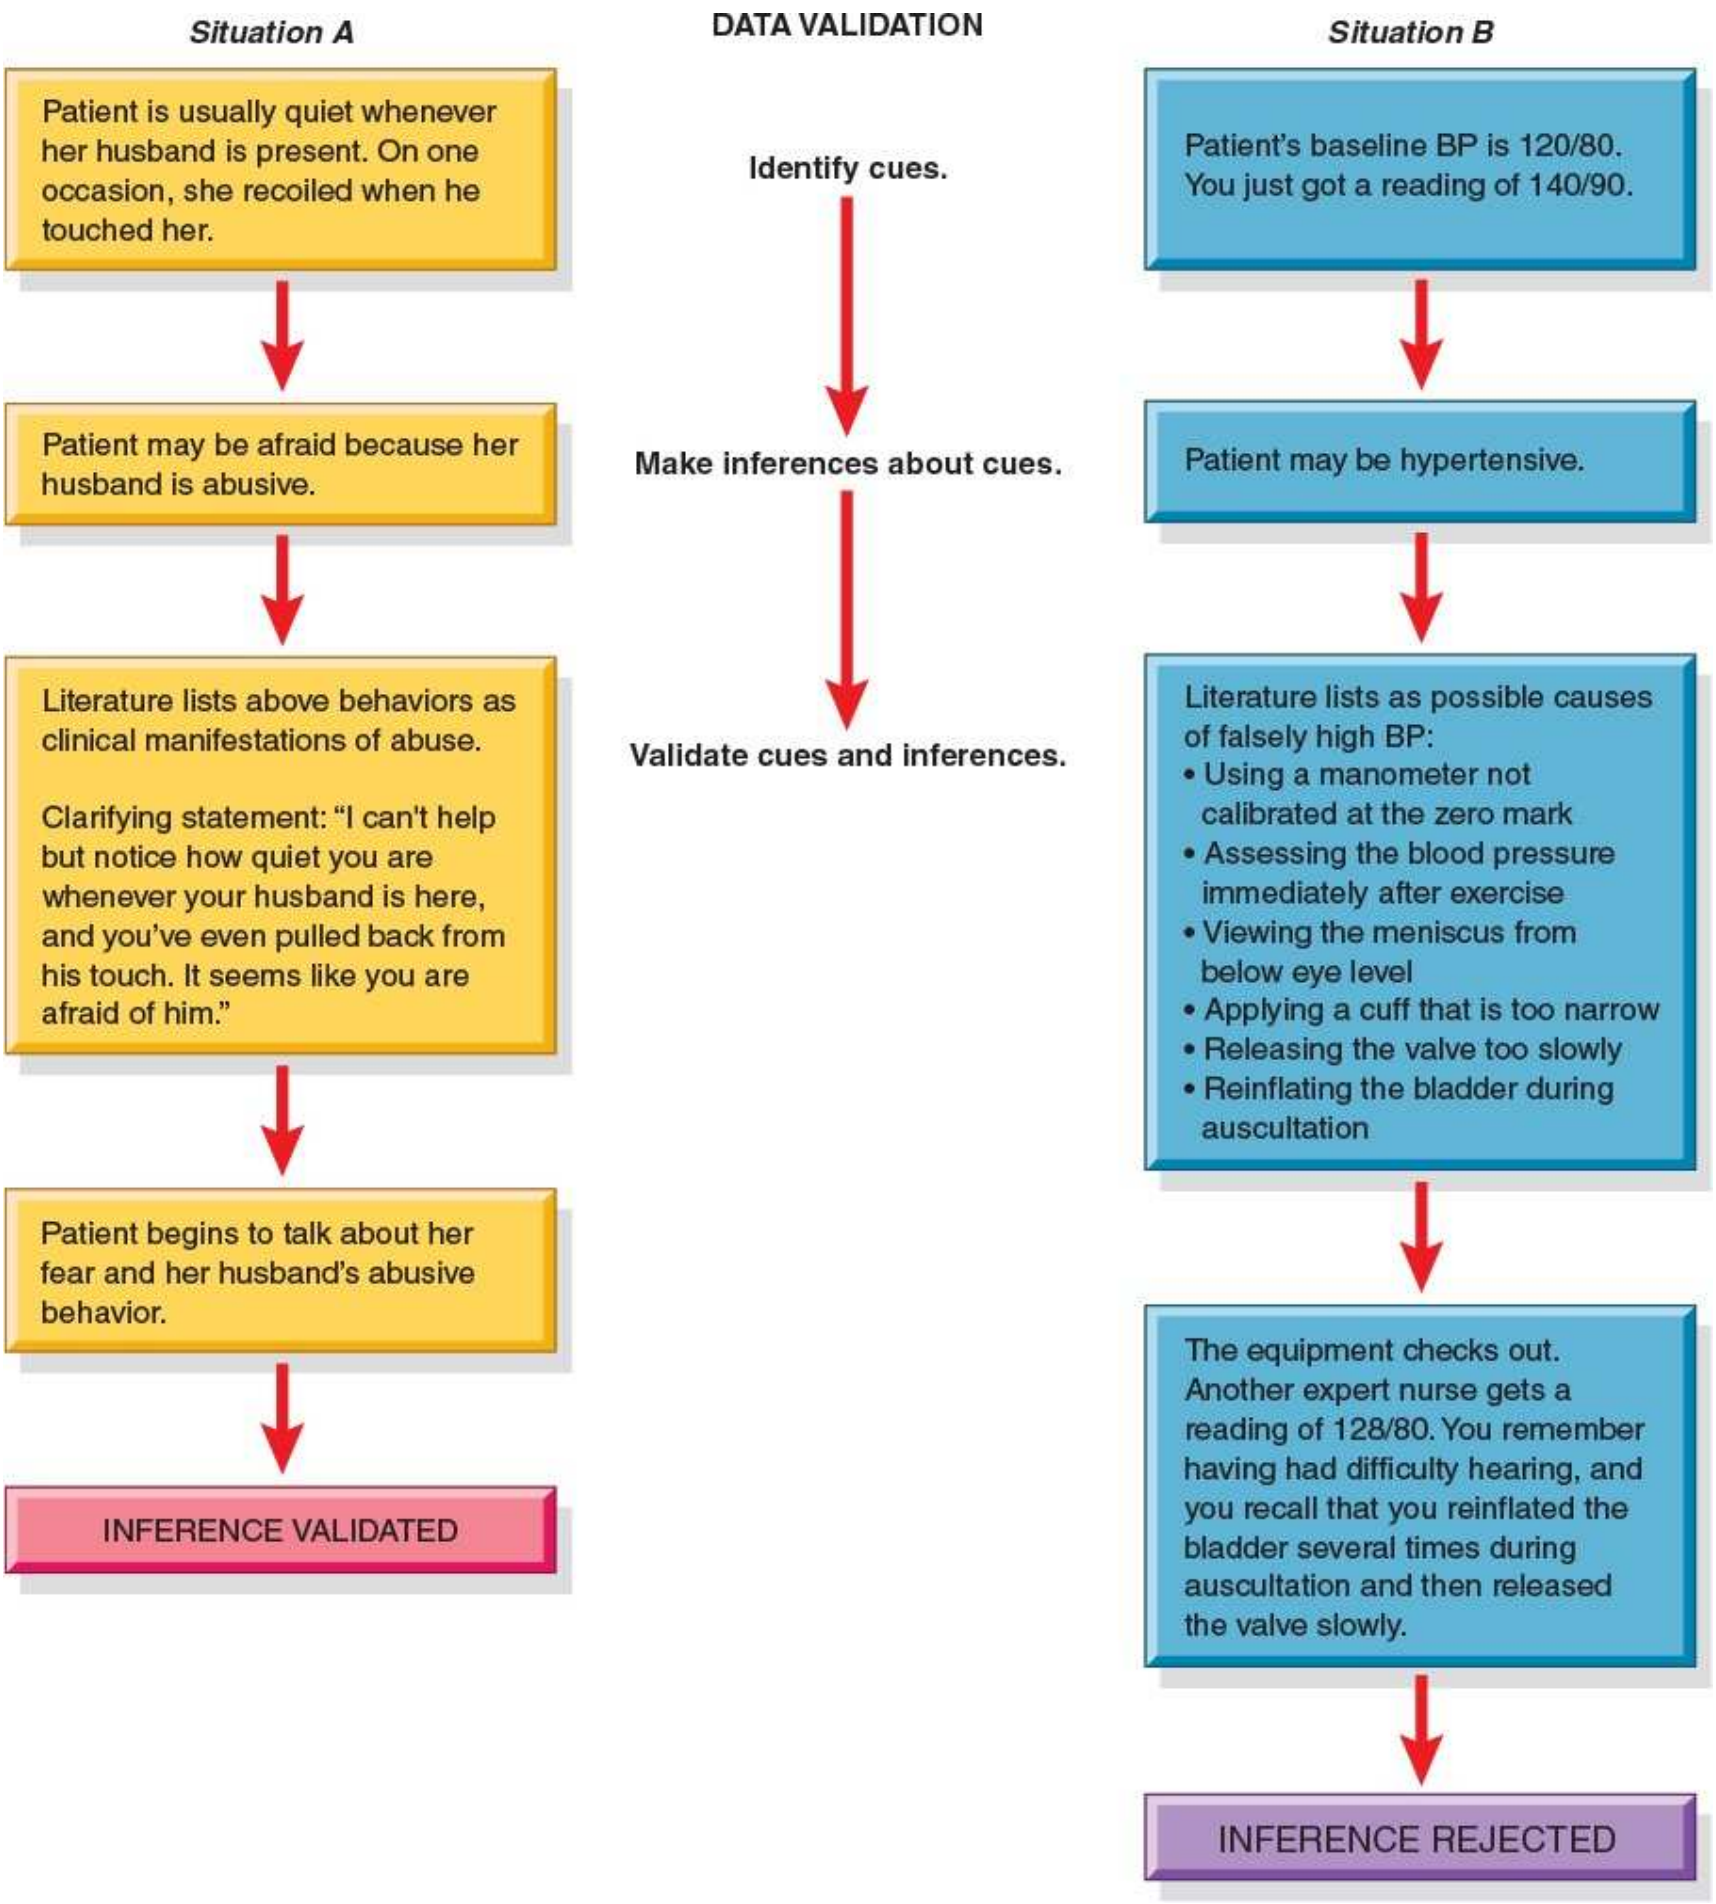

FIGURE 15-9. The process used to validate cues and inferences.

Concept Mastery Alert

Whenever there is any data discrepancy or conflict, the nurse must investigate further, gathering focused information to support, confirm, or negate the suspicions.

CLUSTERING RELATED DATA AND IDENTIFYING PATTERNS

As described earlier, as you prepare to collect your data you also decide how to organize or cluster the data. Table 15-1 on page 415 illustrates three holistic models (Maslow's human needs, Gordon's functional health patterns, and human response patterns) along with the body system medical model. Once you have organized your data according to the purpose of your assessment, you begin to look for and test your initial impressions about patterns of human functioning. Alfaro-LeFevre (2014) recommends testing your first impressions to decide what's relevant, making tentative decisions about what the data suggest, and focusing your assessment to gain more in-depth information to better understand the patient's situation. She stresses the importance of trying to learn why the pattern came to be, emphasizing that there is usually more than one contributing factor because health problems are complex.

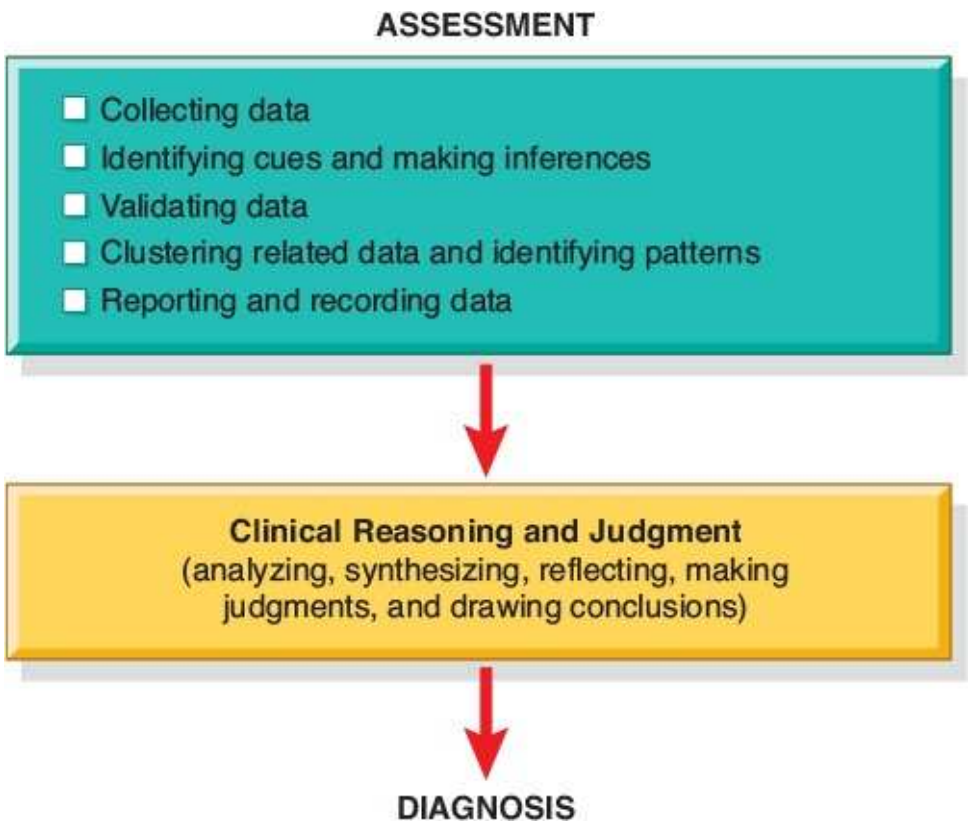

FIGURE 15-10. How the phases of assessment set the stage for diagnosis/problem identification. (*Source:* Reprinted with permission from Alfaro-LeFevre, R. [2014]. *Applying nursing process. The foundation for clinical reasoning* [8th ed., p. 49]. Wolters Kluwer Health/Lippincott Williams & Wilkins.)

REPORTING AND RECORDING DATA

The patient data the nurse collects, both initially and as patient contact continues, are of no benefit to the patient and the health care team unless they are appropriately communicated. See the Legal Alert box. Appropriate communication involves correct timing and proper documentation.

Legal Alert

Nurses are responsible for alerting the appropriate health care professional whenever assessment data differ significantly from the patient's baseline, indicating a potentially serious problem. Interventions for which the nurse may be legally responsible include increasing the frequency of assessments and initiating necessary changes in the treatment regimen.

Timing

Data should be reported verbally immediately whenever assessment findings reveal a critical change in the patient's health status that necessitates the involvement of other nurses or health care professionals. A nurse who observes an elevated temperature of 103.2°F (39.5°C) in a patient scheduled for surgery that morning must report this to the charge nurse and to the surgeon, who might then cancel surgery. Failure to communicate this finding could result in the patient's receiving preoperative sedation, being taken to the operating room, and even having the surgery performed under less than optimal conditions. Similarly, a nurse who hears a patient making suicidal remarks must communicate this information to the health care team so that all are alerted to the danger and so that suicide precautions may be taken immediately.

A nurse who is unsure of the significance of a particular finding should consult with another nurse. In some situations, years of experience are needed to distinguish significant from insignificant findings. Neither ignorance nor the fear of appearing less than competent justifies failure to report critical data.

The nurse would need to report **Sylvia Wu's** symptoms along with the underlying history of travel to China immediately to the appropriate health care personnel. Doing so ensures that the necessary precautions are

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

taken to reduce the risk of infection transmission of a potentially highly communicable virus.

Documentation

The patient's initial database is entered into the computer or recorded in ink, using the designated facility protocol or forms, the same day the patient is admitted to the facility. If, for any reason, important data cannot be obtained during the initial assessment, this should be documented so that they are obtained as soon as possible. Objective and subjective patient data should be summarized and written so that the data communicate a unique sense of the patient and are comprehensive, concise, and easily retrievable. The data should be written legibly, using good grammar and only standard medical abbreviations. To facilitate quick data retrieval, data should be presented under clearly marked headings.

Whenever possible, subjective data should be recorded using the patient's own words within quotation marks: "I feel tired from the moment I first get up in the morning. It seems I have no energy at all." Patient reports may also be paraphrased: Patient reports feeling dyspneic, has difficulty catching breath when walking one flight of stairs.

Avoid the tendency to record data using nonspecific terms with different meanings or interpretations—words such as *adequate, good, average, normal, poor, small, large.* One nurse's idea of what "average" fluid intake is may be very different from that of another nurse. Always be specific. Chapter 20 offers general documentation guidelines.

Privacy, Confidentiality, and Professionalism

One of your primary ethical responsibilities is safeguarding the privacy of your patients. When gathering patient data, you will learn much about patients that they wish to keep private, and patients have every right to expect that you will maintain their privacy. If family members are with a patient you plan to assess you need to ask them to step outside or get the patient's consent for them to be present. Please review the privacy information in Chapter 7 and be sure you are familiar with your institution's policies on privacy and on the requirements of the Health Insurance Portability and Accountability Act (HIPAA). Recently, the ANA (www.nursingworld.org) and the National Council of State Boards of Nursing (https://www.ncsbn.org) united to provide guidelines on social media for nurses. Check their websites for organization guidelines upholding professional boundaries in a social networking environment. You will also find a statement on social media usage and maintaining privacy, confidentiality, and professionalism on the National Student Nurses' Association website, www.nsna.org.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the goal of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop expertise in assessing patients' health status and well-being, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following during the assessing phase of the nursing process:

- Did your preparation for the assessing experience bring you to the interview and physical examination feeling confident in your ability to gather reliable, accurate, and complete data while inspiring the patient's confidence and trust?
- How confident are you that the data you reported and recorded accurately communicates the health problems, issues, risks, and strengths of the patient? How successfully have you communicated who this patient/family are to your interdisciplinary colleagues?
- If you were unsure of any of your findings, perhaps had difficulty feeling a pulse, did you ask readily for help?
- Were you aware of any stereotypes or prejudices that might have negatively influenced the clinical encounter? If yes, how did you address these?
- Was patient/family participation in the process at an optimal level? How might you have better engaged the patient and family? As you concluded your assessment, did the patient know your name, know what to expect of you and of nursing, sense that you are competent, respectful, and caring, and know what is expected in terms of developing the care plan and participating in its execution?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of assessing their health problems and identifying and tapping their strengths? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Working with another student, interview patients in both their home and institutional settings, and record your findings separately. Make a list of the objective and subjective data you gather about each patient interviewed and the inferences you make from these cues. Compare your data lists and inferences. Describe to each other how you plan to validate your inferences. Explore possible reasons for the differences you discover.

. Allow another student to perform a comprehensive nursing assessment (interview and physical assessment) on you. Reflect on what you experienced. Offer the student feedback about which of their behaviors were helpful, comforting, or distressing. Change roles and talk about what you learned from this experience.
. Collect several different forms for recording the initial comprehensive nursing assessment (hospital, long-term care facility, home care, school of nursing forms). Identify differences and explain them. Experiment with using the different forms, and make a list of features that help you get all the data you need in the easiest way possible. Review Table 15-3 on page 421. What other patient variables might negatively influence an interview? Nursing variables? How should you address these?
. You are helping another student with a dressing change when he pulls out his cell phone and takes a picture of the stage IV pressure injury exposing bone and muscle on the patient's sacrum and says, "This is really gross." How do you respond and why?

PRACTICING FOR NCLEX

. A nursing student tells the clinical instructor that their patient is fine and has "no complaints." Which question by the faculty coaches the student to provide evidence that supports their assessments?

a. "Could you tell me how you validated this?"
b. "Do you think your patient feels free to share their concerns?"
c. "That's good to hear. Tell me about the care you provided."
d. "Please reassess the patient; they were admitted with a serious problem."

. A nursery nurse notifies the nurse practitioner (NP) that a newborn has signs of jaundice. The NP performs a brief skin assessment, then orders a blood test for bilirubin levels. Which type of assessment has the NP performed?

a. Comprehensive
b. Initial
c. Time-lapsed
d. Quick priority

. The nurse is admitting a pregnant patient to the hospital for treatment of pregnancy-induced hypertension. The patient asks the nurse, "Why are you doing a history and physical exam when the doctor just did one?" What statements will the nurse use to explain the primary purpose of the nursing assessment? Select all that apply.

a. "The nursing assessment will allow us to plan and deliver individualized, holistic nursing care that draws on your strengths."
b. "It's hospital policy. I know we ask a lot of questions, but I will try to make this quick."
c. "As a nursing student, I need to develop assessment skills about your health status and need for nursing care."
d. "This validates that your responses with the medical exam are consistent and that all our data are accurate."
e. "I will check your health status and see what kind of nursing care you may need."
f. "This is to determine the necessity for referring your nursing care needs to a health care provider."

. During shift report, a nurse says that a patient has no integumentary changes or skin care needs. During assessment, the nurse observes reddened areas over bony prominences. What action will the nurse take?

a. Correct the initial assessment form
b. Redo the initial assessment and document current findings
c. Conduct and document an emergency assessment
d. Perform and document a focused assessment of skin integrity

. A nursing student is performing a nursing history for the first time. The student asks the primary nurse how anyone learns all the questions needed to get complete baseline data. What would be the nurse's best reply?

a. "There's a lot to learn at first, but once it becomes part of you, you just ask the same questions over and over in each situation until you can do it in your sleep!"
b. "You make the basic questions a part of you and apply critical thinking to modify them, to help you plan quality care."
c. "It is really hard to learn how to do this well, as each history is different. I often feel like I'm starting fresh with each new patient."
d. "Don't worry about learning all of the questions to ask. Every facility has its own assessment form you must use."

. The nurse collects subjective and objective data during a patient assessment. When documenting, which data points will the nurse include as subjective data? Select all that apply.

a. Feeling nauseated
b. Edematous ankles
c. Feeling anxious about test results

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

d. Report of left arm tingling
e. Pain rated 7 on a scale of 1 to 10
f. Oral temperature of 101°F

. When a nurse enters the patient's room to begin a nursing history, the nurse notes the patient's spouse is present. After greeting them, what action will the nurse take?
a. Thank the spouse for being present
b. Ask the spouse if they want to remain
c. Ask the spouse to leave
d. Ask the patient if they would like the spouse to stay

. A nurse is performing an initial comprehensive assessment of a patient admitted to a long-term care facility. The nurse begins the assessment by asking the patient, "How would you describe your health status and well-being?" and, "What do you do to keep yourself healthy?" These questions reflect what model for organizing data?
a. Maslow's hierarchy of needs
b. Gordon's functional health patterns
c. Human response patterns
d. Body system model

. The nurse notes a temperature of 102°F in a patient scheduled for surgery in 30 minutes. As the patient has been afebrile and asymptomatic until now, what action will the nurse take next?
a. Inform the charge nurse
b. Notify the surgeon
c. Reassess the temperature
d. Document the finding in the electronic health record

. During a change-of-shift report, a nurse receives information that a patient admitted with hypertensive emergency has prescriptions for antihypertensive medications given at 8 AM and due at 8 PM. During the 8:00 PM assessment, the patient's blood pressure is 90/60, and they report slight dizziness upon standing. After returning the patient to bed, what action will the nurse take?
Exhibit: Electronic health record, vital signs
8:00 AM 182/100
12:00 PM 168/98
4:00 PM 160/88
a. Record the BP in the electronic health record
b. Notify the health care provider
c. Administer the 8:00 PM medications
d. Place the patient flat in bed

. During an assessment, the nurse on a neurologic unit finds the patient confused to time and place but able to state their name. How will the nurse best record this in the electronic health record?
a. Is more confused than yesterday
b. States the year is 1975 and they are at a wedding
c. Disoriented to person, time, and place
d. Patient's speech is garbled

. A nursing student is assigned to the emergency department (ED) to shadow the triage nurse. What activity will the student expect to perform?
a. Acute and emergency interventions
b. Daily care and assistance with ADLs
c. Assessment and prioritization of care
d. Care planning for return to home

. The nurse is assigned to care for a group of patients. Which patient will the nurse assess first?
a. Postoperative patient reporting pain 4/10
b. Individual with pneumonia whose WBCs are now 7,000
c. Adolescent with a burn to the face who is going home tomorrow
d. Patient's pulse oximetry reading 89%, as reported by AP

. The nurse assessing a patient plans to use the OLD CARTS mnemonic to organize their questions. What questions will the nurse include in the assessment? Select all that apply.
a. "Can you tell me when the problem began"?

b. "Where were you sitting when this started?"
c. "Have your symptoms stopped and/or started again?"
d. "Would you describe your pain as sharp, dull or burning?"
e. "What do you believe has caused this problem?"

. A nurse in the emergency department is assessing a young adult who has cognitive disability and is reporting severe abdominal pain. The patient is accompanied by the director of the group home where they live. When collecting data from this patient, which action reflects best practice?

a. Ask the assessment questions of the director.
b. Wait for the young adult's parents to arrive before performing the assessment.
c. Ask the young adult questions and validate with the adult present.
d. Perform the physical assessment, then the intake interview when the family arrives.

. A nursing student on the surgical unit is assigned to perform a review of systems using the head-to-toe format on a patient admitted for a fractured femur. Using this format, what system will the student assess first?

a. Genitourinary
b. Neurologic
c. Respiratory
d. Musculoskeletal

ANSWERS WITH RATIONALES

. **a.** The instructor is reminding the student that all data must be validated. Questioning the use of the word "fine" allows the nurse to determine if this is a social and reflexive response, and there may be another need the nurse can meet. Concluding that the patient does not trust the student is premature and is based on an invalidated inference. Saying "That's good to hear" and asking the student to describe the care provided is incorrect because it accepts the invalidated inference. Telling the student to reassess the patient because they were admitted with a serious problem is incorrect because it is possible that the condition is resolving.

. **d.** A quick priority assessment (QPA) is a short, focused assessment to obtain the most important information first. A comprehensive initial assessment is performed shortly after admission. The time-lapsed assessment is used to compare a patient's current status to baseline data obtained earlier.

. **a, e, f.** Medical assessments target data pointing to pathologic conditions, whereas nursing assessments focus on the patient's responses to actual and potential health problems. The initial comprehensive nursing assessment results in baseline data that enable the nurse to make a judgment about a patient's health status, the ability to manage their own health care and the need for nursing. It also helps nurses plan and deliver individualized, holistic nursing care that draws on the patient's strengths and promotes optimum functioning, independence, and well-being, and enables the nurse to refer the finding(s) to the health care provider or collaborate with other health care professionals where indicated. Citing hospital policy or student learning is a secondary reason, and although it may be true that a nurse may need to develop assessment skills, it is not the main reason for a nursing history and assessment. The assessment augments the medical examination but is not performed to check its accuracy.

. **d.** Perform a focused skin assessment for the new problem, documenting the current date. The initial assessment was entered in the permanent health record, correct at the time, and cannot legally be rewritten. An emergency assessment is performed for a life-threatening problem.

. **b.** Once a nurse learns what constitutes the minimum data set, it can be adapted to each patient situation. It is not true that each assessment is the same even when using the same minimum data set, nor is it true that each assessment is uniquely different. Nurses committed to thoughtful, person-centered practice individualize their questions to each patient and situation. When using a standard facility assessment tool the nurse must still use critical thinking to individualize questions or follow up on patient information.

. **a, c, d, e.** Subjective data are information perceived only by the affected person. Examples of subjective data are feeling nauseated, anxious, tingling, and experiencing pain. Objective data are observable and measurable data that can be seen, heard, felt, or measured by someone other than the person experiencing them. Examples of objective data are fever or 101°F or edema.

. **d.** The patient has the right to privacy and to determine who will be present during the nursing history and exam. The nurse does not presume the patient's preference, as the decision belongs to the patient, not their spouse.

. **b.** Gordon's functional health patterns begin with the patient's perception of health and well-being and progress to data about nutritional–metabolic patterns, elimination patterns, activity, sleep/rest, self-perception, role relationship, sexuality, coping, and values/beliefs. Maslow's model is based on the human needs hierarchy. Human responses include exchanging, communicating, relating, valuing, choosing, moving, perceiving, knowing, and feeling. The body system model is based on the functioning of the major body systems.

. **c.** The nurse validates assessment findings that deviate from normal patterns or are unsupported by other data. Should

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the initial measurement be in error, it would have been premature to notify the charge nurse or the surgeon. The nurse must be sure that all data are accurate prior to documenting and reporting. If there is a question about accuracy, the data should be validated before documenting.

. **b.** When assessment findings reveal a critical change in the patient's health status, the nurse reports the data (verbally) immediately. The nurse verifies the BP and notifies the health care provider, who may prescribe withholding blood pressure medications, assessment of orthostatic vital signs, among other actions. There is no indication the patient needs to lie flat at this time.

. **b.** While the patient is confused, it is most important to clearly describe the behavior for comparison to past and future behavior. Citing the actual year and events (orientation to time and place) provides context; "patient confused" is open to misinterpretation. Garbled speech refers to speech that is unclear; the patient may have difficulty with pronunciation or speak slowly, which is not necessarily reflective of confusion.

. **c.** The triage nurse screens patients to determine the extent and severity of their problems. They use highly specialized nursing knowledge and clinical reasoning and make clinical judgments to prioritize who must be seen immediately and who can wait. Patients in the ED are stabilized and transferred to the appropriate level of care; therefore, daily care, assistance with ADLs, planning for return home, and providing interventions are not part of the triage nurse's role. Should the patient need emergency interventions, the triage nurse moves the patient to the appropriate area in the ED.

. **d.** The nurse uses Maslow's hierarchy of needs to prioritize assessing the patient with hypoxemia, manifested by a pulse oximetry reading of 89%. The postoperative patient is reporting moderate pain; the patient with pneumonia has normal WBCs; the adolescent patient with a burn to the face is stable for discharge. These patients can be seen as soon as possible.

. **a, c, d.** The OLD CARTS mnemonic refers to **O**nset: "When did your symptom(s) begin"?. **L**ocation: "Where is the symptom"?. **D**uration: "Is it episodic or constant?" or "How long does it last"?. **C**haracteristics: "How would you describe it?." **A**lleviating and **A**ggravating factors: "What makes it better or worse?." **R**elieving factors: "What makes it better?." **T**reatments: "Have you tried anything to make it better?." **S**everity: "On a scale of 1–10, with 1 being the lower number, how serious is the symptom?."

. **c.** Children and people with decreased mental capacity or impaired verbal ability should be encouraged to respond to interview questions as best as they can. This communicates support of the patient's autonomy, expression of their needs, and respect for their abilities. The information is then validated with family members or guardians as appropriate.

. **b.** The nursing physical assessment involves the examination of all body systems in a systematic manner, commonly using a head-to-toe format called the review of systems (ROS). This assessment begins at the top of the body with the neurologic system and moves downward.

Diagnosis/Problem Identification

Martin Prescott

Martin, a 46-year-old man, comes to the health clinic for a routine physical examination. During the assessment, he states, “I’ve had problems with constipation and have seen some blood when I wipe myself after a bowel movement. It’s just hemorrhoids, right? Nothing to worry about?”

Antonia Zuccarelli

Antonia is a middle-aged woman newly diagnosed with cancer that is treatable. However, she continually fails to show up for follow-up appointments for both continuing diagnosis and treatment.

Angie Clarkson

Angie, a college sophomore, tearfully reports to her student nurse colleague that she believes she is a

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

survivor of date rape. She had too much to drink at a party and can only remember waking up in a strange room with a guy she just met, unsure if she passed out because of the alcohol or date-rape drugs. A virgin, Angie was sure there was penetration because of blood and semen stains she discovered upon waking. It is now a month later and she has not been able to "get her life together" and move on.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Apply basic principles of diagnostic reasoning to identify actual and potential diagnoses, problems, and issues.
. Explain why it is critical to partner with the patient and family to identify priority actual and potential diagnoses, problems, and issues and strengths.
. Describe two historical uses of the term diagnosis.
. Describe the four steps involved in data interpretation and analysis.
. Develop diagnostic/problem statements using the guidelines presented in this chapter.
. Identify three types of diagnoses.
. Describe means to validate actual and potential diagnoses, problems, and issues.

standard

Diagnosing Problem identification—the second step/phase in the nursing process—begins after the nurse has collected and recorded the patient data. The purposes of **diagnosing/analyzing** are to (1) identify how a person, group, or community responds to actual or potential health and life processes; (2) identify factors that contribute to or cause health problems (etiologies); and (3) identify resources or strengths that the person, group, or community can draw on to prevent or resolve problems. See the accompanying Reflective Practice display for an example.

In the diagnosing phase of the nursing process, the nurse interprets and analyzes data gathered from the nursing assessment (Fig. 16-1). Some refer to this phase of the process as analysis. Recall Figure 15-9 in the preceding chapter. The data help the nurse identify patient strengths and health problems. A **health problem** is a condition that necessitates intervention to prevent or resolve disease or illness or to promote coping and wellness.

Alfaro-LeFevre (2014, p. 92) counsels nurses to understand the types of problems they should focus on to better understand their responsibilities relating to the diagnosis and management of health problems. She lists the following as concerns that are central to your role as a nurse:

- Recognizing safety and infection transmission risks and addressing these immediately
- Identifying human responses—how problems, signs and symptoms, and treatment regimens *affect patients' lives*—and promoting optimum function, independence, and quality of life
- Anticipating possible complications and taking steps to prevent them

- Initiating urgent interventions—you do not want to wait to make a final diagnosis if there are signs and symptoms indicating the need for immediate treatment

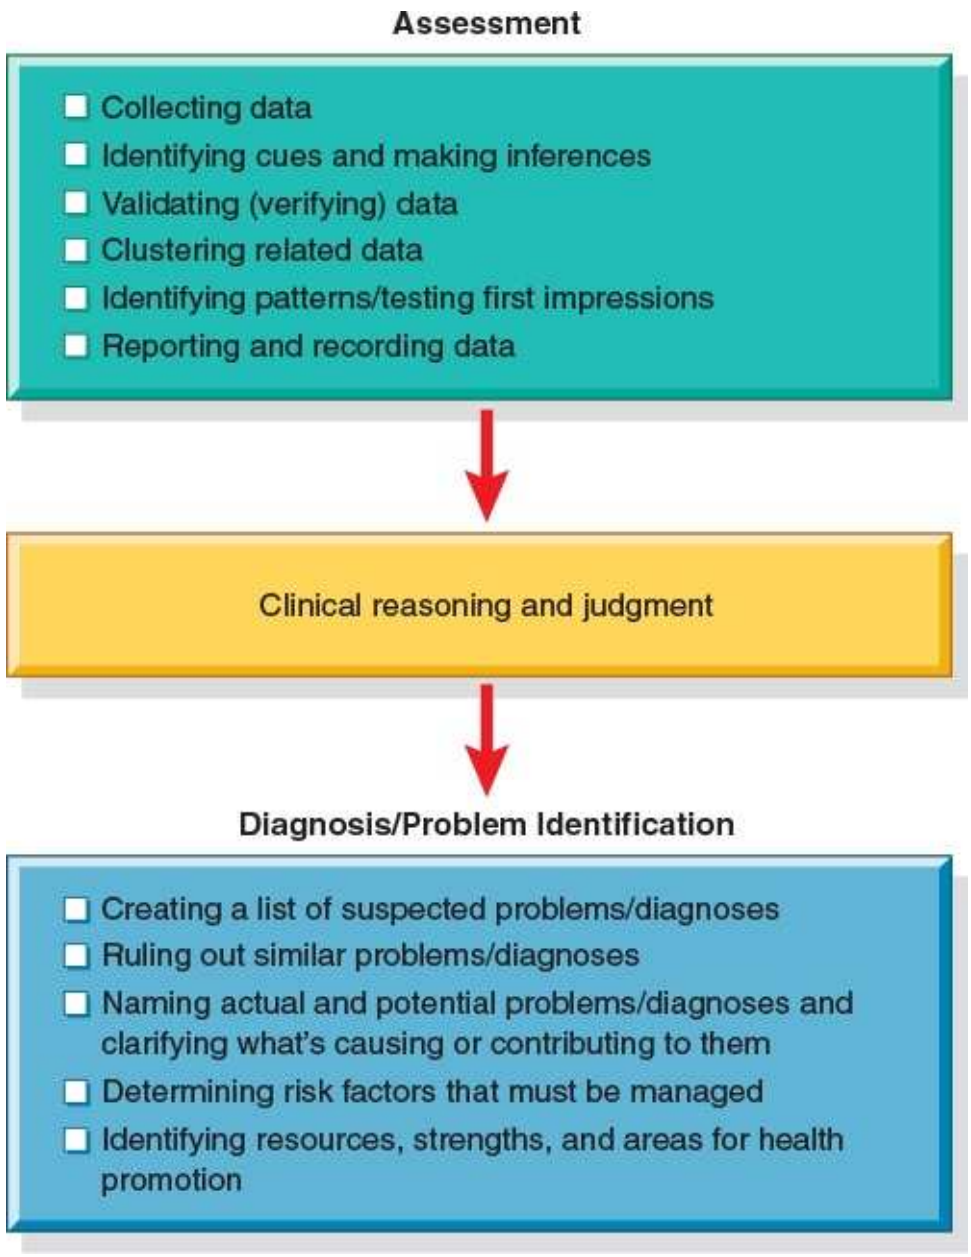

FIGURE 16-1. This diagram shows how the activities of assessment lead to a pivotal point in the nursing process: diagnosis. Diagnosis is a pivotal point for the following reasons: (1) The purpose of diagnosis is to clarify the exact nature of the problems and risks that must be addressed to achieve the overall expected outcomes of care. If you do not completely understand the problems and what factors are contributing to them, how do you know what to do about them? If you don't pay attention to risks, how are you going to prevent problems? (2) The conclusions you make during this phase affect the entire care plan. If your conclusions are correct, your plan is likely to be on target. If they are not—for example, if you are operating on assumptions rather than sound reasoning that is based on evidence—your plan is likely to be flawed, maybe even dangerous. (*Source:* Used with permission from Alfaro-LeFevre, R. [2014]. *Applying nursing process: The foundation for clinical reasoning* [8th ed.]. Wolters Kluwer Health/Lippincott Williams & Wilkins.)

When a health problem is identified, the nurse must decide which health care professional can best address the problem. Actual or potential health problems that can be prevented or resolved by independent nursing intervention have historically been termed **nursing diagnoses**. The nurse formulates, validates, and lists actual or potential problems for each patient (Fig. 16-2 on page 432). These problem statements provide the basis for selecting nursing interventions that will achieve valued patient outcomes for which the nurse is responsible. See the Legal Alert box for Alfaro's rule about the legal implications of diagnoses (Alfaro-LeFevre, 2014, p. 92).

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO COGNITIVE AND INTERPERSONAL SKILLS

Angie Clarkson, a college sophomore, told me, her college friend, tearfully that she believes she is a survivor of date rape her first week in school. She knows she had too much to drink at a party and can only remember waking up in a strange room with a guy she met at the party. She is not sure if she passed out because of the alcohol or if one of the date-rape drugs was involved. A virgin, Angie was sure there had been penetration because of the blood and semen stains she discovered upon waking. It is now a month later and she has not been able to "get her life together" and move on. Angie told me that I am the first person she has told because she feels "so ashamed" and can't believe she let this happen to her. This is my first encounter with an experience like this. I don't do drugs or alcohol and am not sexually active.

Thinking Outside the Box: Possible Courses of Action

- Try to be a good friend and simply suggest she get professional help.
- Advocate for Angie by finding out what resources exist on campus.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Inform Angie that everything she is describing sounds like a significant health problem and explain how to get professional help and why getting help is so important.

Evaluating a Good Outcome: How Do I Define Success?

- Angie gets the professional help she needs to survive this well.
- I prove worthy of her trust in me.
- I use this experience to learn more about a common problem on campus and the adequacy of existing resources.
- I learn something about my ability to diagnose a health problem and plan accordingly.

Personal Learning: Here's to the Future!

Responding to Angie's clear cry for help certainly moved me out of my comfort zone and made me aware of how my newly developing clinical skills will at times complicate something as simple as being a friend. I felt somewhat responsible for helping Angie cope with being raped and believed that I had to do more than simply provide a listening ear. I was pleasantly surprised to discover all the resources that exist on campus. I guess I wasn't surprised that it took quite a bit of coaxing to get Angie to seek professional help. When I showed her some of what is written about the challenges of moving beyond date rape, she seemed to find her experience validated and finally agreed to try the student health service counseling center. I felt positive about my role in helping to make this happen.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your personal attributes and competencies for professional practice? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Clarkson?

Patient-Centered Care: How would you develop a partnership with Ms. Clarkson, knowing her fears? How can you communicate to her that she is your care priority and that she can trust you?

Teamwork and Collaboration/Quality Improvement: *In this case, your teamwork will involve campus resources.* What communication skills do you need to improve to ensure that you can access these resources and make them work for Ms. Clarkson? If your research revealed inadequate campus resources, what could you do to advocate for improved quality?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" in a situation like this? Can you think of campus activities that would promote enhanced safety for all students?

Informatics: Can you identify electronic resources that might help Ms. Clarkson or you? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Legal Alert

The term *diagnosis* implies that there's a situation or problem requiring appropriate, qualified treatment. This means that if you identify a problem, you must decide if you are *qualified* to treat it and willing to *accept responsibility* for treating it. If you are not, you are responsible for getting help.

Alfaro recommends using both a nursing model and a body systems approach (see Chapter 15) to organize assessment data to detect both nursing and medical problems.

Today you can find literature on both nursing diagnosis care plans and problem-based care plans. In this chapter, we will continue to teach you what a nursing diagnosis is and how to write these statements, which many nursing programs require. We will also teach you how to identify and write actual and potential problem statements, which you will increasingly use in your practice sites. This text selects examples of patient problems from Lippincott Advisor (2020) and the International Council of Nurses International Classification for Nursing Practice (ICNP) Nursing Diagnosis and Outcome Statements (2019) lists.

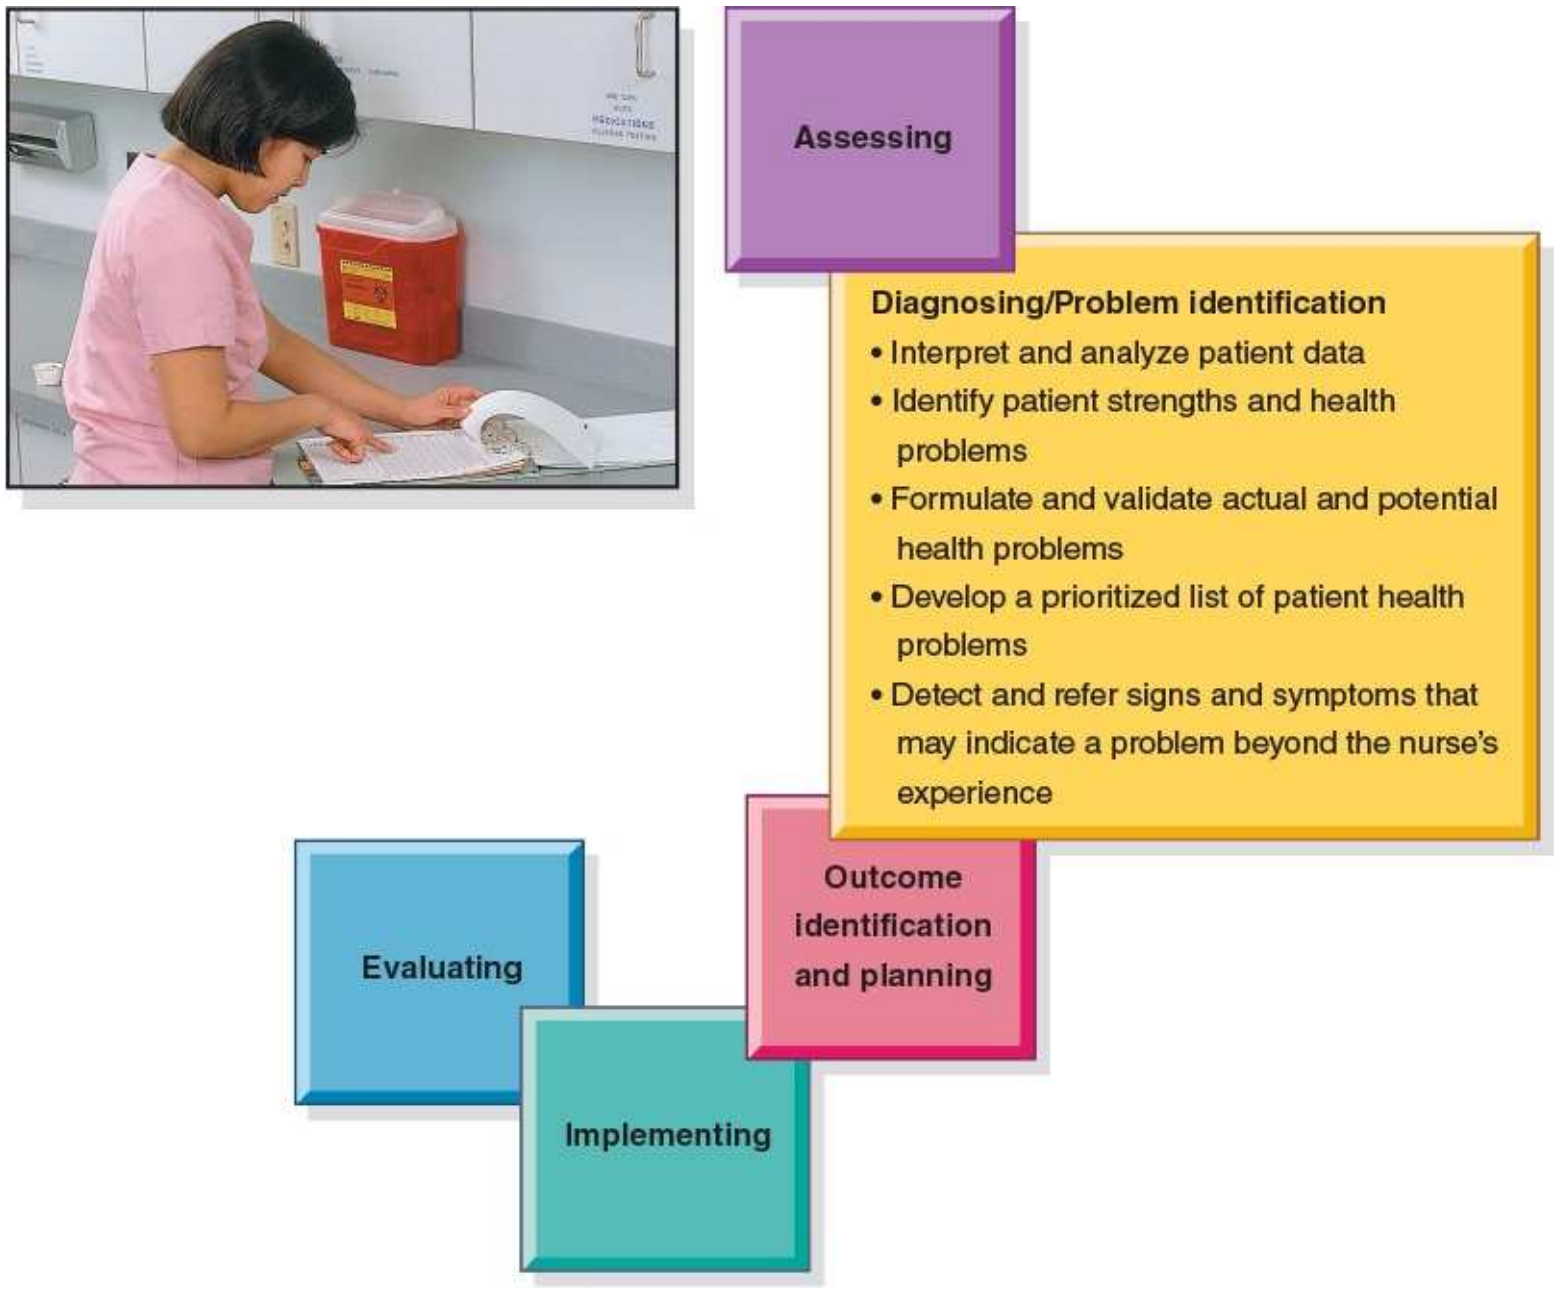

FIGURE 16-2. Diagnosing is the interpretation and analysis of patient data to identify patient strengths and health problems that nursing intervention can prevent or resolve. Patient problems may change from day to day as the patient's responses to health and illness change. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

EVOLUTION OF NURSING DIAGNOSIS

The term *nursing diagnosis* first appeared in the literature in the 1950s. As early as 1966, Hammond wrote that nurses need to be competent in information-seeking strategies and should have a good background of theoretical knowledge to search for cues and evaluate evidence. These skills and knowledge result in accurate diagnosing.

Key milestones in the evolution of nursing diagnosis as an integral component of the nursing process include the following:

- **1953:** The term *nursing diagnosis* was introduced by Fry (1953) to describe a step necessary in developing a care plan.
- **1972:** The New York State Nurse Practice Act identified diagnosing as part of the legal domain of professional nursing; practice acts in many other states have been revised similarly since then.
- **1973:** The American Nurses Association's Standards of Practice included diagnosing as a function of professional nursing.
- **1973:** Kristine Gebbie and Mary Ann Lavin, of St. Louis University, called the First National Conference on the Classification of Nursing Diagnoses, beginning a national effort to identify, standardize, and classify health problems treated by nurses. At this first meeting, the National Group, since renamed the North American Nursing Diagnosis Association (NANDA) and subsequently renamed NANDA International (NANDA-I), appointed a task force to accomplish the following goals:
- Gather information and disseminate it through the Clearinghouse for Nursing Diagnosis.
- Encourage educational activities at regional and state levels to promote the implementation of nursing diagnoses. These activities include conferences to organize nurses to identify additional diagnostic labels and workshops to teach nurses about nursing diagnoses.
- Promote and organize activities to continue the development, classification, and scientific testing of nursing diagnoses. These activities include planning national conferences, identifying criteria for accepting diagnoses, surveying current research activities, and exploring varied methods for classification.
- **1980:** The American Nurses Association (ANA) Social Policy Statement defined nursing as "the diagnosis and treatment of human response to actual or potential health problems" (ANA, 1980).
- **March 1990:** At the Ninth Conference of NANDA, the General Assembly approved an official definition of nursing diagnosis:

Nursing diagnosis is a clinical judgment about individual, family, or community responses to actual or potential health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

problems/life processes. Nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable (NANDA, 1990).

- **March 1990:** The first issue of *Nursing Diagnosis*, NANDA's official journal, was published.
- **2004:** The ANA Standards of Nursing Practice revised the Standard 2 Diagnosis, to include the word *issues:* "The registered nurse analyzes the assessment data to determine the diagnoses or issues." In 2015, the ANA Standards of Practice read: "The registered nurse analyzes assessment data to determine actual or potential diagnoses, problems, or issues" (p. 55) (Box 16-1). Adding "issues" to the standard reflects the realities of today's health care setting. Today's nurses deal with specific problems (diagnoses) and ill-defined problems (issues).
- **2015:** The National Academy of Medicine (NAM)'s report (2015), *Improving Diagnosis Healthcare*, highlighted the catastrophic impact of diagnostic errors and designated eight specific goals to address the problem. The first two goals are relevant to nursing education (Gleason et al., 2021):
  - Goal 1: Facilitate more effective teamwork in the diagnostic process among health care professionals, patients, and their families.
  - Goal 2: Enhance health care professional education and training in the diagnostic process.

Box 16-1 Checklist for Identifying Actual and Potential Problems

1. List current medications (include over-the-counter and herbal drugs). Ask yourself whether any of the patients or problems could be related to any of the medications (remember SODA).
   Side effect?
   Overdose?
   Drug interaction?
   Allergy or adverse reaction?
2. List current and past allergies, diseases, surgeries, or trauma.
3. Consider whether any of the patient's current problems are related to questions 1 or 2 above.
4. Complete the following checklist:
   (Circle those that apply)

Is there a problem with breathing?	Yes	No	AR[1]	Pos[2]
Is there a problem with circulation?	Yes	No	AR	Pos
Is there a problem with comfort?	Yes	No	AR	Pos
Is there a problem with nutrition?	Yes	No	AR	Pos
Is there a problem with urinary or bowel illumination?	Yes	No	AR	Pos
Is there a problem with fluid or electrolyte balance?	Yes	No	AR	Pos
Is there a problem with ability to think or perceive environment?	Yes	No	AR	Pos
Is there a problem with communication?	Yes	No	AR	Pos
Is there a problem with safety (risk for injury or falls)?	Yes	No	AR	Pos
Is there a problem with sleeping or exercising?	Yes	No	AR	Pos
Is there a risk for infection (self or transition to others)?	Yes	No	AR	Pos
Is there a risk for impaired skin integrity?	Yes	No	AR	Pos
Is there a psychological development of self-esteem problem?	Yes	No	AR	Pos
Is there a sociocultural problem?	Yes	No	AR	Pos
Is there a problem with roles, relationships, or sexuality?	Yes	No	AR	Pos
Does the person have a problem with taking medications?	Yes	No	AR	Pos
Does the patient require teaching?	Yes	No	AR	Pos
Is there a problem with health maintenance at home?	Yes	No	AR	Pos
Is this admission going to cause difficulties at home?	Yes	No	AR	Pos
Is there a problem with personal or religious beliefs?	Yes	No	AR	Pos
Is there a problem with coping or managing stress?	Yes	No	AR	Pos
Could this person be pregnant?	Yes	No	AR	Pos

[1]AR = At risk for problem (no signs and symptoms present, but risk factors are evident).
[2]Pos = Possible problem (insufficient data, but you suspect a problem).
Source: © 2018 R. Alfaro-LeFevre. www.AlfaroTeachSmart.com

- 2021: *The Essentials: Core competencies for professional nursing education* articulates as a basic competency for entry-level professional nursing education: "Diagnose actual or potential health problems and needs." This is further specified as:
- Synthesize assessment data in the context of the individual's current preferences, situation, and experience.
- Create a list of problems/health concerns.
- Prioritize problems/health concerns.

- Understand and apply the results of social screening, psychological testing, laboratory data, imaging studies, and other diagnostic tests in actions and plans of care.
- Contribute as a team member to the formation and improvement of diagnoses (p. 32).
- 2021: The *ANA Scope and Standards of Practice* (4th ed.) includes the competency, "Uses assessment data, standardized classification systems, technology, and clinical decision support tools to articulate actual or potential diagnoses, problems, and issues." Note that ANA defines the outcomes of diagnosing as "diagnoses, problems, and issues." This language will be used throughout this chapter.

Now an accepted and essential phase in the nursing process, nursing diagnosis was initially confused with medical diagnosis, sparking controversy. *Medical* diagnosis refers to a provider's assignment of a syndrome or disease label to a set of signs, symptoms, and other findings. In contrast, *nursing* diagnosis is a "clinical judgment concerning a human response to health conditions and/or life processes, or a vulnerability for that response, by an individual, family, group, or community. A nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse has accountability" (Herdman & Kamitsuru, 2018).

Although the confusion between medical and nursing diagnoses has been resolved, many nurses have been slow to understand and to accept the "work" of diagnosing. Gleason et al. (2021) underscore the critical importance of nurses being part of the diagnostic team if we are to aggressively confront the problem of diagnostic error:

> … we believe nurses are essential members of the diagnostic team and should enter practice with the expectation to participate actively and meaningfully in the diagnostic process, and that nursing education should prepare them to assume this responsibility and accountability (p. 363).

UNIQUE FOCUS OF DIAGNOSING

In the diagnosing phase of the nursing process, the nurse expresses nursing's unique concern for a patient by analyzing patient data to identify each patient's unique actual and potential health problems and needs. This may lead to diagnosing a problem that nurses can independently treat or a problem best treated collaboratively by the interprofessional team.

Consider **Antonia Zuccarelli**, the middle-aged woman recently diagnosed with cancer but failing to maintain follow-up. Although the patient's diagnosis of cancer is important, the nurse would focus on the patient's lack of follow-up and the possible underlying reasons. For example, the patient may not realize the importance of the follow-up, thereby indicating a lack of knowledge. Or the patient may be too overwhelmed with the diagnosis, possibly denying its existence and being unable to cope.

Alfaro-LeFevre (2014, pp. 93–94) describes the shift from diagnose and treat (DT) to predict, prevent, manage, and promote (PPMP). The latter approach focuses on early evidence-based intervention to prevent and manage problems and their potential complications. It requires three activities for nurses:

. In the presence of known problems, predict the most common and most dangerous complications and take immediate action to (a) prevent them, and (b) manage them in case they cannot be prevented.
. Whether problems are present or not, look for evidence of risk factors (things that evidence suggests contribute to health problems). If you identify risk factors, you aim to reduce or control them, thereby preventing the problems themselves.
. In all situations, ensure that safety and learning needs are met, and promote optimum function and independence.

As nurses interpret and analyze patient data, they may identify health problems that are better treated by physicians (medical diagnoses) or by nurses working with other health care professionals (collaborative problems). In such a case, the nurse reports the findings to the physician or other appropriate health care professionals and works collaboratively with them to resolve the problem. Gleason et al. (2021) are quick to note that nurses working in highly medicalized environments are expected to identify and intervene in a wide range of medical diagnoses, including life-threatening conditions such as stroke, pulmonary embolism, and sepsis.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Patient Problems Versus Medical Diagnoses

Medical diagnoses identify diseases, whereas problem statements focus on unhealthy responses to health and illness. Medical diagnoses describe problems for which the physician or advanced practice nurse directs the primary treatment. A medical diagnosis remains the same for as long as the disease is present, whereas patient problems may change from day to day as the patient's responses change. These distinctions reflect key differences in medical and nursing practices.

Myocardial infarction (heart attack) is a medical diagnosis. Examples of patient problems for a person with myocardial infarction may include Acute anxiety, Activity intolerance, Knowledge deficiency, Acute pain, Altered tissue perfusion, Coping impairment, and Death anxiety (Lippincott Advisor, 2020).

Table 16-1 A Comparison: Nursing Diagnosis and Medical Diagnosis

	NURSING DIAGNOSIS	MEDICAL DIAGNOSIS
Definition	A nursing diagnosis is a clinical judgment about individual, family, or community responses to actual or potential health problems or life processes. Nursing diagnosis provides the basis for selection of nursing interventions to achieve outcomes for which the nurse is accountable (NANDA-I).	Traumatic or disease condition or syndrome validated by medical diagnostic studies
Focus	Monitoring human responses to actual and potential health problems	Correcting or preventing pathology of specific organs or body systems
Sample data cluster	56-year-old mother of seven; 5 ft 4 in, 167 lb; "Whenever I sneeze lately, I dribble urine. This is embarrassing."	22-year-old woman; "Whenever I have to urinate, it burns terribly. I also feel like I have to go all the time—real bad." Small, frequent voidings, cloudy urine; T—100.8°F
Problem statement	Stress Incontinence of Urine; etiology, degenerative changes in pelvic muscles and structural supports associated with advanced age, obesity, gravid uterus	Cystitis
Select nursing responses	Teach Kegel exercises to increase muscle tone; explore patient's willingness and motivation to pursue weight reduction and exercise program; evaluate need for bladder-training program.	Report signs and symptoms to physician; obtain urine culture; report results to physician; administer appropriate physician-prescribed antibiotic.

Think back to **Angie Clarkson**, the college sophomore who was a victim of date rape. Possible nursing diagnoses might include Rape Trauma Response (ICNP, 2019), Coping impairment, Situational low self-esteem, and Infection risk (Lippincott Advisor, 2020).

Table 16-1 shows how health care professionals successfully interpret different clusters of data to identify a patient problem and a medical diagnosis. In the first example, a patient problem is identified and successfully treated. In the second example, the nurse's early detection and reporting of the problem to the health care provider led to the health care provider's prompt medical diagnosis of cystitis and successful antibiotic therapy.

DIAGNOSTIC REASONING, CLINICAL REASONING, AND CLINICAL JUDGMENT

Successful implementation of each phase of the nursing process requires high-level skills in clinical reasoning and judgment. To correctly diagnose health problems:

- Be familiar with lists of actual and potential health problems and needs (see Lippincott Advisor and ICNP, 2020 and 2019), read professional literature, and keep reference guides handy.
- Trust clinical experience and judgment but be willing to ask for help when the situation demands more than your qualifications and experience can provide.
- Respect your clinical intuition, but before writing a problem statement without evidence, increase the frequency of your observations and continue to search for cues to verify your intuition.
- Recognize personal biases and keep an open mind.

Questions to facilitate clinical reasoning and judgment during diagnostic reasoning include the following:

- Are my data accurate and complete? Do the objective data support the subjective data? How do I know that this information is reliable?
- Have I correctly distinguished normal from abnormal findings for this patient and decided if abnormal data may be signs and symptoms of a specific health problem?
- Have I made and validated deductions or opinions that follow logically from patient cues?
- Has the patient or the patient's surrogates validated (if able to do so) that these are important problems?
- Have I given the patient or the patient's surrogate an opportunity to identify problems that I may have missed?
- Is each problem statement supported by evidence? Might these cues signify a different problem?
- Have I tried to identify what is causing the actual or potential problem, and what strengths/resources (including but not limited to support systems, health literacy, and engagement in self-care) the patient might use to avoid or resolve the problem?
- Have I followed facility guidelines to correctly document problem statements in a way that clearly communicates patient problems to other health care professionals?
- Have I documented diagnoses, problems, strengths, and issues in a manner that facilitates the development of the expected outcomes and collaborative plan (ANA, 2021, p. 78)?

Gleason et al. (2017) counsel nurses, if what you are observing in a patient does not align with an assigned diagnosis, or if observed changes appear to indicate a new or different diagnosis, this creates an opportunity and an obligation to intervene and mitigate diagnostic errors before there is harm. From your earliest days in clinical practice, you want to cultivate the art of thinking like a nurse, which requires a "flexible and nuanced ability to recognize salient aspects of an undefined clinical situation, interpret their meanings, and respond appropriately" (Tanner, 2006).

DIAGNOSTIC REASONING AND INTERPERSONAL COMPETENCE

Diagnostic statements are best made and used by nurses who have strong interpersonal and communication skills. These skills make it more likely that a patient will be able to trust you sufficiently to talk about their responses to health problems and life processes. You must be able to demonstrate your desire to listen to the patient's narrative to gain trust: "Tell me your story."

The best use of diagnosis/analysis is in partnership with patients, families, groups, and communities. To work in partnership, nurses need to speak to people with respect and care, listen effectively, respect the opinions and views of others, and know how to validate perceptions with patients and families (Skelley et al., 2020); see Figure 16-3. Learning these skills is a challenge, so the interpersonal aspects of nursing need to be an integral part of learning to use the diagnosis/problem identification phase of the nursing process.

DATA INTERPRETATION AND ANALYSIS

Most experienced nurses begin the work of interpreting and analyzing data while they are still collecting (assessing) the data. The term **cue** is often used to denote significant data or data that influence this analysis. Significant data should "raise a red flag" for the nurse, who then looks for patterns or clusters of data that signal an actual or possible health problem.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 16-3. This nurse is using respectful listening to elicit the patient's trust and promote a partnership to identify and prioritize patient problems. (*Source:* Used with permission from Shutterstock. *Photo by Monkey Business Images.*)

Recall **Martin Prescott**, the 46-year-old man with bleeding associated with bowel movements. The report of bleeding accompanied by the patient's complaint of constipation should alert the nurse to a potential problem involving the patient's bowel elimination.

Recognizing Significant Data

Sorting out healthy patient responses from those that are not healthy is not as clear-cut as it may seem. To avoid erroneously labeling selected patient health patterns as unhealthy (**diagnostic error**) while failing to detect an actual unhealthy behavior, nurses must be familiar with comparative standards to be used in data interpretation and analysis.

A **standard**, or a norm, is a generally accepted rule, measure, pattern, or model to which data can be compared in the same class or category. For example, when determining the significance of a patient's blood pressure reading, appropriate standards include normative values for the patient's age group, race, and illness category. The patient's own normal range, if known, is an important standard. A pressure of 150/90 mm Hg may be high for someone whose pressure normally is 120/70 mm Hg, but it may be normal for a person with hypertension. Examples of how standards can be used to identify significant cues include the following (Gordon, 1994):

- Changes in a patient's usual health patterns that are unexplained by expected norms for growth and development: *Example: An infant who took to breastfeeding easily as a newborn suddenly stops sucking when put to the breast and begins to lose weight.*
- Deviation from an appropriate population norm: *Example: A first-year college student begins to accelerate her exercise habits dramatically and starts inducing vomiting after binge eating. She rapidly loses weight.*
- Behavior that is nonproductive in the whole-person context: *Example: A college student breaks up with her boyfriend and begins to believe that she is "unfit" for any other relationship, withdrawing from her friends and social activities.*
- Behavior that indicates a developmental lag or evolving dysfunctional pattern: *Example: A 16-year-old single mother with a 6-month-old infant continues to "party hard" with her friends, hangs out at the mall, and shows no interest in caring for her son, who is repeatedly left with concerned family members.*

Recognizing Patterns or Clusters

A **data cluster** is a grouping of patient data or cues that point to the existence of a health problem. Diagnostic statements should always be derived from clusters of significant data rather than from a single cue. The danger of deriving a nursing diagnosis from a single cue is illustrated in the following example. Diagnosing a woman recovering from gallbladder surgery with a coping impairment solely on the basis of tears may misinterpret the patient's crying, which may be a healthy release of emotion. If the same patient begins to exhibit a cluster of significant cues, such as refusing to eat, preferring bed rest to scheduled ambulation, and reporting increasing discomfort, an unhealthy pattern is emerging.

Think back to **Angie Clarkson**, the college sophomore. Her verbalization of the rape trauma is significant. However, even more significant is Angie's report that the event happened more than 1 month ago, and she is having difficulty "getting her life together" and moving on.

Table 16-2 (on page 438) offers examples of how clusters of significant data lead to formulation of accurate diagnostic statements.

Identifying Strengths and Problems

The next step in analyzing data is to determine the patient's strengths and problems. It also helps to determine whether the patient agrees with the nurse's identification of strengths and problems and is motivated to work toward problem resolution. If you recall the situation described in the Reflective Practice box on p. 431, you'll understand how important it is to create a partnership with the patient and family in order to respect the patient's priorities.

Determining Patient and Family Strengths

If a patient appears to meet a standard, the nurse concludes that the patient has strength in that particular area, and that this strength contributes to the patient's level of wellness. For example, a person with a history of maintaining a well-balanced diet is usually better able to cope with illness than a person who has a history of unhealthy eating.

Patient strengths might include healthy physiologic functioning, emotional health, cognitive abilities, coping skills, interpersonal strengths, and spiritual strengths. Resources such as the presence of support people, adequate finances, and a healthy environment may all contribute to patient strengths. Many people take their strengths for granted and may not know how to use them effectively when responding to illness. Discussing observed strengths with patients and counseling patients about ways to develop and use their strengths are important nursing measures.

Determining the Patient's Problem Areas

A person who does not meet a certain health standard probably has a limitation in that area and may benefit from professional care. For example, a person with a long history of constipation probably needs care to help overcome this problem. If you are preparing to discharge an 80-year-old patient with chronic pulmonary obstructive disease home and realize that they live alone with no one to help them manage their diet, medicines, and new therapies, you need to report their problem areas, or you can be sure you will quickly see them readmitted to the hospital in crisis. Ideally, you will be able to identify community resources that can be accessed to help them successfully transition home. It is always helpful to remember the social determinants of health discussed in Chapter 3. The Patient-Centered Assessment tool in Chapter 15 uses the social determinants of health to explain why some patients engage and respond well in managing their health, while others with the same or similar health condition do not experience the same outcomes and success.

Determining Problems the Patient Is Likely to Experience

Nurses also identify potential health problems. For example, a nurse notes that a patient has signs of a wound infection, but laboratory test results show that the patient's white blood cell count has not increased, as is usual when such an infection is present. The nurse concludes that the body apparently is not building up normal defenses to combat the infection. The nurse then predicts the problems this patient is likely to encounter, such as a longer-than-normal healing period. Potential problems alert other caregivers to problems the patient may experience if certain trends in the patient's condition continue unreversed. This prediction has implications for nursing care, such as the need for measures related to the patient's diet, fluid intake, urine output, and mobility. You will want to be familiar with the common lists of problems endorsed by your school or program. Box 16-1 on page 433 offers a practical checklist for identifying actual and potential problems. You may find it helpful to use this checklist when you first meet your assigned patients. If your practice site uses an electronic medical record, problem lists will be preloaded for your convenience. Figure 16-4 (on page 439) provides a systematic problem analysis worksheet that you may find helpful, especially when doing concept mapping. Alfaro reminds us that diagnosis is incomplete until we identify not only the problems but also the underlying causes and contributing factors of the problems.

Identifying Potential Complications

Patients may experience many complications related to their diagnoses, medications or treatment regimens, or invasive

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

diagnostic studies. While new to nursing, you can more easily prevent potential complications—or at least make sure that they are detected early and managed well—if you research the potential complications associated with your patient's diagnoses, diagnostics, and treatment, and if you report all abnormal data. For example, slurred speech, changes in skin color or moistness, inability to move an extremity or abnormal movement, and changes in levels of consciousness may all be indications of serious and life-threatening complications. Remember, if you are unsure about the significance of data, always confer with someone more experienced.

Table 16-2 Formulating an Accurate Diagnostic Statement Based on Data Clusters

DATA INTERPRETATION AND ANALYSIS		FORMULATION OF TENTATIVE PROBLEM STATEMENT	VALIDATION
Significant Cues	***Sample Data Clusters***		
Patient 1			
Change in a patient's usual health patterns that is unexplained by expected norms for growth and development	• "I guess I lost about 20–30 lb over the last 6 months—I think I've just been too busy to eat." • Height: 5 ft 8 inches • Weight: 102 lb • 35-year-old mother of twin boys; returned to work (executive secretary) for first time since delivery of twins 7 months ago	Malnutrition risk; possible etiologic factors: stress of new job; role conflict and demands	Accurate problem statement: Patient validates this problem, agreeing with contributing factors
Patient 2			
Deviation from an appropriate population norm	• Teacher notices and reports frequency of bruises on third-grade boy who is repeatedly observed alone during recess periods and who is withdrawn in classroom. • In conversation with the school nurse, one of the boy's parents remarks: "That boy brings out the worst in me! I don't know why, but I often have to smack him hard to make him listen."	Risk To Be Victim of Child Abuse	Incomplete problem statement: Additional data collection yields new information: • Father out of work for past 18 months • Father was abused as a child Problem restated: Risk to be a victim of child abuse; possible etiologic factors: increased family stress and father's history of being abused
Patient 3			
Behavior that is nonproductive in the whole-person context	• Fiancé abruptly terminated relationship 3 months before established wedding date • Noticeable change in physical appearance; frequently wears same clothes; makeup, jewelry, hairstyling are absent; strong body odors present	Situational low self-esteem; possible etiologic factor: feeling rejected by fiancé	Premature problem statement resulting from incomplete data collection. Patient has a long history of major depressive states, one of which may have resulted in the breakup of this relationship. Medical diagnosis and treatment indicated.

	• No desire to be with others; goes home (lives alone) immediately after work • Stopped attending aerobics classes		Changes in appearance are indicative of depressive state. Need to explore related problems
Patient 4			
Behavior indicating developmental lags or evolving dysfunctional patterns	• Admitted to long-term care facility 2 months ago • "I have nothing to live for anymore … why don't I die?" • Wishes to remain in room seated in chair; will only ambulate with great urging • Anything requiring movement has become "too much bother" • Decreased muscle mass, tone, and strength; reduced joint mobility	Deconditioning; possible etiologic factor: difficult transition to long-term care facility	Accurate but routinized problem statement that may result in staff's acceptance of status quo unless a more specific cause is identified

SYSTEMATIC PROBLEM ANALYSIS WORKSHEET

Instructions:

1. List the focus problem, diagnosis, or issue in the box below.
2. Put a check mark in all boxes on the right that correspond to factors that contribute to the problem, diagnosis, or issue you identified.
3. Decide what factors must be managed and who will manage them.
4. Use back of page or figure of man as needed.

Actual/potential diagnosis, problem, or issue

CONTRIBUTING OR RELATED (RISK) FACTORS

1. Main reason for admission or contact?

2. Vulnerability—constitutional or age-related factors?

❑ Age ____ Weight ____ Height ____ Mental Status? ____
❑ Communication ability? ❑ Smoker? ❑ Drinker (alcohol)?
❑ Skin status? ❑ Nutrition-hydration status?
❑ Mobility or self-care problems?
❑ Bowel elimination or urine elimination problems?
❑ Immune system status? ❑ Overall health status/resilience?
❑ Other?

3. Allergy, medication, or treatment-related factors?

❑ Allergies? ❑ Considered all meds (Rx, OTC, herbal)?
❑ Treatments?

4. Co-existing medical problems, injuries, or pathophysiology

❑ Neuro? ❑ Resp? ❑ Cardiac-circulatory? ❑ GI? ❑ GU?
❑ Diabetes? ❑ Hypertension? ❑ Depression? ❑ Other?

5. Environmental factors? Patient identified factors?

❑ Current environment (include work)? ❑ Role-related?
❑ Other factors?

6. Comfort factors? Mobility problems? Self-care problems?

❑ Pain level? ❑ Pain management? ❑ Self-mobile? ❑ Other?

7. Socioeconomic, spiritual, cultural factors?

❑ Family issues? ❑ Coping problems? ❑ Support systems limited?
❑ Other?

FIGURE 16-4. Systematic problem analysis worksheet. (*Source:* Used with permission. Alfaro-LeFevre, R. [2020]. *Critical thinking,*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

clinical reasoning, and clinical judgment [7th ed.]. Elsevier, p. 162.)

Reaching Conclusions

The nurse reaches one of three basic conclusions after interpreting and analyzing the patient data. Different nursing responses result from each conclusion:

No Problem

- No nursing response is indicated.
- Reinforce the patient's health habits and patterns.
- Initiate health promotion activities to prevent disease or illness or to promote a higher level of wellness.
- Wellness diagnosis might be indicated.

Possible Problem

- Collect more data to confirm or disprove a suspected problem.

Actual or Potential Diagnosis, Problem, or Issue

- Document the diagnosis, problem, or issue.
- Begin planning, implementing, and evaluating care designed to prevent, reduce, or resolve the problem.
- Consult with the appropriate health care professionals and work collaboratively on the problem as indicated.
- If unable to treat the problem because the patient denies the problem and refuses treatment, make sure that the patient understands the possible outcomes of this stance.

Partnering With the Patient and Family

Remember that your best source of information usually is an aware patient. Although some patients still enter the health care system expecting physicians and nurses to tell them what is "wrong" and to "fix it," increasingly patients want to play a leading role in identifying and treating their health problems.

Concept Mastery Alert

Be sure to ask patients what they believe their most important problems or issues are and have them confirm what your assessment reveals and helps you prioritize the resulting list of diagnoses/problems.

FORMULATING AND VALIDATING NURSING DIAGNOSES AND PROBLEM STATEMENTS

Terminology for Writing NANDA-I Approved *Nursing* Diagnoses

When the nurse recognizes a cluster of significant patient data indicating a health problem that can be treated by independent nursing interventions, a *nursing* diagnosis should be written. If you are just beginning to understand and write nursing diagnoses, consult the list of health problems accepted by NANDA-I for testing and study (https://www.nanda.org/). The NANDA-I list is a beginning list of suggested terms for health problems that might be identified and treated by nurses. Each of the diagnoses in *NANDA International Nursing Diagnoses: Definitions and Classification, 2018–2020* is presented in taxonomic order and includes the basic components of a nursing diagnosis: definition and defining characteristics.

There are distinct advantages to nurses' use of common terminology when formulating nursing diagnoses. These range from communication advantages (everyone uses the same words to describe common problems) to promoting the development of nursing science by facilitating research and the dissemination of research findings to establishing the foundation for any cost–benefit analysis for nursing practice. Pocket-sized handbooks of NANDA-I–approved nursing diagnoses are available and should help students unfamiliar with this grouping of health problems.

Types of *Nursing* Diagnoses

There are basically three types of nursing diagnoses: problem focused, risk, and health promotion.

A **problem-focused nursing diagnosis** is a clinical judgment concerning an undesirable human response to a health condition/life process that exists in an individual, family, group, or community. A **risk nursing diagnosis** is a clinical judgment concerning the vulnerability of an individual, family, group, or community for developing an undesirable human response to health conditions/life processes. A **health promotion nursing diagnosis** is a clinical judgment concerning motivation and desire to increase well-being and to actualize human health potential. These responses are expressed by a readiness to enhance specific health behaviors and can be used in any health state. Health promotion responses may exist in an individual, family, group, or community.

Table 16-3 Formulating Problem Statements

	DEFINITION	PURPOSE	EXAMPLE

Problem	Identifies what is unhealthy about the patient, indicating the need for change (clear, concise statement of the patient's health problem)	Suggests the patient outcomes (expectations for change)	Activities of daily living (ADL) deficit ↓
Etiology	Identifies the factors that are maintaining the unhealthy state or response (contributing or causative factors)	Suggests the appropriate nursing measures	Fear of falling in the tub and obesity ↓ ↓
Signs and Symptoms	Identify the subjective and objective data that signal the existence of the problem (cues that reflect the existence of a problem)	Suggest evaluative criteria	Strong body and urine odor, unclean hair: "I'm afraid I'll fall in the tub and break something." (5 ft 4 inches, 170 lb)
Examples: Two-part diagnostic statement: ADL deficit; possible etiologic factors: fear of falling in tub and obesity Three-part diagnostic statement: ADL deficit; possible etiologic factors: fear of falling in tub and obesity; signs and symptoms: strong body and urine odor, unclean hair, statement of fearing fall in tub, and height and weight: 5 ft 4 inches, 170 lb			

Terminology for Writing Problem Statements

Most diagnostic statements are written either as two-part statements listing the patient's problem and its cause (etiology) or as three-part statements that also include the problem's signs and symptoms (Table 16-3). You will find examples of three-part diagnoses/patient problems in every clinical chapter.

Concept Mastery Alert

The acronyms PE and PES can be helpful in remembering how to write a nursing diagnosis. PE stands for "problem" and "etiology"; PES stands for "problem," "etiology," and "signs and symptoms."

Problem

The purpose of the problem statement is to describe the health state or health problem of the patient as clearly and concisely as possible. Because this section of the nursing diagnosis identifies what is unhealthy about the patient and what the patient would like to change in their health status, it suggests patient outcomes. Quantifiers or descriptors may be used to limit or specify the meaning of a problem statement. For example, the descriptor "anticipatory" placed before the concept "grieving" clarifies the diagnosis for a pregnant couple informed prenatally that their child will most likely be stillborn and who are already grieving the death of their child. Some common descriptors include terms such as decreased, dysfunctional, impaired, ineffective, or situational.

Lippincott Advisor (https://advisor.lww.com/lna/turnaway.do) uses the following headings under problem-based care plans:

Activity and Rest
Behavioral Health
Cognition
Comfort
Elimination
Health Promotion
Nutrition
Patient Safety
Roles and Relationships
Skin and Wounds
Ventilation and Perfusion

When expanded, each heading identifies related problems; for example, under Activity and Rest, common problems

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

are: Activity intolerance

ADL deficit
Bathing/hygiene ADL deficit
Deconditioning
Discharge planning
Dressing ADL deficit
Fatigue
Sleep deprivation

ETIOLOGY

The etiology identifies the physiologic, psychological, sociologic, spiritual, and environmental factors believed to be related to the problem as either a cause or a contributing factor. Because the etiology identifies the factors that maintain the unhealthy patient state and prevent the desired change, the etiology directs nursing intervention. Unless the etiology is correctly identified, nursing actions might be inefficient and ineffective. For example, a patient with diabetes who is frequently admitted to the hospital with hyperglycemia and who has a poor history of dietary and pharmacologic management is diagnosed to be nonadherent. Mistakenly assuming that the nonadherence is related to a knowledge deficit, the nurse channels all nursing activities and energies into teaching the patient how to manage the diabetes. However, this would be useless if the nonadherence were actually a result of the patient's decreased will to live, an etiology that would necessitate a different group of nursing interventions.

SIGNS AND SYMPTOMS

The subjective and objective data that signal the existence of the actual or potential health problem are the third component of the nursing diagnosis. It is important to remember that the signs and symptoms are part of assessment. Although they are written last in the formal problem statement, they are considered first. Table 16-3 defines the components of a diagnosis/problem statement and shows how they affect patient outcomes, nursing measures, and evaluation.

Guidelines for Writing Diagnostic Statements

Remember these guidelines to ensure that your diagnostic statements are correctly written.

. Phrase the diagnostic statement as an actual or potential diagnosis, problem, or issue.
. Check to make sure that the patient problem precedes the etiology.
. Consider when at-risk populations or associated conditions should be identified.
. Signs and symptoms, when included in the nursing diagnosis, should follow the etiology.
. Write in legally advisable terms.
. Use nonjudgmental language.
. Be sure the problem statement indicates what is unhealthy about the patient or what the patient wants to change (enhance).
. Avoid using defining characteristics, medical diagnoses, or something that cannot be changed in the problem statement.
. Reread the diagnosis to make sure that the problem statement suggests patient outcomes and that the etiology will direct the selection of nursing measures.

Common errors in writing diagnostic statements are shown in Table 16-4 (on p. 442), along with suggestions for correcting them.

When recording problems in electronic health records (EHRs), remember that different EHRs organize data differently, and that the documentation for nursing assessments and for nursing diagnoses/problems/issues may vary. Be sure to check your facility's policies. You should be able to select your diagnostic statement within the system's problem list, and the problem list may trigger a message to place an order for an intervention or care set of orders for the patient if this is not already present.

What Is *Not* a Diagnostic Statement

The diagnostic statement is written in terms of a patient problem, alteration in health state, or patient strength, which guides nurses and others to select interventions to achieve valued outcomes. Table 16-5 (on page 443) uses a patient with diabetes mellitus to illustrate what nursing diagnostic statements are not.

Validating Diagnostic Statements

After a tentative diagnostic statement is formulated, it should be validated. An affirmative response to each of the following questions validates a tentative diagnostic statement:

- Is my patient database (assessment data) sufficient, accurate, and supported by nursing research?
- Does my synthesis of data (significant cues) demonstrate the existence of a pattern?

- Are the subjective and objective data I used for determining the existence of a pattern characteristic of the health problem I defined?
- Is my tentative problem statement based on scientific nursing knowledge and clinical expertise?
- Is my degree of confidence above 50%, that other qualified practitioners would formulate the same statement based on my data?

Remember that you are responsible for validating the problem statements you write, even when using computer-assisted problem lists. The use of standardized language and EHRs may make diagnosis writing easier by suggesting possible diagnoses/problems to match your recorded assessment findings. However, computers cannot replace humans and critical thinking, especially when it comes to complex diagnostic reasoning. While the computer can process data faster than you can, it will not be aware of what is happening to your patient at this moment in time. You need to validate your diagnostic statements and recognize when your computer is making an obvious error.

Table 16-4 Common Errors in Writing Nursing Diagnoses and Recommended Corrections

ERROR	EXAMPLE	CORRECTION	EXAMPLE
Writing the diagnosis in terms of needs and not response	Needs assistance with bathing related to bed rest	Write the diagnosis in terms of response rather than need.	Bathing self-care deficit related to immobility
Making legally inadvisable statements	Nonadherence due to hostility toward nursing staff (the words *due to* imply a direct cause-and-effect relationship) Spouse abuse related to husband's immaturity and violent temper Impaired skin integrity related to patient's lying on back all night	Use "related to" rather than "due to" or "caused by" to link the etiology to the problem statement. Write diagnosis in legally advisable terms: statements that may be interpreted as libel or that imply nursing negligence are legally hazardous to all the nurses caring for the patient.	Nonadherence related to hostility toward nursing staff (denotes a relation between the problem and etiology but not necessarily a causal relation) Risk for Violence: Spouse abuse; signs and symptoms: husband's reported inability to control behavior Impaired Skin Integrity related to mobility deficit
Identifying as a problem a patient response that is not necessarily unhealthy	Mild anxiety related to impending surgery	Include in the problem statement of the nursing diagnosis only patient responses that are unhealthy or that the patient wants to change.	No need for nursing diagnosis: mild anxiety before surgery is a healthy response that motivates preoperative self-care behavior
Identifying as a problem signs and symptoms of illness	Cough related to long history of smoking	Avoid including signs and symptoms of illness in the problem statement of the nursing diagnosis.	Ineffective airway clearance related to 20-year history of smoking
Identifying as a patient problem or etiology what cannot be changed	Alterations in bowel elimination: Permanent colostomy related to cancer of bowel Grieving related to death of spouse	Express the problem statement and etiologic factors in terms that can be changed; otherwise, nursing energies are being directed to a hopeless task.	Self-Care Deficit: Care of colostomy, related to severe anxiety about cancer and feelings of powerlessness Dysfunctional Grief related to inability to accept death of spouse
Identifying environmental factors rather than patient factors as a	Cluttered home related to inability to discard anything	Express the problem statement in terms of unhealthy patient	Injury risk; signs and symptoms: cluttered home (inability to

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

problem		responses rather than environmental conditions.	discard anything)
Reversing clauses	Deficient knowledge related to alteration in parenting	Avoid reversing the problem statement and etiologic statement.	Impaired Parenting related to knowledge deficit: child growth and development, discipline
Having both clauses say the same thing	Impaired comfort related to pain (pain is the comfort alteration; what is contributing to the pain?)	Be sure that the two parts of the diagnosis do not mean the same thing.	Unrelieved incisional pain; etiology: fear of addiction
Including value judgments in the nursing diagnosis	Poor home maintenance related to laziness	Write the diagnosis without value judgments; avoid words such as *poor, inadequate, abnormal, unhealthy.*	Impaired Homemaking related to low value ascribed to home safety and cleanliness
Including the medical diagnosis in the diagnostic statement	Impaired home maintenance related to arthritis	Do not include the medical diagnosis in the nursing diagnosis statement.	Impaired Homemaking related to mobility, endurance, and comfort alterations

Common errors adapted from Mundinger, M. O., & Jauron, G. D. (1975). *Developing a nursing diagnosis. Nursing Outlook*, *23*(2), 94–98. Guidelines for writing nursing diagnoses adapted from Iyer, P., Taptich, B., & Bernocchi-Losey, D. (1991). *Nursing process and nursing diagnoses* (2nd ed.). W. B. Saunders.

Table 16-5 What a Nursing Diagnostic Statement Is *Not*, and Why

WHAT A NURSING DIAGNOSTIC STATEMENT IS *NOT*	EXAMPLE	RATIONALE
Medical diagnosis	Diabetes mellitus	Although there is nursing care associated with medical illnesses, the illness is not primarily amenable to nursing intervention. Nursing's concern is the *person* who has the illness and the effect of the illness on human functioning.
Medical pathology	Hypoglycemia	Nurses need to understand the pathology underlying disease states to plan appropriate nursing care, but once again, nursing's focus is the person, not the pathology. The person's response to hypoglycemia, how hypoglycemia affects human functioning—these are the domain of *nursing*.
Diagnostic tests, treatments, equipment	Fasting blood glucose Insulin therapy Insulin syringe Infusion pump	Nursing's concern is the person's response to the diagnostic study, treatment, or equipment. If the need for insulin therapy reveals a deficient knowledge or self-care deficit, this becomes the diagnostic, not insulin therapy in and of itself.
Therapeutic patient needs	Needs to learn the relation among diet, exercise, and insulin	The problem should be written as a patient health problem rather than a patient need. *Example:* Altered health

		maintenance (diabetic care); possible etiologic factor: lack of knowledge of relation among diet, exercise, and insulin.
Therapeutic nursing goals	To develop therapeutic diabetic self-care behaviors	The problem should be written from the patient perspective rather than the nursing perspective and phrased as a patient health problem. *Example:* Activities of daily living deficit: diabetic self-care behaviors; etiologic factors: decreased value on life and decreased motivation to learn.
A single sign or symptom	After successfully administering own insulin for 3 days, patient tells nurse, “You give me my shot today.”	A problem statement is not developed until a pattern or cluster of significant cues is detected. The signs and symptoms lead to the identification of the problem statement but are not the problem statement. In this situation, no problem statement is indicated until further data collection, interpretation, and analysis take place.
An *invalidated* nursing inference	Above incident leads to the nursing inference: Nonadherence related to depression	This is a premature problem statement that may not accurately reflect a patient problem. More data and the validation of the tentative problem (nursing inference) are needed before the problem statement can be recorded.

In addition, patients who are able to participate in decision making should be encouraged to validate the problem. “It seems to me that bathing has become a problem now that you are afraid of falling in the tub. What’s your sense of this?” Refer to Table 16-2 on page 438 for a list of possible outcomes of validating tentative nursing diagnoses.

Next Steps

In Chapter 17, you will learn how to plan nursing care to address the patient health problems and issues you have identified. One of your first tasks will be to prioritize your diagnostic statements, and Chapter 17 will teach you how to allow patient preference, Maslow’s hierarchy of human needs, and your anticipation of future problems to guide your clinical reasoning about nursing priorities. You will also be able to use your knowledge of concept mapping (Chapters 13 and 14) to diagram the relationships between your diagnoses/problems and evidence-based interventions.

DOCUMENTING NURSING DIAGNOSES AND PATIENT PROBLEMS

The nurse documents validated nursing diagnoses and actual and potential patient problems in the patient record. Depending on the documentation system in use, nursing diagnoses and problems might be recorded in the nursing care plan and on the multidisciplinary problem list at the front of the patient record. Table 16-3 on page 440 illustrates how to document nursing diagnoses/patient problems using both two- and three-part diagnostic statements.

At one time, nurses were urged to only use NANDA-I accepted terms to state nursing diagnoses. Today, accepted terms vary. Nurses should use the terms recommended by their school, employer, or specialty organization (e.g., Association of periOperative Nurses [AORN] or Association of Rehabilitation Nurses [ARN]). The terms most commonly used will be the terms chosen for standard plans and computerized systems.

Importance of Patient Problems in Electronic Health Records

The goal of the EHR is to enable the interdisciplinary team caring for the patient to more easily view the patient’s risks, health promotion possibilities, and actual current and long-term care problems. Documenting patient problems in the EHR is important for the patient and others providing care. You should use the EHR to:

- view the patient’s ongoing risks (e.g., Risk for Dysfunctional Grief, Risk for Falls) and problems (e.g., Impaired Gastrointestinal System Function: Constipation, Burn Wound) that others have identified and documented.
- decide on and document new patient problems based on the patient assessment findings.
- facilitate communication of the patient’s actual problems with nurses and others on the care team.
- use the list of patient problems to make decisions about what mutual goals the patient desires (patient outcomes) and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

what can be done (nursing interventions).
- determine and document when the patient problems are resolved.

NURSING DIAGNOSIS: A CRITIQUE

Current nursing diagnosis literature contains many examples of nurses writing about how using nursing diagnoses has improved their clinical practice; articles also detail the many benefits nursing diagnosis brings to the profession. Conversely, other articles point out the limitations of nursing diagnosis and urge nurses to be cautious so that an uncritical use of nursing diagnosis does not restrict their practices.

The primary benefit of nursing diagnosis for the patient is the individualization of patient care—this is true whether nurses are identifying what are called nursing diagnoses or actual or potential problems. For example, nurses might be caring simultaneously for three women who have had a modified radical mastectomy because of breast cancer. Although the postoperative nursing management of these women is similar, priorities of care may differ. A prioritized list of nursing diagnoses/problems enables nurses to direct their energies toward these differing patient priorities. Here are some examples of nursing diagnoses/problems for three different women with modified radical mastectomy:

Patient A

- Disturbed Body Image
- Coping impairment

Patient B

- Acute Pain
- Bathing/hygiene ADL deficit

Patient C

- Impaired Sexual Functioning
- Risk for Powerlessness

The use of nursing diagnoses/problems also allows patients to be informed and willing participants in their care, as they validate their diagnoses/problems and assist in prioritizing them. The process of prioritizing nursing diagnoses/patient problems is the first step in planning care, addressed in Chapter 17.

Improved communication between nurses and other health care professionals is probably the most important benefit of accurate, up-to-date diagnostic statements—expressed in well-defined and standardized terminology—for nurses. This communication aids in planning, charting, patient data retrieval, health team conferences, change-of-shift reports, and health care follow-up. It also promotes nursing accountability for the problems that nurses diagnose.

If the diagnostic process is used incorrectly, however, a patient might be "misdiagnosed." Common sources of error include the following:

- *Premature diagnoses based on an incomplete database:* For example, a diagnosis of Coping impairment is made after the patient verbally attacks one nurse who was attempting to teach him self-care for his wound.
- *Erroneous diagnoses resulting from an inaccurate database or a faulty data analysis:* For example, a diagnosis of Dysfunctional Grief is made in a patient observed crying after learning that her cancer had returned, before anyone had time to evaluate whether this was simply an appropriate response to bad news.
- *Routine diagnoses resulting from the nurse's failure to tailor data collection and analysis to the unique needs of the patient:* For example, a diagnosis of Knowledge deficiency is made in a patient with diabetes who is frequently hospitalized with diabetes-related complications, when she actually has excellent knowledge of diabetes and related self-care demands but has lacked the motivation to care for herself appropriately.
- *Errors of omission:* Failure to modify diagnoses and to identify new diagnoses as the patient's status changes may also be problematic. Failures in diagnosis lead to failures in nursing care.

Recall **Martin Prescott**, the 46-year-old man with rectal bleeding and constipation. Although an initial nursing problem statement may involve Knowledge deficiency of possible causes of rectal bleeding, further assessment may reveal that the patient's constipation resulting from a diet inadequate in fiber and fluids is the underlying cause of the bleeding. Thus, the nurse would need to revise the problem statement to focus

on Constipation; etiology: inadequate intake of high-fiber foods and fluids; signs/symptoms: hard stool and rectal bleeding.

The above examples of misdiagnosis don't show the limitations of nursing diagnosis; rather, they are problems of nurses diagnosing incorrectly. More serious criticisms of nursing diagnoses are raised by nurses who claim that a classification of standardized diagnoses limits nursing, curbing nurses' originality and ability to think things through.

Although some nurses believe that diagnosis offers a valued shortcut to practice, critics find this attitude offensive, and respond that rather than invest nursing's energies in perfecting a shortcut, nurses need to change working conditions that interfere with in-depth problem solving and thoughtful nursing care.

Early critics of diagnostic labeling point out that instead of identifying what is unique and positive about nursing, nursing diagnoses make a clear statement that nurses are concerned about what is deviant, wrong, or pathologic (Hagey & McDonough, 1984). These critics claim that the ever-changing and dynamic human person with a need for nursing care becomes objectified. The practice of many experienced nurses who find nursing diagnoses helpful in targeting care for patients with diverse needs counters these concerns.

Nurses who are sensitive to transcultural issues raise important concerns about the cultural limitations of some diagnoses. Foremost among these concerns is that some diagnoses and behaviors assume that the patient is "wrong," and the provider is "right" and deny the validity of cultural and health care beliefs and practices that are different from those of the nurse (Geissler, 1991). Examples of nursing diagnoses that often are misused in labeling such cultural deviations as abnormal include Impaired Verbal Communication, Impaired Socialisation, and Nonadherence. Nurses who provide culturally sensitive care (see Chapter 5) and who work collaboratively with the patient as a partner avoid these problems.

In conclusion, diagnosis/analyzing has become a valued and essential phase in the nursing process. Used correctly, it is a powerful tool for individualizing patient care and ensures that nurses' energies are being used in the most efficient way to meet prioritized and holistic patients' needs. Nurses who are as concerned about the art and spirit of nursing as they are about its science are careful to avoid labeling patients in a way that objectifies them or limits the potential range of nurse–patient interactions.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in diagnosing health problems and identifying patient strengths, reflect on your experiences—both successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Alfaro-LeFevre (2014) recommends paying close attention to the following during the diagnosing phase of the nursing process:

- Has patient and family participation in the process been at an optimal level? How might you have better engaged the patient and family?
- Are your data reliable, accurate, and complete? How do you know this?
- Have you identified the assumptions you made about patient cues?
- Are your conclusions based on facts (evidence) rather than guesswork?
- Have you considered alternate conclusions, ideas, and solutions?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of diagnosing their health problems and identifying and tapping their strengths? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Find a patient with a well-established medical condition. List potential medical diagnoses and actual and potential diagnoses, problems, and issues that a nurse can treat. Explain the differing purposes of medical diagnoses and the diagnoses, problems, and issues that nurses and the collaborative team can treat. What is nursing's diagnostic contribution to the interdisciplinary team's effort to care for this patient?
. Try to assess a patient with another student and independently identify their strengths. Compare the lists you generated. What explains your differences?
. Interview two patients with the same medical diagnosis. Develop a prioritized list of diagnoses/problems/issues for both, and reflect on the differences. Compare and contrast the strengths of both patients. If you can do this exercise with another student, it would be helpful to explore why there are differences in your lists of nursing diagnoses and patient strengths.
. Reflective nurses realize that they bring their personal attributes, knowledge, and competencies to the process of diagnosing. What personal strengths and limitations do you expect to influence your ability to diagnose health problems and identify and tap strengths?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

PRACTICING FOR NCLEX

. A registered nurse is formulating nursing diagnoses for a patient with multiple fractures. Which actions does the nurse take during this step of the nursing process? Select all that apply.

a. Conducting a nursing interview to collect patient data
b. Analyzing data collected in the nursing assessment
c. Developing a care plan for the patient
d. Pointing out the patient's strengths
e. Assessing the patient's mental status
f. Identifying community resources to help the family cope

. A nurse is caring for a patient who presents with dyspnea, tachypnea, productive cough, fever, and low oxygen saturation. When developing the nursing care plan, which health problems might the nurse identify for this patient? Select all that apply.

a. Bronchial pneumonia
b. Impaired gas exchange
c. Impaired Respiratory System Function
d. Altered breathing pattern
e. Impaired Thermoregulation

. After assessing a patient recovering from a stroke in a rehabilitation facility, the nurse's initial analysis suggests a potential health problem of situational low self-esteem. How will the nurse record the problem when they believe more data are needed?

a. No problem
b. Possible problem
c. Actual nursing diagnosis
d. Clinical problem other than nursing

. When caring for a patient who sustained a spinal cord injury, the nurse formulates the health problem:
Impaired Tissue Integrity
Etiology: sensory and motor deficit
Signs and symptoms: difficulty turning, reddened areas on heels and sacrum
Which phrase gives direction to the underlying cause of the problem?

a. Impaired Tissue Integrity
b. Sensory and motor deficit
c. Signs and symptoms
d. Reddened areas of skin on the heels and back

. A nurse is caring for a patient who refuses to look at or care for a new colostomy. The patient states, "I don't care what I look like anymore. I'm not washing up, let alone touching or changing this bag!" The nurse formulates the health problem: Difficulty Coping: Impaired Acceptance of Health Status, reflecting which type of health problem?

a. Collaborative
b. Interdisciplinary
c. Medical
d. Nursing

. A nursing student obtains a blood pressure reading of 148/100. To determine the significance of this reading, what action will the nurse take first?

a. Comparing this reading to standards and trends in the medical record
b. Checking the taxonomy of nursing diagnoses for a pertinent label
c. Checking a medical text for the signs and symptoms of high blood pressure
d. Consulting with experienced nurse colleagues

. A nursing student tells the primary nurse that their patient has not had a bowel movement for 2 days and suggests adding the health problem "Constipation" to the care plan. How would the nurse best respond?

a. "Did you assess the patient's usual bowel patterns and appearance of the last stool?"
b. "This early diagnosis will help us manage the problem before it becomes severe."
c. "Have you determined if this is an actual or a possible diagnosis?"
d. "This condition requires a medical diagnosis."

. A nurse is caring for a patient who has been admitted the second time this month for hypertensive emergency. The

care plan contains the health problem:
Nonadherence
Etiology: lack of knowledge of purpose of medications
Signs and symptoms: BP, 220/112; readmitted for hypertensive crisis after 2 weeks
When meeting the patient, which action will the nurse take first?

a. Teach the patient that nonadherence may lead to stroke and heart disease
b. Discuss what will motivate the patient to adhere to the medication regimen
c. Explain that these medications are essential to their health and illness prevention
d. Determine the patient's knowledge about the medications and their side effects

. A nurse in the psychiatric clinic is developing a problem list for a patient. What statement best reflects a correctly written, two-part problem?

a. Difficulty Coping: Impaired Family Coping
   Etiology: inability to maintain marriage
b. Difficulty Coping: Impaired Acceptance of Health Status
   Etiology: anger management issues
c. Impaired Cognition: Distorted Thought Process
   Etiology: psychosis as evidence by hallucinations
d. Impaired Cognition: Decisional Conflict
   Etiology: placement of parent in a long-term care facility

. A nurse is developing a problem list for a care plan. Which reflects a correctly written three-part problem statement? Select all that apply.

a. Difficulty Coping: Impaired Family Coping:
   Etiology: lack of knowledge about tube feeding
   Signs and symptoms: child needing tube feeding discharged to home
b. Impaired Nutritional Status: Impaired Nutritional Intake
   Etiology: striving for perfect weight, wishes to excel in gymnastics
   Signs and symptoms: 20-lb weight loss in 1 month
c. Need to learn how to care for child on ventilator at home
   Etiology: discharge of child after 3-month hospital stay
   Signs and symptoms: repeated comments, "I know I'll harm her because I'm not a nurse." and "I can't do medical things."
d. Impaired Spiritual Status
   Etiology: inability to accept diagnosis of terminal illness
   Signs and symptoms: comments such as, "I don't deserve this"; "I've tried to live my life well"; and "How could God make me suffer this way?"
e. Impaired Tissue Integrity: Impaired Skin Integrity
   Etiology: failure of home health aides to turn patient every 2 hours
   Signs and symptoms: stage 3 pressure wound on sacrum.

. A nurse is caring for a patient recovering from a stroke that paralyzed the dominant arm. The nursing assistant reports that the patient was unable to bathe, comb their hair, or brush their teeth. Which health problem should the nurse add to the care plan?

a. Lack of motivation to complete self-care activities
b. Risk for: Activities of Daily Living Deficit
c. ADL deficit: impaired dressing and grooming
d. Impaired musculoskeletal system function: paralysis

. A nurse is caring for a patient who had abdominal surgery yesterday. The nurse observes the patient guarding the area with hands and a pillow, refusing to move, and grimacing. What information does the nurse use to formulate the health problem statement?

a. Symptoms
b. Diagnostic statement
c. Etiology
d. Cue

. When developing the admission care plan for a patient with multiple sclerosis and quadriplegia, the nurse formulates the patient problem: Impaired Tissue Integrity: Impaired Skin Integrity. What action will the nurse take next?

a. Elevate the patient's heels off the bed using a pillow
b. Develop a goal that the patient will consume protein at each meal

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

c. Delegate assessment of the skin on the patient's back to the AP
d. Teach the patient to turn themselves in bed every hour

. A nurse has performed an admission assessment on a patient. What step does the nurse perform after clustering the data?
a. Developing interventions
b. Nursing judgments
c. Diagnosing and analyzing
d. Concept mapping

. A nurse notices a patient crying after meeting with the health care provider. Prior to formulating a health problem of difficulty coping, the nurse seeks to further support the problem by gathering which data?
a. Abnormal vital signs
b. Underlying cause of the tears
c. Admitting diagnosis
d. Patient's support system

ANSWERS WITH RATIONALES

. **b, d, f.** Diagnosing includes identifying actual or potential health problems for individuals, groups, or communities; identifying factors that contribute to or cause health problems (etiologies); and identifying resources or strengths the individual, group, or community can draw on to prevent or resolve problems. The nurse assesses and collects patient data in the assessment step and develops the care plan during the planning phase of the nursing process.

. **b, c, d, e.** Nursing diagnoses are actual or potential health problems that can be prevented or resolved by independent or interdependent nursing interventions. These include Impaired gas exchange, supported by low oxygen saturation; Impaired Respiratory System Function; Altered breathing pattern, supported by dyspnea and tachypnea; and Impaired Thermoregulation. Pneumonia is a medical diagnosis.

. **b.** When a possible problem exists, the nurse must collect more data to confirm or disprove the suspected problem. The conclusion, "no problem," indicates no nursing response is required. When an actual problem is identified, the nurse continues using the steps of the nursing process by planning, goal setting, implementing, and evaluating care to resolve the problem. A clinical problem other than nursing diagnosis requires a collaborative approach with the appropriate health care professionals.

. **b.** The etiology, sensory and motor deficits, identifies the contributing or causative factors of the problem. The problem, "Impaired Tissue Integrity: Impaired Skin Integrity," states the undesirable health condition, life processes, or human response. The phrase, "Signs and symptoms: non-blanchable reddened areas on heels and back," contains the defining characteristics of the problem.

. **d.** Difficulty Coping: Impaired Acceptance of Health Status is a nursing problem, falling within the scope of independent nursing practice. Collaborative and interdisciplinary problems are resolved through a teamwork approach with other health care professionals. A medical problem is a traumatic or disease condition validated by medical diagnostic studies.

. **a.** A standard, or a norm, is a generally accepted rule, measure, pattern, or model to which data can be compared within the same class or category. When interpreting the significance of a patient's blood pressure reading, the nurse uses normative values for the patient's age group, race, and illness category and compares these to the patient's recent results. Identifying the reason for deviation from a norm gives direction to the etiology of a health problem (e.g., insufficient knowledge, nutrition, stress, and coping, or other).

. **a.** Patient health problems are derived from clusters of related data and patterns, rather than a single cue. The nurse determines if this is the patient's usual bowel pattern, or whether an underlying reason exists for the lack of a bowel movement. Constipation is a health problem the nurse can resolve with independent or interdependent nursing actions.

. **d.** Using the nursing process, the nurse first assesses the patient's knowledge base; this also confirms the accuracy of the problem statement. Problem statements with unclear etiologies may lead to inappropriate, erroneous, or unhelpful interventions. If the patient has difficulty affording medications or is experiencing side effects, a collaborative problem can be resolved jointly by the nurse, social worker, and health care provider.

. **d.** A correctly written two-part problem statement includes the health problem and the etiology or cause. The problem statement and etiology should avoid signs and symptoms, medical diagnoses, and something that cannot be changed. Inability to maintain marriage and anger issues do not identify the underlying cause of the problem and may themselves reflect the true problem. Psychosis is a medical diagnosis, which should not be used to support a patient problem.

. **d.** Correctly written problem statements contain a problem the nurse can treat with independent or interdependent interventions, a clearly stated etiology or cause of the problem, and supporting signs and symptoms. Option (a) may be more easily resolved with the problem statement, knowledge deficiency. Option (a) further states the tube feeding is

the underlying cause of the problem; it is a factor that cannot be changed. Option (c) is written in terms of needs and not an unhealthy response. Option (e), while written in three parts, places blame or implies negligence, which is legally inadvisable and should be avoided. A clear etiology is not stated in option (e), impeding direction for appropriate interventions or outcomes.

. **c.** The nurse clusters the data that demonstrates the patient's (actual) inability to perform bathing and grooming. For that reason, a "potential problem" or "risk" is not appropriate. There is no evidence the patient lacks motivation, and paralysis is not a problem the nurse can resolve.

. **d.** A cue denotes significant data or "red flags," that, when occurring in a pattern or cluster, point to the existence of a health problem.

. **b.** After the health problem is developed, the nurse begins the planning phase of the nursing process, which includes goal development. Elevating the heels and teaching the patient to turn are interventions used during the implementation phase. Delegating an assessment to the AP is an incorrect activity; assessment falls within the role and scope of practice of the professional nurse. In addition, the nurse must perform the skin assessment to develop the problem and plan care.

. **c.** After clustering the data, the nurse analyzes the data and formulates a nursing diagnosis. Interventions are based on and developed after goal setting. Nursing judgments are outcomes based on critical thinking and clinical reasoning. A concept map is a diagram or pictorial representation of the (student) nurse's understanding of the interactions and relationships of the patient's problems and plan of care.

. **b.** The nurse continues gathering data, determining the presence of a problem of grief, impaired coping, etc., by determining the underlying cause of the tears. If the patient received news that a biopsy was free from cancer, perhaps no problem exists. If the patient was told they have a terminal illness, the nurse can continue to gather data and plan to support the patient's physical and emotional needs.

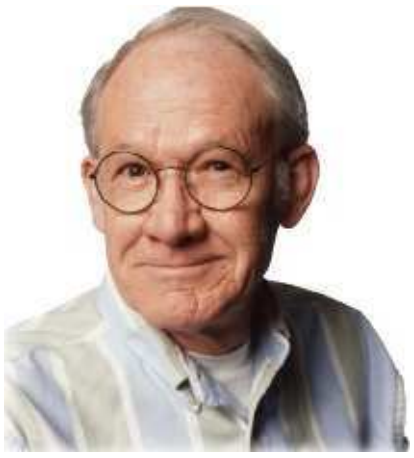
Outcome Identification and Planning

Glenda Kronk

Glenda, a 35-year-old woman, comes to the health center for a routine checkup. During the visit, she expresses a strong motivation and desire to become physically fit, lose weight, increase her muscle tone, and improve her cardiorespiratory capacity. “I know it will involve some major lifestyle changes, including diet. What’s with all these diets and diet supplements now?” she asks.



Darla Jefferson

Darla, a 29-year-old single woman, is about 14 weeks pregnant. She describes herself as a “hopeless addict” who has tried to stop “more times than I can remember.” Although currently drug-free, she is not hopeful of preventing relapse. She does not know the baby’s father and has mixed feelings about keeping the baby, saying, “On the one hand I want someone to love me, but I’m not sure I’d want me for a mother.”

Elijah Wolinski

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Elijah is a thin, frail, 85-year-old man who is bedbound due to severe degenerative joint disease. He is being cared for by his 56-year-old nephew at his home. Assessment on a home visit reveals Elijah lying on soiled linens with a large pressure injury on his sacrum, approximately 5 cm in diameter and about 2 cm deep with purulent drainage.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe the purpose and benefits of outcome identification and planning.
. Identify three elements of comprehensive planning.
. Prioritize patient health problems and nursing responses.
. Describe how patient goals/expected outcomes and nursing orders are derived from diagnoses/patient problems.
. Develop a nursing care plan with properly constructed outcomes and related nursing interventions.
. Differentiate nurse-initiated interventions, physician-initiated interventions, and collaborative interventions.
. Use criteria to evaluate planning skills.
. Describe five common problems related to planning, their possible causes, and remedies.
. Describe the rationale for standardized outcomes (NOC) and interventions (NIC) for nursing.

planning
standardized care plans

After the nurse collects and interprets patient data, identifying patient strengths and health problems, it is time to plan for nursing actions (see the accompanying Reflective Practice box for an example). During the **outcome identification** and **planning** phase of the nursing process (Fig. 17-1 on page 452), the nurse works in partnership with the patient and family to:

- Establish priorities
- Identify and write expected patient outcomes
- Select evidence-based nursing interventions
- Communicate the nursing plan of care

A **goal** is an aim or an end. A **patient outcome** is an expected conclusion to a patient health problem, or in the event of a wellness diagnosis, an expected conclusion to a patient's health expectation. The words *goal, objective,* and *outcome* are often used interchangeably. In some practice settings, the term *goal* or *objective* is used to describe what is wanted, and the term *outcome* is used to describe the results achieved. In nursing, the phrase **expected outcomes** is used to refer to the more specific, measurable **criteria** used to evaluate the extent to which a goal has been met. This chapter uses *outcome* to refer to expected patient outcomes.

The nurse, patient, and family should work together as much as possible in the outcome identification and planning stage. If the outcomes specified in the care plan are not valued by the patient or do not contribute to the prevention, resolution, or reduction of the patient's problems or the achievement of the patient's health expectations, the care plan may be ineffective. Similarly, if social determinants of health create barriers that prevent the patient from realizing the outcomes, these need to be explored. Outcome determination is, therefore, a critical skill for successfully intervening with patients.

This chapter describes outcome identification and planning as a formal process, a deliberate phase in the nursing process. A formal plan of care allows nurses to:

- Individualize care that maximizes outcome achievement
- Set priorities
- Facilitate communication among nursing personnel and their colleagues
- Promote continuity of high-quality, cost-effective care
- Coordinate care
- Evaluate the patient's responses to nursing care
- Create a record that can be used for evaluation, research, reimbursement, and legal purposes
- Promote the nurse's professional development

Nurses also engage in informal planning in practice. This is the link between identifying a patient's strength or problem and providing an appropriate nursing response.

A nurse on a busy surgical unit learns that a postoperative patient is complaining of incisional pain; they quickly reshuffles priorities to allow time to assess the course and qualities of the pain, and to determine nursing measures to reduce discomfort. Planning has occurred. A postpartum nurse realizes the evening before the mother's discharge that they has not seen the father hold his new daughter; they make a mental note to observe the father–daughter interactions that evening and facilitate their bonding. Planning has occurred. A nurse in a geriatric daycare center hears a patient choking and rushes to their side to perform the Heimlich maneuver if necessary. Planning has occurred.

Informal planning on a more deliberate level is illustrated by a hospice nurse who drives home pondering how best to support a patient with terminal cancer who is gradually relinquishing her hold on life. The hospice nurse may elect to initiate a more formal process of planning the next day when consulting with colleagues who have cared for patients with similar health needs.

In each of these examples, the process of informal planning allowed an individual nurse to think about how best to help a particular patient—ideally, with good results. What is lacking is a coordinated plan known by everyone caring for the patient.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

While working in a women's shelter, I met Darla Jefferson, a 29-year-old single woman who was about 14 weeks pregnant. Darla described herself as a "hopeless addict" who had tried to stop "more times than I

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

can remember." She was drug-free at the moment but not hopeful of preventing relapse. She did not know her baby's father and had mixed feelings about keeping the baby. She said, "On the one hand I want someone to love me, but I'm not sure I'd want me for a mother." I knew I needed to explore her commitment to this pregnancy, but I am strongly opposed to abortion and did not think I could talk with her objectively about her decision. I needed to develop a plan for dealing with this issue.

Thinking Outside the Box: Possible Courses of Action

- Tell Darla that I believe it is her responsibility to have this baby and to then make a decision about whether to offer the baby for adoption based on her assessment of her parenting readiness.
- Help Darla assess her readiness to become a parent and, in light of this, explore all her options regarding continuing or terminating the pregnancy.
- Get someone else to talk with Darla so that she gets the counseling she needs and I am not morally compromised.

Evaluating a Good Outcome: How Do I Define Success?

- Darla gets the help she needs to make the decision that is right for her and her unborn baby.
- I am faithful to both my nursing responsibilities to counsel this patient and my duty to maintain my moral integrity.

Personal Learning: Here's to the Future!

Unfortunately, I overestimated my ability to counsel Darla without compromising myself, and as a result, I don't think I was as helpful to her as I should have been. Ideally, I planned to objectively explore her readiness to be a mother and then have an open and unbiased discussion about her options. When she began to talk about getting an abortion, I found myself urging her to have the baby and then place the baby up for adoption if she still felt she couldn't care for the infant after delivery. Regrettably, I let my personal opinions come through in the discussion. Through my actions, I think she lost trust in me. I'm going to talk with other nurses to see how they handle this challenge.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How would you respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your competencies for professional practice? Can you think of other ways to respond? What actions might have proved more effective? What actions might be helpful for the nursing student so that when faced with similar situations in the future, the outcome would be more positive? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Jefferson?

Patient-Centered Care: How would you develop a successful partnership with Ms. Jefferson, knowing that she may choose an alternative that is unethical for you? Are nurses obligated to be ethically neutral when issues like this come up? How can you best communicate empathy and that you respect her even when you disagree with choices she makes?

Teamwork and Collaboration/Quality Improvement: What communication and interpersonal skills do you need to improve to ensure that you function as a member of the patient care team and to obtain assistance when needed? What does quality care for Ms. Jefferson look like?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Ms. Jefferson? What safety needs do she and her unborn baby have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Ms. Jefferson's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

UNIQUE FOCUS OF NURSING OUTCOME IDENTIFICATION AND PLANNING

The primary purpose of the outcome identification and planning step of the nursing process is to design a plan of care with and for the patient that, once implemented, results in the prevention, reduction, or resolution of patient health problems and the attainment of the patient's health expectations, as identified in the patient outcomes.

Become familiar with the registered nurse competencies for Standards 3 (Outcomes Identification) and 4 (Planning)

in ANA's *Nursing: Scope and Standards of Practice* (2021). A comprehensive care plan additionally specifies any routine nursing assistance the patient needs to meet basic human needs (e.g., assistance with hygiene or nutrition) and describes appropriate nursing responsibilities for fulfilling the collaborative and medical care plan. For example, health care providers may delegate to nurses caring for a surgical patient the redressing of the surgical incision, the administration of prescribed medications and intravenous therapy, and the responsibility for scheduling laboratory studies. Nurses design care plans that incorporate their independent, dependent, and collaborative responsibilities. See the clinical decision making process illustrated in Figure 17-2 to help determine when you can act independently within your scope of practice. Because nursing is concerned with the patient's responses to health and illness, the plan of care is supportive of nursing's broad aims: to promote wellness, prevent disease and illness, promote recovery, and facilitate coping with altered functioning (see Chapter 1).

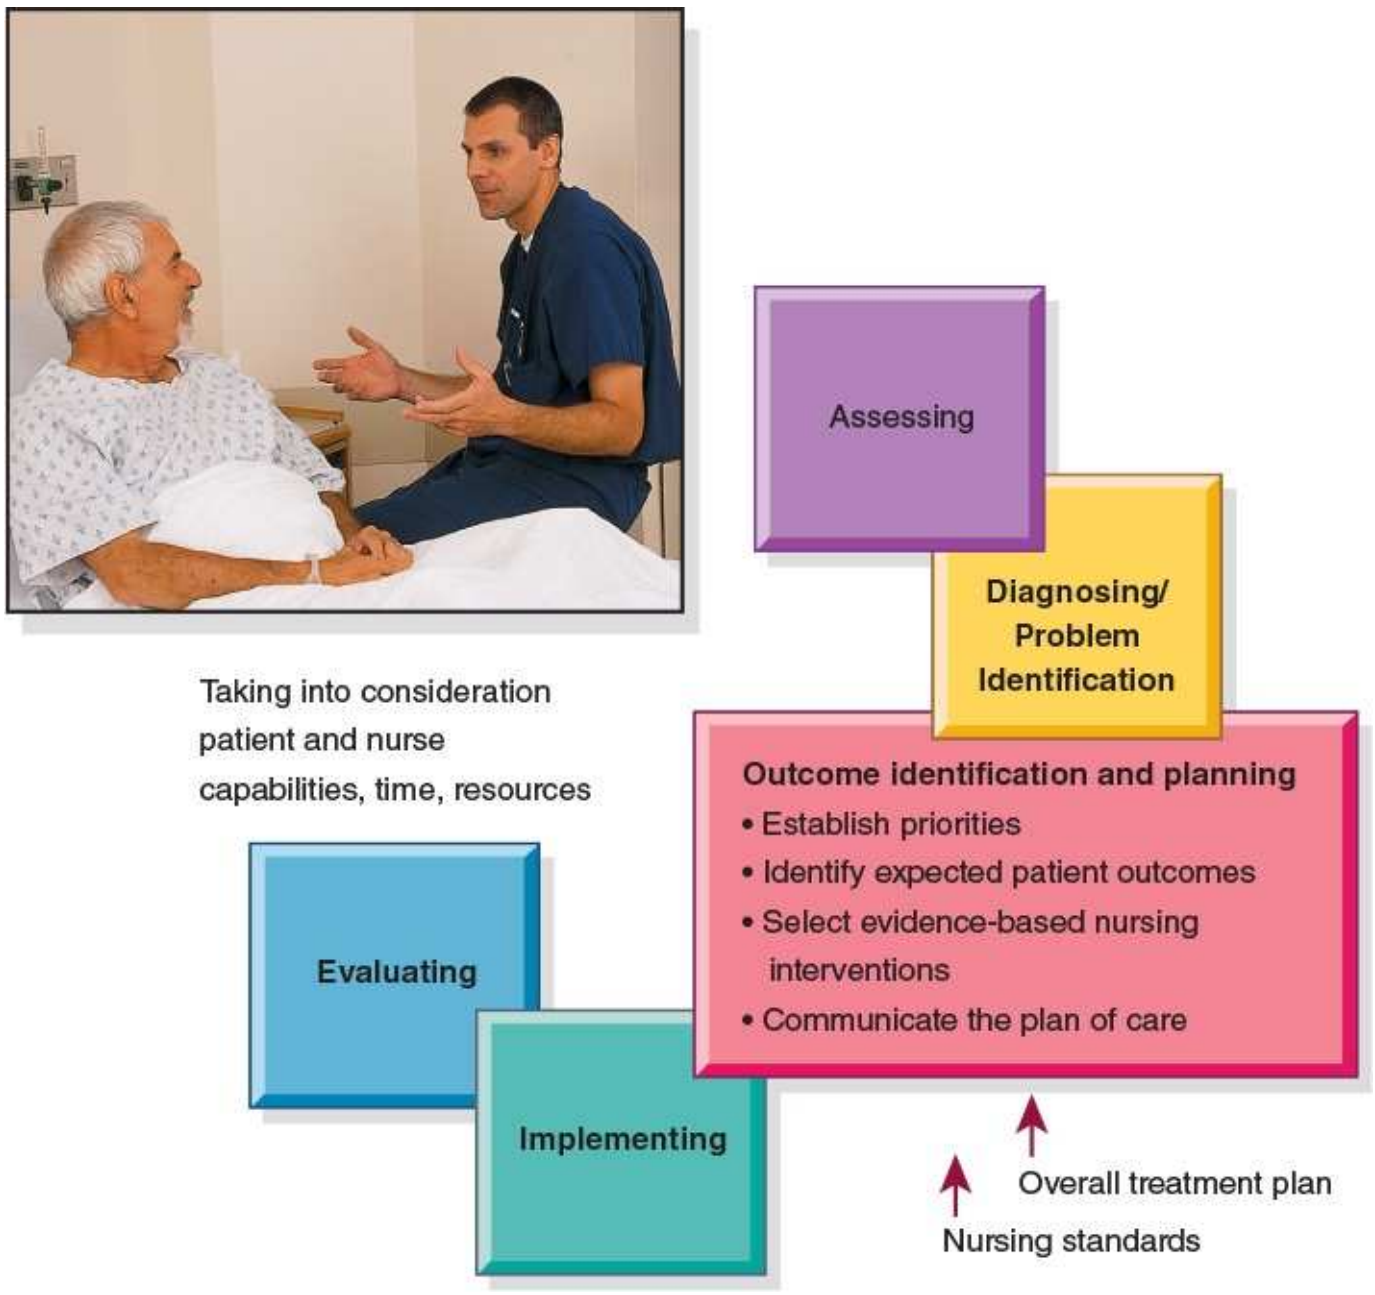

FIGURE 17-1. Outcome identification and planning. The nurse and patient work together to establish priorities, identify expected patient outcomes, and select evidence-based nursing interventions. The care plan should be consistent with nursing standards, congruent with other planned therapies, and realistic in terms of the patient's and nurse's abilities or resources. Ensuring that the care plan is recorded is also an important nursing responsibility. (Used with permission from Shutterstock. *Photo by B. Proud*.)

Critical Thinking/Clinical Reasoning and Judgment in Outcome Identification and Planning

Successful implementation of each phase of the nursing process requires high-level skills in critical thinking and specifically in clinical reasoning and judgment. To plan health care correctly, in your role as nurse, you must:

- Be familiar with standards and facility policies for setting priorities, identifying and recording expected patient outcomes, selecting evidence-based nursing interventions, and recording the care plan (Box 17-1).
- Remember that the goal of thoughtful, person-centered practice is to keep the patient and the patient's interests and preferences central in every aspect of planning and outcome identification.
- Keep the "big picture" in focus: What are the discharge goals for this patient, and how should this direct each nurse's interventions?
- Trust clinical experience and judgment but be willing to ask for help when the situation demands more than your qualifications and experience can provide; value collaborative practice.
- Respect your clinical intuitions, but before establishing priorities, identifying outcomes, and selecting nursing interventions, be sure that research supports your plan.
- Recognize your personal biases and keep an open mind.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Remember **Darla Jefferson**, the pregnant woman with a history of drug abuse described in the Reflective Practice box on page 451. Although the nursing student planned to engage the patient in an unbiased discussion of her alternatives, the student was unable to adhere to the plan, inserting personal opinions in the discussion. As a result, the care plan was thwarted and the patient lost trust in the student.

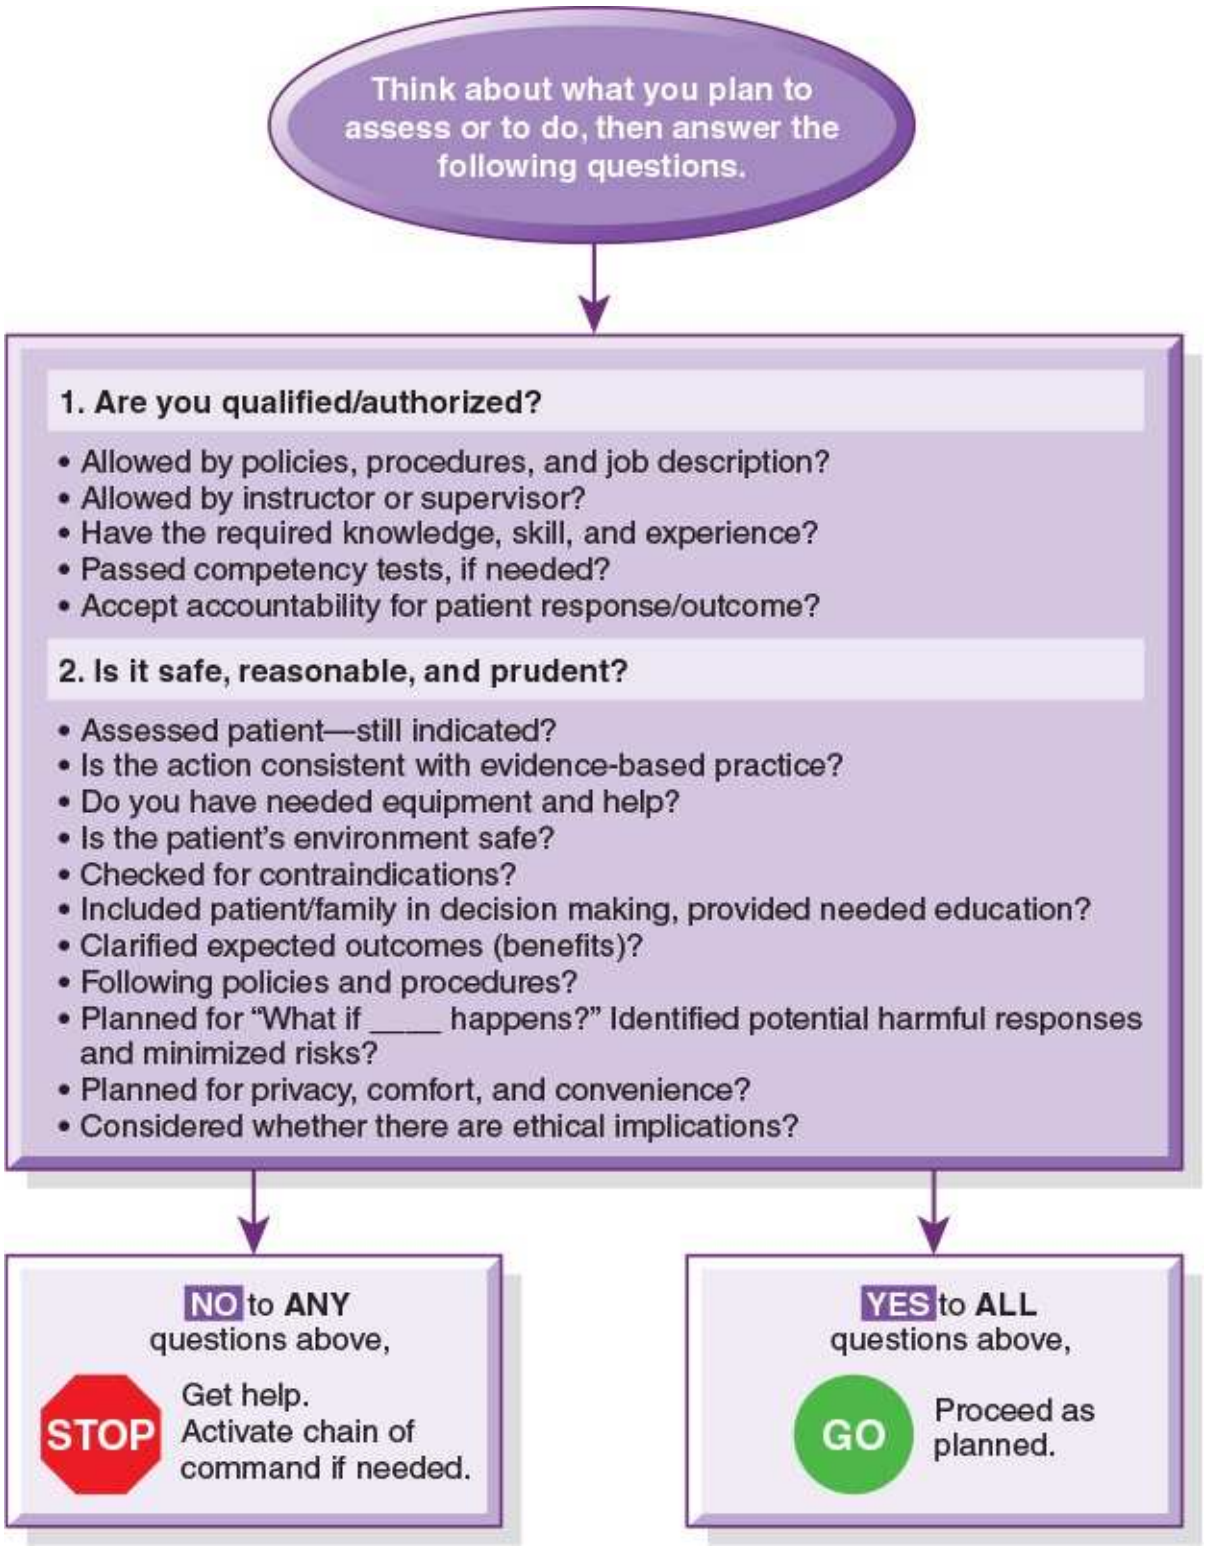

FIGURE 17-2. **C**linical decision making and scope of practice. (*Source*: © 2019 R. Alfaro-LeFevre. http://www.AlfaroTeachSmart.com.)

Questions to facilitate clinical reasoning and judgment during planning and outcome identification include:

- *Setting priorities:* Which problems require my immediate attention or that of the team? Which problems are my responsibilities, and which should I refer to someone else? Which problems are most important to the patient?
- *Identifying outcomes:* What must I observe in the patient to demonstrate the resolution of the problems identified by the nursing diagnoses and general problem list? What is the time frame for accomplishing these outcomes? Do the outcomes need to be modified in light of the patient's response (or lack of response) to the planned interventions?

Box 17-1 **Applying Standards to Plan Nursing Care**

The standards you must apply when identifying outcomes and related nursing interventions are determined by:

- *The law.* Your state's nurse practice act outlines the scope of nursing practice. Your State Board of Nursing also outlines what you are and are not allowed to do.
- *Specialty professional organizations,* such as the American Association of Critical Care Nurses or Emergency Nurses Association, which develop standards for specialty practice.
- *The Joint Commission.* This powerful accrediting body has developed detailed standards that must be followed to keep accreditation.
- *The Agency for Healthcare Research and Quality (AHRQ).* This organization develops, reviews, and updates clinical guidelines to aid health care providers to prevent, diagnose, and manage clinical conditions.
- *Your employer.* Each facility usually develops its own unique set of standards (standards of care, guidelines, policies, procedures, critical pathways, standard care plans, and so forth) that reflect how nursing care should be given in specific situations.

Source: Reprinted with permission from Alfaro-LeFevre, R. (2010). Applying nursing process: A tool for critical thinking (7th ed., pp. 144–145). Wolters Kluwer Health/Lippincott Williams & Wilkins.

- *Selecting evidence-based nursing interventions:* What do nursing science and my clinical experience suggest is the likelihood that this particular nursing intervention will help the patient realize their expected outcomes? How can I tailor my interventions to increase the likelihood of patient benefit? What is the worst thing that might happen with this intervention, how likely is it to happen, and what can I do to minimize the possibility of this harm?
- *Communicating the care plan:* Does the care plan adequately address the patient's priorities today? If the care plan is computerized or standardized, does it adequately address the specific needs of this particular patient? Will anyone reading the care plan know how to intervene effectively with this patient?

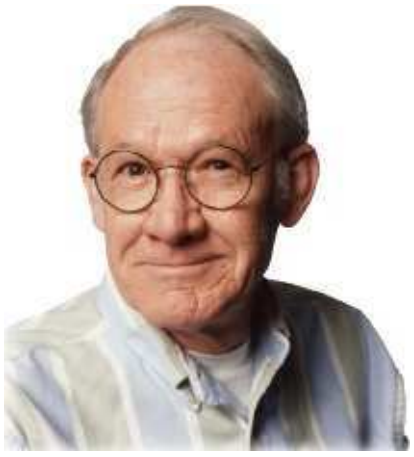
Interpersonal Competence in Outcome Identification and Planning: Working With Patients and Families

As in every phase of the nursing process, your interpersonal competence influences your success in planning. As a nurse, you are uniquely positioned to understand patient and family needs, expectations, hopes, and fears; this is what allows you to develop effective care plans. Unless patients believe that you are committed to meeting their health and well-being needs, they have little incentive for partnering with you. The more active that patients and families are in the planning process, the more motivated they will be to achieve valued goals. While standardized care plans predominate in care settings today, your challenge is to individualize such plans to the unique needs of your patients. Your patients will quickly form judgments about how interested you are in learning enough about them to help them realistically set and meet valued outcomes.

COMPREHENSIVE PLANNING

In acute care settings, three basic stages of planning are critical to comprehensive nursing care: initial, ongoing, and discharge. In other settings such as long-term care, hospice care, or a community clinic, initial and ongoing planning may be the primary types of planning. If a nurse develops a comprehensive plan of care on the patient's first day but fails to update the plan, the plan will not be effective or efficient. Failure to update the plan of care as needed is a common problem in all health care settings.

Initial Planning



Initial planning is performed by the nurse with the admission nursing history and the physical assessment. This comprehensive plan addresses each problem listed in the prioritized nursing diagnoses and identifies appropriate patient goals and the related nursing care. **Standardized care plans** are prepared care plans that identify the nursing diagnoses, outcomes, and related nursing interventions common to a specific population or health problem. (An example of a standardized care plan is shown later in the chapter.) They can provide an excellent basis for the initial plan if the nurse individualizes them. Resources for standardized plans include computerized plans, textbooks with prepared care plans, and facility-developed plans/maps/critical pathways. By using such standardized plans, the nurse is free to direct time and expertise to individualizing the plan.

Ongoing Planning

Ongoing planning is carried out by any nurse who interacts with the patient. Its chief purpose is to keep the plan up to date to facilitate the resolution of health problems, manage risk factors, and promote function. The nurse caring for the patient uses new data as they are collected and analyzed to make the plan more specific and accurate and, therefore,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

more effective. The work of ongoing planning includes stating nursing diagnoses/problems more clearly (both the problem statement and the cause), developing new diagnoses/problems, adjusting patient outcomes to be more realistic, developing new outcomes as needed, and identifying nursing interventions that will best accomplish the patient goals.

Consider **Elijah Wolinski**, the frail, older adult who developed a pressure injury. Ongoing planning is necessary because the patient's pressure injury would most likely take some time to heal or improve. In addition, other needs may become apparent during subsequent home visits, requiring the nurse to update the care plan.

At this stage of planning, standardized plans based on medical conditions or procedures may be useful in developing new nursing diagnoses/problems and related nursing interventions, but individualizing the plan is necessary to meet unique patient needs. For example, the standard nursing order "force fluids" might be rewritten as "offer 60-mL cranberry or orange juice between meals, and keep fresh water at bedside." A preliminary order such as "explore with the patient existing supports" might be replaced with "keep daughter Barbara informed of mother's progress and coach her in effective support strategies: Barbara Clems, (h) (703) 448–3211, (w) (202) 654–8999."

Discharge Planning

Discharge planning is best carried out by the nurse who has worked most closely with the patient and family, possibly in conjunction with a nurse or social worker with a broad knowledge of existing community resources. In acute care settings, comprehensive discharge planning begins when the patient is admitted for treatment—or even before admission. Careful planning ensures that the nurse uses teaching and counseling skills effectively to help the patient and family develop sufficient knowledge of the health problem and the therapeutic regimen to carry out necessary self-care behaviors at home competently. Discharge planning is further discussed in Chapter 12.

ESTABLISHING PRIORITIES

To develop a prioritized list of nursing diagnoses/problems, the nurse needs guidelines for ranking diagnoses as high, medium, or low priority. High-priority diagnoses pose the greatest threat to the patient's health and well-being. Diagnoses/problems that are not life threatening are ranked as medium priorities, and diagnoses/problems that are not specifically related to the current level of health or well-being are of low priority. In all levels, psychosocial needs must be considered as well as physiologic needs.

In addition to developing a prioritized list of nursing diagnoses/problems, nurses working within an interdisciplinary team need to set priorities for nursing care that take account of all the patient's health needs, as recorded on the general problem list. This involves looking at all problems to determine the relationships among the problems (what's causing or contributing to what). Thus, it generally makes sense to deal with medical (or suspected medical) problems first. If these can be resolved, many human response problems are gone. If a nurse sees the classic signs and symptoms of appendicitis and tries to identify and manage a nursing diagnosis of pain without consulting a physician or nurse practitioner, the patient's appendix might rupture before a nursing plan to relieve pain is even developed!

Three helpful guides to facilitate clinical reasoning when prioritizing patient problems include Maslow's hierarchy of human needs, patient preference, and anticipation of future problems.

Maslow's Hierarchy of Human Needs

Because basic needs must be met before a person can focus on higher ones, patient needs may be prioritized according to the following hierarchy:

. Physiologic needs
. Safety needs
. Love and belonging needs
. Self-esteem needs
. Self-actualization needs

For example, a geriatric patient who is incontinent of urine and sitting in a wet disposable brief (physiologic need) will be unable to participate fully in a music therapy diversional activity (self-esteem need) until the more basic need is met. (Chapter 4 more fully discusses basic human needs.)

Patient Preference

Thoughtful, person-centered practice directs you to first meet the needs that the patient thinks are most important, as long as this order does not interfere with other vital therapies. For example, a woman is admitted to an orthopedic unit with a fractured pelvis and multiple lacerations after an automobile accident. The morning after the accident, she complains of pain and needs assistance with bathing and attention to her lacerations, but she refuses to do anything until she calls home to find out who is caring for her 15-month-old twins. The nurse should help her to call home before beginning other care as long as it does not interfere with life-saving emergency care.

Anticipation of Patient Needs

Nurses must tap their knowledge base to consider the potential effects of different nursing actions. Assigning low priority to a diagnosis that the patient wants to ignore but can result in harmful future consequences for the patient might be nursing negligence. For example, a patient experiencing obesity patient with multiple sclerosis and greatly decreased limb strength who spends most of their day in bed may see no value in diet modification and position changes. A nurse who is alert to the potentially serious problem of pressure injuries would assign high priority to this diagnosis, nonetheless, and incorporate weight management and position changes into the care plan despite the patient's reluctance.

Critical Thinking/Clinical Reasoning and Judgment and Establishing Priorities

The work of setting priorities demands careful clinical reasoning. Alfaro-LeFevre (2014, p. 132) suggests that nurses ask themselves these four questions:

. What problems need immediate attention and what could happen if I wait to attend to them? Nurses can then initiate actions to solve problems with simple solutions, such as repositioning a patient to improve her breathing or calling a family member in.
. Which problems are my responsibilities and which do I need to refer to someone else?
. Which problems can be dealt with by using standard plans (e.g., critical paths, standards of care)?
. Which problems aren't covered by protocols or standard plans but must be addressed to ensure a safe hospital stay and timely discharge (or simply safe care of high quality)?

Think back to **Darla Jefferson**, the pregnant woman with a history of drug abuse. The nurse would incorporate clinical reasoning by asking these four questions, thereby ultimately arriving at the patient problems requiring the most immediate attention.

When planning nursing care for each day, consider the following:

- Have changes in the patient's health status influenced the priority of nursing diagnoses/problems? For example, when a routine home visit to an older adult reveals evidence of possible elder abuse, a new diagnosis may result in a new set of care priorities.
- Have changes in the way the patient is responding to health and illness or the care plan affected those nursing diagnoses/problems that can be realistically addressed? For example, a nurse might have identified coping as a high-priority problem for the patient after the patient learned the medical diagnosis and planned to initiate counseling. If the patient adamantly requests to be left alone for a day to think things through, however, the nurse has to modify priorities of care for that day.
- Are there relationships among diagnoses/problems that require that one be worked on before another can be resolved?
- Can several patient problems be dealt with together?

After answering these questions, the nurse ranks the diagnoses/problems in the order in which they should be addressed. Setting priorities enables the nurse to make sure that time and energy are being directed first to the patient's

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

most important problems.

IDENTIFYING AND WRITING OUTCOMES

Learning to identify and write appropriate outcomes takes practice. The following sections will help you to identify outcomes that will maximize your effectiveness when working with patients.

Deriving Outcomes From Nursing Diagnoses/Problems

Outcomes are derived from the problem statement. For each problem in the care plan, at least one outcome should be written that, if achieved, demonstrates a direct resolution of the problem statement (Table 17-1).

Other outcomes that contribute to the resolution of the problem may be written as well. For example, for the diagnosis *Body weight problem: Overweight; etiologic factors: excessive snacking and inactivity*, in addition to the outcome "Within 12 weeks (by 12/6/25), the patient will lose 20 lb and reach target weight (122 lb)," the following goals are appropriate: "Within 3 days of teaching, the patient will identify 10 low-calorie snack foods he is willing to try; the patient will have 3-day diet recall consistent with nutritionally balanced 1,500-calorie diet; the patient will report incorporating three half-hour periods of walking at 5 miles per hour into each week." If the patient can identify low-calorie snack foods and adopt a more active lifestyle, there is a greater likelihood that he will reach his target weight, but it is entirely possible for a patient to achieve these secondary outcomes without resolving the chief problem. Remember, at least one outcome per problem statement must directly resolve the problem.

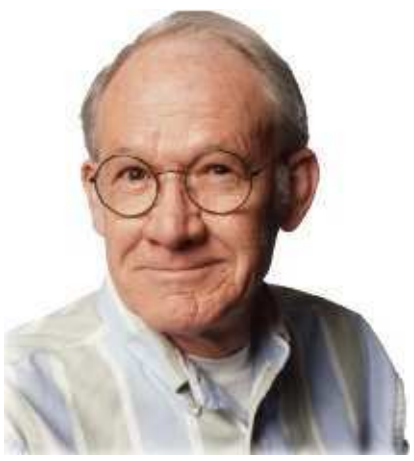


Table 17-1 Examples of Goals/Outcomes to Relieve Problems

PROBLEM STATEMENT OF THE NURSING DIAGNOSIS	RELATED PATIENT GOAL/OUTCOME
Pain	Within 8 hours, patient will report pain is absent or diminished
Nutrition Problem: More Than Body Requirements	Within 2 weeks (by 12/6/25), patient will reach target weight of 122 lb
Impaired Physical Mobility	Before discharge, patient will ambulate length of hallway independently

The **Nursing Outcomes Classification (NOC)** developed by the Iowa Outcomes Project presents the first comprehensive standardized language used to describe the patient outcomes that are responsive to nursing intervention (Moorhead et al., 2013). The current classification lists 490 outcomes with definitions, indicators, measurement scales, and supporting references. The outcomes may be used for individuals, families, or communities. Explicit linkages between the North American Nursing Diagnosis Association-International (NANDA-I) diagnoses and the NOC facilitate a comprehensive approach to care planning. Remember whenever you use standardized language to ensure that it adequately captures the uniqueness of your patients and families.

Establishing Long-Term Versus Short-Term Outcomes

Outcomes may be either long term or short term. Long-term outcomes require a longer period (usually more than a week) to be achieved than do short-term outcomes. They also may be used as discharge goals, in which case they are more broadly written and communicate to the entire nursing team the desired end results of nursing care for a particular patient. For example, two women, both 77 years of age, are on a nursing unit after undergoing similar operations for fractured left hips. One woman has spent the past 2 years in bed in a long-term care facility; the other woman fractured her hip at the YMCA, where she swims daily. Their nursing care should not be the same because it is directed toward different long-term goals, even though their short-term goals may be similar (Box 17-2).

Consider **Elijah Wolinski**, the frail, older adult with a pressure injury. The nurse might establish a long-term outcome such as, "The patient's sacral area will exhibit no evidence of a pressure injury." Short-term outcomes might include, "The patient's sacral pressure injury demonstrates an absence of purulent drainage within 1 week of initiating wound care. By week 2, the patient's pressure injury has decreased in size by 1 cm. By week 2, the patient's caregiver demonstrates measures to relieve pressure on the skin while the patient is in bed."

Determining Patient-Centered Outcomes

Alfaro-LeFevre (2020, p. 164) recommends that nurses first ask patients to describe two or three major goals they would like to achieve. Nurses then should be realistic and consider:

Box 17-2 **Examples of Long- and Short-Term Outcomes**

Patient on Bed Rest From Long-Term Care Facility

Long-Term Outcome

Mrs. Goldstein returns to the long-term care facility pain free with her incision healed and her left leg in good alignment.

Short-Term Outcomes

- Whenever observed, patient will be lying in bed with legs in correct alignment (abductor pillow in place, if ordered).
- Before discharge, Mrs. Goldstein's hip incision will show signs of healing (skin surfaces approximate, free from signs of infection—redness, swelling, heat, purulent drainage).
- Whenever observed, patient will report that comfort measures and medication are satisfactorily managing pain.

Active Patient From Private Home

Long-Term Outcome

Mrs. Silverstein returns home to her husband pain free with incision healed, fully mobile (full weight bearing on left leg), and capable of independent activities of daily living.

Short-Term Outcomes

- By 1/28/25, the patient will verbalize willingness to participate in physical therapy program.
- By 2/4/24, the patient will ambulate (with nursing assistance and walker) to bathroom (full weight bearing).
- By 2/11/24, the patient will ambulate with nursing assistance only (no walker) in her room.
- Goals for incision and pain relief same as for Mrs. Goldstein.

- Patient's health state and overall prognosis
- Expected length of stay
- Growth and development
- Patient values and cultural considerations
- Other planned therapies for the patient
- Available human, material, and financial resources
- Risks, benefits, and current scientific evidence
- Changes in status that indicate the need to modify usual expected outcomes

Moorhead et al. (2013, p. 32) recommend considering the following factors when selecting outcomes: (1) the type of health concern, (2) the nursing or medical diagnoses, (3) patient characteristics, (4) available resources, (5) patient preferences, and (6) treatment potential.

Family Involvement

One of the most important considerations in writing outcomes is to encourage the patient and family to be as involved in goal development as their abilities and interest permit. When developing patient outcomes, the nurse, patient, and family look at the problem statement of the nursing diagnosis/problem and ask, "What patient changes or outcomes will result in the prevention or resolution of this problem?" The answer, when carefully worded, becomes the patient outcome.

Using Cognitive, Psychomotor, and Affective Outcomes

Outcomes may be categorized according to the type of change needed by a patient. Cognitive outcomes describe

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

increases in patient knowledge or intellectual behaviors—for example: "Within 1 day after teaching, the patient will list three benefits of continuing to apply moist compresses to leg ulcer after discharge." Psychomotor outcomes describe the patient's achievement of new skills—for example, "By 6/12/25, the patient will correctly demonstrate application of wet-to-dry dressing on leg ulcer." Affective outcomes describe changes in patient values, beliefs, and attitudes. Difficult both to write and to evaluate, affective outcomes could be critical to the resolution of a complex patient problem—for example, "By 6/12/25, the patient will verbalize valuing health sufficiently to practice new health behaviors to prevent recurrence of leg ulcer." In this example, even if the patient intellectually grasps the reasons for taking care of her leg and can competently redress her ulcer, unless she is motivated to take care of herself, her knowledge and skills will not result in healthy outcomes. See Chapter 19 for other examples of these outcomes.

Identifying Clinical, Functional, and Quality-of-Life Outcomes

Another way to think about the types of outcomes to identify is to categorize them as clinical, functional, or quality of life. Alfaro-LeFevre (2014, p. 137) presents them as follows:

Clinical outcomes describe the expected status of health issues at certain points in time, after treatment is complete. They address whether the problems are resolved or to what degree they are improved.

Functional outcomes describe the person's ability to function in relation to the desired usual activities.

Quality-of-life outcomes focus on key factors that affect someone's ability to enjoy life and achieve personal goals.

Identifying Culturally Appropriate Outcomes

The American Nurses Association (ANA) Scope and Standards of Practice (2021) direct nurses to practice in a manner that is *congruent with cultural diversity and inclusion principles*. See Chapter 5 for a discussion of culturally appropriate care.

Identifying Outcomes Supportive of the Total Treatment Plan

When identifying outcomes, always remember that nurses nurse *people*, not problems. This means that every outcome you write should support the overall treatment plan and "make sense" in terms of the overall goals for the patient. For example, identifying nutritional outcomes may be appropriate for a patient who is losing weight, but if this patient is in a hospice and dying, this may not be an appropriate outcome if it is incompatible with the overall goal of a peaceful death with dignity.

Writing Patient-Centered Measurable Outcomes

To be measurable, outcomes should have the following:

- *Subject:* the patient or some part of the patient.
- *Verb:* the action the patient will perform.

  Verbs helpful in writing measurable outcomes include:

Define	List	Explain
Prepare	Verbalize	Select
Identify	Describe	Apply
Design	Choose	Demonstrate

- *Conditions:* the particular circumstances in or by which the outcome is to be achieved. Not every outcome specifies conditions.
- *Performance criteria:* the expected patient behavior or other manifestation described in observable, measurable terms.
- *Target time:* when the patient is expected to be able to achieve the outcome. The target time or time criterion may be a realistic, actual date or other statement indicating time, such as "before discharge," "after viewing film," or "whenever observed."

Here are two examples of properly constructed measurable outcomes:

"During the next 24-hour period, the patient's fluid intake will total at least 2,000 mL."

"At the next visit, 12/23/25, the patient will correctly demonstrate relaxation exercises."

It often helps to include special conditions when writing an outcome if this information is important for other nurses —for example, "Before discharge, the patient will ambulate independently the length of hallway and back, using a Philadelphia collar to support cervical vertebrae."

A memory jog for writing goals and outcomes is the word SMART (Doran, 1981):

S—specific

M—measurable

A—attainable

R—realistic

T—time-bound

Avoiding Common Errors in Outcomes

Common errors when writing patient outcomes include the following:

Expressing the patient outcome as a nursing intervention

Incorrect: "Offer Mr. Myer 60-mL fluid every 2 hours while awake."
Correct: "Mr. Myer will drink 60-mL fluid every 2 hours while awake, beginning 2/24/25."

Using verbs that are not observable and measurable

Incorrect: "Mrs. Gaston will know how to bathe her newborn." Verbs to be avoided when writing goals include "know," "understand," "learn," and "become aware." These verbs are too general and cannot be measured. Verbs for writing outcomes should be observable and measurable (as listed previously).
Correct: "After attending the infant care class, Mrs. Gaston will correctly demonstrate the procedure for bathing her newborn."

Including more than one patient behavior/manifestation in short-term outcomes

Incorrect: "Patient will list dangers of smoking and stop smoking."
Correct: "By next meeting, 3/11/25, the patient will (1) identify three dangers of smoking and (2) describe a plan he is willing to try to stop smoking. By 6/20/25, the patient will report that he no longer smokes."

Writing outcomes that are so vague that other nurses are unsure of the goal of nursing care

Incorrect: "Patient will cope better."
Correct: "After teaching, 10/20/25, the patient will (1) describe two new coping strategies he is willing to try and (2) demonstrate decreased incidence of previously observed ineffective coping behaviors (chain smoking, withdrawal behavior, heavy alcohol consumption)."

Ensuring Quality Outcomes

The Committee on Quality Health Care in America of the Institute of Medicine, now the National Academy of Sciences, Engineering, and Medicine (2001), in its report *Crossing the Quality Chasm*, highlights six aims to be met by health care systems with regard to the quality of care:

. *Safe:* avoiding injury
. *Effective:* avoiding overuse and underuse
. *Patient centered:* responding to patient preferences, needs, and values
. *Timely:* reducing waits and delays
. *Efficient:* avoiding waste
. *Equitable:* providing care that does not vary in quality to all recipients

Institutions measuring their achievement of these aims will welcome nursing's efforts to determine its effectiveness (Moorhead et al., 2013, p. 32).

Joint Commission National Patient Safety Goals

The Joint Commission publishes standards and requirements for Joint Commission accreditation and certification programs. Be sure to check their website (www.jointcommission.org) and pay special attention to the National Patient Safety Goals. The purpose of the National Patient Safety Goals is to improve patient safety, focusing on problems in health care safety and how to solve them. The 2020 Hospital National Patient Safety goals included (https://www.jointcommission.org/en/standards/national-patient-safety-goals/):

- Identify patients correctly
- Improve staff communication
- Use medicines safely
- Use alarms safely
- Prevent infection
- Identify patient safety risks
- Prevent mistakes in surgery

Chapter 19 describes other examples to ensure quality outcomes.

Healthy People Goals

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Healthy People identifies our nation's health improvement priorities. For more than 30 years, Healthy People has established evidence-based national health objectives with clear targets that allow us to monitor progress, motivate action, and guide efforts to improve health across the country.

With a focus on ambitious, yet achievable, 10-year goals and targets, the Healthy People 2020 initiative. Healthy People 2030 sets data driven national objectives to achieve health and well-being over the next decade. Healthy People 2030 includes 355 core- or measurable-objectives as well as developmental and research objectives. Leading health indicators (LHIs) are a small subset of high priority objectives selected to drive action toward improving health and well-being (https://health.gov/healthypeople).

- Establishes 26 Leading Health Indicators selected from high-priority objectives—the majority of which are making positive progress toward achieving their targets
- Gathers and displays the best-available evidence and data to improve public health practices and strengthen existing health policies
- Provides user-centered tools for health professionals to improve the health of their communities
- Develops a platform for the public to give input and suggest additional objectives to ensure current public health priorities are represented

IDENTIFYING NURSING INTERVENTIONS

The **Nursing Interventions Classification (NIC)** project defines a **nursing intervention** as "any treatment based upon clinical judgment and knowledge that a nurse performs to enhance patient/client outcomes" (Bulechek et al., 2013, p. 2). The NIC project further goes on to describe the types of interventions:

> The Classification includes interventions that nurses do on behalf of patients, both independent and collaborative interventions, both direct and indirect care. NIC interventions include both the physiologic (e.g., Acid–Base Management) and the psychosocial (e.g., Anxiety Reduction)…. Interventions are included for illness treatment (e.g., Hyperglycemia Management), illness prevention (e.g., Fall Prevention), and health promotion (e.g., Exercise Promotion). Most of the interventions are for use with individuals, but many are for use with families (e.g., Family Integrity Promotion) and some for entire communities (e.g., Environmental Management: Community). Indirect care interventions (e.g., Supply Management) are also included.

Carpenito-Moyet (2017a, pp. 37–38) describes how the major focus of intervention differs according to the type of nursing diagnoses or collaborative problem being addressed. For actual nursing diagnoses, interventions seek to:

- Reduce or eliminate contributing factors of the diagnosis/problem
- Promote higher-level wellness
- Monitor and evaluate status

For risk nursing diagnoses, interventions seek to:

- Reduce or eliminate risk factors
- Prevent the problem
- Monitor and evaluate status

For possible nursing diagnoses, interventions seek to:

- Collect additional data to rule out or confirm the diagnosis

For collaborative problems, interventions seek to:

- Monitor for changes in status
- Manage changes in status with nurse- and physician-prescribed interventions
- Evaluate response

Your challenge in the planning phase of the nursing process is to identify the nursing interventions most likely to achieve the outcomes. There are nurse-initiated, physician-initiated, and collaborative interventions.

Nurse-Initiated Interventions

A **nurse-initiated intervention** is an autonomous action based on scientific rationale that a nurse executes to benefit the patient in a predictable way related to the nursing diagnosis and projected outcomes. According to Alfaro-LeFevre (2014, pp. 142–143), nursing interventions are actions performed by the nurse to:

. Monitor patient health status and response to treatment
. Reduce risks
. Resolve, prevent, or manage a problem
. Promote independence with activities of daily living
. Promote optimum sense of physical, psychological, and spiritual well-being
. Give patients the information they need to make informed decisions and be independent

Nurse-initiated interventions do not require a health care provider's (or other team member's) order. Nurse-initiated interventions, such as patient goals, are derived from the nursing diagnosis/patient problem. But whereas the problem statement of the diagnosis suggests the patient goals, it is the cause of the problem (etiology) that suggests the nursing interventions (Fig. 17-3 on page 460). Effective nurses select nursing interventions that specifically address factors that cause or contribute to the patient's problems. For example, many factors may contribute to obesity, such as deficient nutritional knowledge, convenience of high-calorie fast foods, lifetime snacking habits, limited food budget, little exercise, food desert, and low self-esteem. The nurse working with a patient who wants to lose weight could attempt to deal with all these factors, but this approach would be inefficient. When a carefully developed nursing diagnosis identifies the specific factors that contribute to a particular patient's weight problem, nursing interventions can be selected to deal directly with these factors.

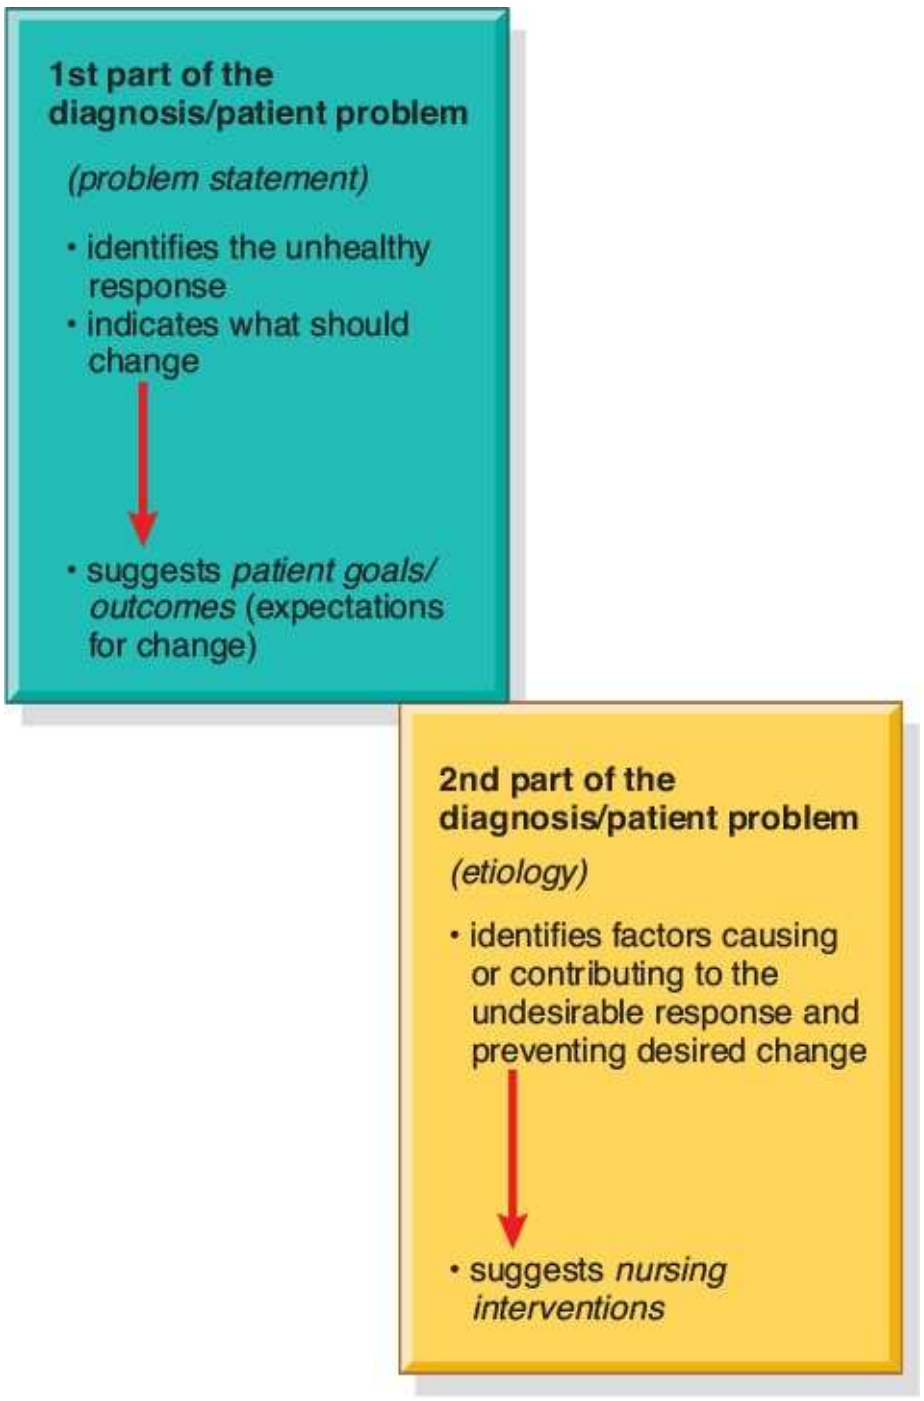

FIGURE 17-3. Deriving patient goals/outcomes and nursing orders from nursing diagnoses/problems.

Remember **Glenda Kronk**, the woman desiring to improve her fitness. Based on assessment, the nurse determines the factors that have played a role in the patient's current status, developing appropriate nursing diagnoses and outcomes from which to establish appropriate interventions. For example, if the patient has been sedentary over the past several years, interventions should focus on measures to increase the patient's activity level, thereby promoting improvement in her overall health and fitness.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Similarly, nursing interventions for a patient with the diagnostic statement *Body weight problem: Overweight; etiologic factors: lifetime snacking habits and heavy reliance on high-calorie fast foods* might include education about the fat content and calories in fast foods and exploration of ways the patient could change eating habits to eat more nutritionally balanced meals with fewer calories. Thus, the nursing approach is not the same for every patient with a weight problem. The art of thoughtful, person-centered nursing practice involves the careful identification of the specific nursing interventions needed by particular patients to meet their individual needs.

Identifying and Selecting Appropriate Nurse-Initiated Interventions

After writing the patient outcomes, the nurse identifies various nursing interventions to help the patient achieve the outcomes. The Nursing Interventions Classification (NIC), the first comprehensive, validated list of nursing interventions applicable to all settings that can be used by nurses in multiple specialties, greatly facilitates the work of identifying appropriate interventions. Go to this website to see the NIC taxonomy: https://nursing.uiowa.edu/cncce/nursing-interventions-classification-overview. Bulechek et al. (2013, p. 13) write that the selection of a nursing intervention for a particular patient is part of the clinical judgment of the nurse. They identify six factors that should be considered when choosing an intervention: (1) desired patient outcomes, (2) characteristics of the nursing diagnosis, (3) research base for the intervention, (4) feasibility for doing the intervention, (5) acceptability to the patient, and (6) capability of the nurse.

The effectiveness of the nurse is directly proportional to the nurse's knowledge of varied nursing strategies. Consider the following different nursing care options identified by three nurses when they are asked to describe nursing care for a woman 2 days after cesarean delivery who is complaining of pain in the incisional area.

Nurse A

- Check to see what type of pain medication is ordered, and give it if the time interval is sufficient.

Nurse B

- Assess the quality of the pain, and use this time to communicate support by means of expression and squeeze of hand.
- Administer analgesic if indicated.
- Assess effectiveness of the analgesic ordered.

Nurse C

- Assess quality of the pain, and explore the possibility of contributing factors such as the effects of increased gas in the abdominal area or concern about the newborn, herself, or other family members.
- Use empathic listening (possibly touch) to communicate support and to encourage the mother to share her concerns.
- Change the patient's position in bed.
- Offer a backrub.
- If appropriate, suggest activity that will distract attention from the pain (e.g., watching a film about newborn care or listening to music).
- Give the prescribed medication for pain and observe its effect.
- When administering the medication, use the power of positive suggestion to enhance its effectiveness: "This will start taking the pain away in about 10 minutes and will help you relax."

Box 17-3 Guidelines for Selecting Nursing Interventions

Nursing interventions should be:

- Valued, whenever possible, by the patient and family
- Appropriate in terms of the diagnosis/patient problem and related patient outcomes, safe, and efficient
- Consistent with research findings and standards of care
- Realistic in terms of the abilities, time, and resources available to the nurse and patient
- Compatible with the patient's values, beliefs, and cultural and psychosocial background
- Compatible with other planned therapies

It is possible that the patient simply needs her prescribed analgesic to achieve the outcome: "Patient will report minimal to no pain at assessment every 2 hours." In that case, all three nurses would be effective in meeting the patient's need for nursing care. It is highly possible, however, that the prescribed medication is not sufficient or the pain is compounded by the mother's fears about caring for her new baby or by her worries that the baby will ruin her relationship with her husband. Therefore, Nurse C, whose knowledge level is more comprehensive, is likely to be most effective in resolving the patient's problem.

The more varied the options available to the nurse, the more effective the nursing response. In different situations, a

skilled nursing procedure, the appropriate use of silence, respectful listening, humor, teaching, counseling, and touch can all be effective nursing strategies. Nurses who are merely task oriented and satisfied to meet every patient problem with a mechanical procedure are limiting their effectiveness.

When selecting nursing interventions for individual patients, use the guidelines in Box 17-3. These guidelines help ensure that the patient will achieve the outcome. Ongoing evaluation enables the nurse to determine the effectiveness of the selected interventions.

Reducing Variation

If there is one thing that systemness and the 2020 pandemic taught us, it is that we all need to quickly adopt best practices. In a 2020 viewpoint on "Choices for the 'new normal'," Donald Berwick, president emeritus of the Institute for Health Care Improvement states that clinicians in the new normal may be less tolerant of unwarranted variation in health care practice. What COVID-19 did was make all frontline caregivers seek guidance from trusted sources. "This is the way we do it here" gave way very quickly to "What are experts saying is the best course of action for all of us?" Never before has there been a greater emphasis on all professional caregivers researching and sharing best practices. Nurses have a critical role to play in researching and communicating best practices. Berwick's question is one we all need to ponder: "Will the new normal embrace global learning, shared knowledge, and trusted authority as foundations for reducing harmful, wasteful, and unscientific variation in care?" (Berwick, 2020).

If you are interested in learning about best practices, you may want to check out the American Association of Critical Care Nurses website (https://www.aacn.org/clinical-resources). There you will find:

- Practice Alerts, directives to guide evidence-based nursing practice within the context of a healthy work environment;
- CSI Innovation Projects, strategies, interventions, tools, and outcomes from successful nurse-led change initiatives; and
- Clinical Pearls and other resources.

Individualizing Evidence-Based Interventions

Nurse researchers are attempting to establish a statistical pattern for predicting the probability of success for select nursing interventions. Using the student care plan at the end of this chapter, review the scientific rationale for the selected nursing orders. You should always be prepared to explain why you are doing intervention "a" as opposed to intervention "b" or "c." You should know how likely it is that the proposed intervention will achieve the desired outcomes and what the associated risks are. Nurses should answer four key questions when determining individualized evidence-based interventions:

. What can be done to prevent or minimize the risks or causes of this problem?
. What can be done to manage the problem?
. How can I tailor interventions to meet expected outcomes?
. How likely are we to get desired versus adverse responses to the interventions, and what can we do to reduce the risks and increase the likelihood of beneficial responses?

Alfaro-LeFevre (2014, p. 148) cautions nurses using standard and electronic plans to always do this with a critical mind. Remember that you are responsible for:

- detecting changes in patient status that may contraindicate using the plan.
- using good judgment about which parts of the plan apply and which do not.
- recognizing when problems are not covered by the plan and finding other ways to address them. (Some facilities, e.g., have an additional page that can be placed on the record to address "out-of-the-box" situations.)
- adding unique patient requirements (e.g., walker) in appropriate places.

You can learn more about evidence-based practice in Chapter 2 and in the Research in Nursing and PICOT in Practice recurring displays in the clinical chapters (Units VI and VII). Competent nurses use research findings (science of nursing), experience, and knowledge of the patient (art of nursing) to help select effective nursing interventions. Consultation with nurse colleagues and continuing education also assist nurses to develop effective nursing approaches to patients' problems.

Recording Nurse-Initiated Interventions in the Patient Record

Nursing interventions describe, and thus communicate to the entire nursing staff and health care team, the specific nursing care to be implemented for the patient. Each nursing intervention should include:

- Date
- Verb: Action to be performed
- Subject: Who is to do it
- Descriptive phrase: How, when, where, how often, how long, or how much
- Signature

Well-written nursing interventions accomplish the following:

- Assist the patient to meet specific outcomes that are related directly to one outcome.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Clearly and concisely describe the nursing action to be performed (i.e., answer the questions who, what, where, when, and how).
- Are dated when written and when the care plan is reviewed.
- Are signed by the nurse prescribing the order or intervention.
- Use only those abbreviations accepted in the institution. (These are usually found in the facility's policy manual; a list of commonly accepted abbreviations appears in Chapter 20.)
- Refer the nurse to the facility's procedure manual or other literature for the steps of routine, lengthy procedures.

Here are some examples of well-stated nursing interventions:

- Offer patient 60-mL water or juice (prefers orange or cranberry juice) every 2 hours while awake for a total minimum PO intake of 500 mL.
- Teach patient the necessity of carefully monitoring fluid intake and output; remind patient each shift to mark off fluid intake on record at bedside.
- Walk with patient to bathroom for toileting every 2 hours (on even hours) while patient is awake.

Concept Mastery Alert

Outcome statements reflect the result or what to achieve; interventions state how the nurse will go about trying to achieve the result.

The set of nursing interventions written to assist a patient to meet an outcome must be comprehensive. Comprehensive nursing interventions specify what *observations* (assessments) need to be made and how often; what nursing *interventions* need to be done and when they must be done; and what *teaching*, *counseling*, and *advocacy* needs patients and families have.

Many sets of nursing interventions are inadequate because they fail to indicate the ongoing assessment priority needs for a specific problem or goal. Clearly stating assessment priorities helps all nurses to be more sensitive to important patient data.

Review the scenario for **Glenda Kronk** at the beginning of the chapter. The nurse would need to establish assessment priorities. In assisting Glenda to reach her target weight, appropriate nursing interventions might include the following: "6/17/25: Continue to assess (1) patient's motivation to participate in weight-loss program and (2) factors that positively or negatively influence weight loss."

Similarly, nurses should not assume that all patients have the same teaching needs. Many patients have an excellent knowledge base, which in some cases may be greater than that of the nurse for a particular disease. Patients who are learning to live with a chronic illness may need counseling instead of teaching. However, it is important to obtain proof of the patient's knowledge or competency before proceeding with the care plan. For example, a diabetic patient would need to state the signs and symptoms of hypo- and hyperglycemia or give a return demonstration of doing a fingerstick blood glucose test. In summary, comprehensive nursing interventions relate to individual patient needs.

Physician-Initiated and Collaborative Interventions

An intervention is initiated by a physician in response to a medical diagnosis but is carried out by a nurse in response to a doctor's order. For example, a physician examining a patient brought into the emergency department after a motor vehicle accident might ask the nurse to administer a medication to relieve pain and to schedule the patient for radiographs and other diagnostic tests. The nurse who performs these interventions is implementing **physician-initiated interventions**. Both the physician and nurse are legally responsible for these interventions, and nurses are expected to be knowledgeable about how to execute these interventions safely and effectively. Nurses who question the appropriateness of physician-initiated interventions are legally responsible to seek clarification of the order with responsible parties. Under no circumstances should a nurse implement a questionable intervention, even at the urging of a physician or other professional. Chapter 7 addresses nurses' legal responsibility for their actions.

Nurses also carry out treatments initiated by other providers such as pharmacists, respiratory therapists, or physician

assistants; these are **collaborative interventions**. For example, nurses caring for a patient after a motor vehicle accident may eventually implement interventions written by a physical therapist, occupational therapist, or other member of the health care team.

Structured Care Methodologies

Efforts to standardize nursing care have taken different forms. Popular past approaches have included procedures (1960s), standards of care (1970s), algorithms (1980s), and clinical practice guidelines (1990s). Each of these approaches aimed to help the nurse identify and select interventions that produce optimal care, reduce legal risks, and lower health care costs.

Procedure: A set of how-to action steps for performing a clinical activity or task

Standard of care: A description of an acceptable level of patient care or professional practice

Algorithm: A set of steps that approximates the decision process of an expert clinician and is used to make a decision; these clinical rules are typically embedded in a branching flow chart

Clinical practice guideline: A statement or series of statements outlining appropriate practice for a clinical condition or procedure

National guidelines such as those published by the U.S. Agency for Health Care Research and Quality (AHRQ; http://www.ahrq.gov) and the Cochrane Library (http://www.cochranelibrary.com) are generally based on the latest, most comprehensive scientific evidence and expert analysis. They provide standards for delivering and evaluating care for patients with the same diagnosis. Box 17-4 compares structured care methodologies. Additional examples are provided in Chapter 19.

Classification Systems

One of the first things you will need to do when beginning a new practice site is to learn about the classification system used in that setting.

Omaha System

The Omaha System (OS) is one of the oldest of the ANA-recognized standardized terminologies describing and measuring the impact of health care services. It is a research-based, comprehensive, standardized taxonomy or classification that exists in the public domain. It is designed to enhance practice, documentation, and information management. It is intended for use across the continuum of care for individuals, families, and communities who represent all ages, geographic locations, medical diagnoses, socioeconomic ranges, spiritual beliefs, ethnicity, and cultural values. It was developed in the 1970s by the Visiting Nurse Association of Omaha to document and manage home care services, but it is now widely applied across health care disciplines and settings. The OS has three aspects:

Box 17-4 Structured Care Methodologies

Algorithm

- Useful in management of high-risk subgroups within the cohort; may be "layered" on top of a pathway to control care practices that are used to manage a specific problem
- Binary decision trees that guide stepwise assessment and intervention
- Intense specificity; no provider flexibility
- May use analytical research methods to ensure cause and effect

Critical Pathway

- Represents a sequential, interdisciplinary, minimal practice standard for a specific patient population
- Provides flexibility to alter care to meet individualized patient needs
- Abbreviated format, broad perspective
- Phase or episode driven
- Ability to measure cause-and-effect relationship between pathway and patient outcomes prohibited by lack of control; changes in patient outcomes directly attributable to the efforts of the collaborative practice team

Guideline

- Broad, research-based practice recommendations
- May or may not have been tested in clinical practice
- Practice resources helpful in construction of structured care methodologies
- No mechanism for ensuring practice implementation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Order Set

- Preprinted provider orders used to expedite the order process after a practice standard has been validated through analytical research
- Complements and increases compliance with existing practice standards
- Can be used to represent the algorithm or protocol in order format

Protocol

- Prescribes specific therapeutic interventions for a clinical problem unique to a subgroup of patients within the cohort
- Multifaceted; may be used to drive practice for more than one discipline
- Broader specificity than an algorithm; allows for minimal provider flexibility by way of treatment options
- May be "layered" on top of a pathway

Source: Agency for Health Care Policy and Research's (now Agency for Healthcare Research and Quality) Clinical Practice Guideline Development, AHCPR program note in Publication 93-0023, 1993.

. Structure: characteristics of the care providers, their tools and resources, and the physical/organizational setting)
. Process: both interpersonal and technical aspects of the treatment process
. Outcome: change in the patient's symptoms and functioning

The OS also has three steps: problem, intervention, and outcome. The four intervention categories are health teaching, guidance, and counseling; treatments and procedures; case management; and surveillance. Current users and their sites now include the continuum of care: home care, public health, and school health practice settings; nurse-managed center staff; hospital-based and managed care case managers; educators and students; occupational health nurses; faith community staff; acute care and rehabilitation hospital/long-term care staff; researchers; members of various disciplines; and computer software vendors. The majority of OS users are located in the United States (http://www.omahasystem.org/overview.html).

Clinical Care Classification System

The Clinical Care Classification (CCC) System was founded by Dr. Virginia K. Saba who has pioneered and spearheaded Nursing Informatics nationally and internationally (see Chapter 21). The CCC System (V-2.5) offers a new approach to documenting nursing practice in an electronic health record (EHR). It consists of a standardized framework representing three unique levels:

. 176 Nursing Diagnoses
. 804 Nursing Intervention/Actions
. 528 Nursing Outcomes, each of which are classified by 21 Care Components representing four Healthcare Patterns to form one system—the CCC System (https://www.sabacare.com/framework/).

Consulting

A nurse designing the care plan may discover that more information is needed about the nature of the problems underlying the need for nursing or about specific interventions. **Consultation**, a process in which two or more people with varying degrees of experience and expertise discuss a problem and its solution, often proves helpful. Nurses might consult with nurse specialists and other members of the health care team, including health care providers, nutritionists, social workers, therapists, pastoral caregivers, and ethicists (Fig. 17-4). Consultations are a valuable means for nurses to expand their nursing knowledge and repertoire of effective strategies.

QSEN TEAMWORK AND COLLABORATION

It is always important for nurses to know their own strengths, limitations, and values when identifying the best interventions to address patient problems and to value the perspectives and expertise of all health team members. Knowing when to consult and doing so is essential to excellent practice. It is never too early to begin learning who and what your best resources are.

FIGURE 17-4. Consulting with a nursing colleague or other member of the health care team can help the nurse develop an effective nursing care plan. (Used with permission from Shutterstock. *Photo by B. Proud*.)

Review the Reflective Practice box (on page 451) describing **Darla Jefferson**. The nurse would consult other health care team members for assistance. For example, the nurse might consult social services for assistance with drug treatment and rehabilitation. Should the patient decide to keep her baby, social services also would be helpful, such as with obtaining food stamps and infant formula through government programs, appropriate housing, and follow-up in the community. A consultation with a nutritionist would be helpful prenatally to help Darla meet the requirements for herself and her fetus, and also postpartum to ensure that the infant is receiving adequate nutrition to grow and develop.

DEVELOPING EVALUATIVE STRATEGIES

Well-written outcomes define evaluative strategies to be used by the nurse. Patient outcomes are meaningless unless nurses evaluate the patient's progress toward their achievement. The nurse records the date the outcome was written and the date it is achieved. An evaluative statement (Box 17-5) includes a statement about achievement of the desired outcome (met, partially met, not met) and lists actual patient behavior as evidence supporting the statement. If the plan is not achieved, recommendations for revising the care plan are included in the evaluative statement. Chapter 19 deals specifically with the evaluative component of the nursing process.

COMMUNICATING AND RECORDING THE NURSING CARE PLAN

The **nursing care plan** (patient care plan) is the written guide that directs the efforts of the nursing team working with the patient to meet their health goals. It specifies nursing diagnoses/problems, outcomes, and associated nursing interventions. Well-written care plans offer many benefits to the patient, nurse, nursing unit, nursing administration, and nursing profession. Primarily, nursing care plans ensure that the nursing team works efficiently to deliver holistic, goal-oriented, person-centered care to patients.

Box 17-5	Evaluative Statement

Documents that patient has met, partially met, or not met the goal/outcome.

Goal/Outcome Statement

Beginning 6/8/25, the patient will ambulate half the length of hallway with assistance three times daily.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Evaluative Statement

6/8/25—Goal partially met; patient refused to ambulate in the morning but did walk to the bathroom once in the afternoon with the assistance of one nurse.

Recommendation: Review reason for progressive ambulation with patient; assess motivation to increase independence.

—M. Stenulis, RN

A well-written nursing care plan:

- Represents an effective philosophy of nursing and advances nursing's four aims: promoting health, preventing disease and illness, promoting recovery, and facilitating coping with altered functioning
- Is prepared by the nurse who best knows the patient and is recorded on the day the patient presents for treatment and care, according to facility policy, with modifications to the initial plan signed and dated
- Is responsive to the individual characteristics, values and needs of the patient, and is culturally appropriate
- Clearly identifies the nursing assistance the patient needs and nursing's collaborative responsibilities for fulfilling the medical and interdisciplinary care plan (clearly specifies nursing diagnoses/problems, patient outcomes, nursing interventions, and evaluative strategies)
- Directs the nurse's assessment priorities, caregiving behaviors, and teaching, counseling, and advocacy behaviors
- Is based on scientific principles and incorporates findings of nursing research
- Meets the developmental, psychosocial, and spiritual needs of the patient, as well as the patient's physiologic needs
- Is updated to reflect changes in the patient's status and related needs for nursing care
- Addresses the discharge needs of the patient and family
- Provides for as much patient and family participation as possible
- When appropriate, is compatible with the medical care plan and that of the interdisciplinary team
- Creates a record that can be used for evaluation, research, reimbursement, and legal purposes

Many suggestions for care plans appear in the nursing literature. Each school of nursing and each health care institution and facility has its own format, which may reflect a particular nursing theory. Common to all formats is a minimum of three columns for documenting nursing diagnoses, patient outcomes, and nursing interventions. Formats vary in the ways assessment data and the nursing evaluation are addressed. Many facilities now post an abbreviated care plan on the wall in the patient's room highlighting priority outcomes.

Institutional and Facility Care Plans

The Joint Commission requires health care institutions and facilities to formulate, maintain, and support a patient-specific plan for care, treatment, and rehabilitation.

Types of Nursing Care

In most institutions and facilities, care plans, regardless of their format, communicate directions for three different types of nursing care: nursing care related to basic human needs, nursing care related to nursing diagnoses/problems, and nursing care related to the medical and interdisciplinary care plan.

NURSING CARE RELATED TO BASIC HUMAN NEEDS

The plan should concisely communicate to caregivers the data about the patient's usual health habits and patterns, obtained during the nursing history, that are needed to direct daily care. For example, it is important to know whether a toddler is toilet trained and what words the child uses to indicate the need to void or defecate. Directives about the patient's usual health habits and patterns might be modified by current treatment orders, such as an order to fast for a diagnostic procedure or to limit or increase activity. This information is useful to caregivers only if it is kept current as the patient's condition changes. Any nurse should be able to find in the care plan the instructions needed to provide competent care.

NURSING CARE RELATED TO NURSING DIAGNOSES/PROBLEMS

The plan contains outcomes and nursing interventions for every nursing diagnosis/problem, as well as a place to note the patient's responses to care. This section is the heart of the nursing care plan because it represents the independent component of nursing practice. When well developed, it demonstrates the nurse's clinical competence (knowledge of the science of nursing), sensitivity to the individual needs of the patient, and creativity in mobilizing the resources of the patient and the caregiving team to meet the patient's health needs.

NURSING CARE RELATED TO THE MEDICAL AND INTERDISCIPLINARY CARE PLAN

The care plan also records current medical orders for diagnostic studies and treatment and specified related nursing care.

Formats for Care Plans

A great variety of formats are used to communicate care plans. In addition to traditional written care plans, you should

be familiar with the following.

COMPUTERIZED CARE PLANS

Nurses now often use **computerized nursing care plans** as part of the electronic medical record. The benefits of computerized plans include ready access to a large knowledge base; improved record keeping and a resulting improvement in audits and quality assurance; documentation by all members of the health care team with printouts for the patient's record and for change-of-shift reports; and less time spent on paperwork. One nurse researcher, however, has studied a potential negative impact of computerized plans on the professionalization of staff nurses. Harris (1990) cautions that computerized systems for patient care planning and the larger systems in which they are embedded contribute to the loss of autonomy, loss of individualization of care, and loss of nursing expertise. Individual nurses, as well as researchers, need to respond to this challenge from Harris (1990, p. 73): "Does a lot of nursing time spent in procedural, rule-governed, step-by-step thinking processes destroy part of the nurse's ability to care, to empathize, to intuit, to gain insight, to function in the expert mode?"

CONCEPT MAP CARE PLANS

A concept map care plan is a diagram of patient problems and interventions. Your ideas about patient problems and treatments are the "concepts" that are diagrammed. These maps are used to organize patient data, analyze relationships in the data, and enable you to take a holistic view of the patient's situation (Schuster, 2016). Examples of concept map care plans are shown in Chapters 13 and 14 and throughout the text.

CHANGE-OF-SHIFT REPORTS

Chapter 12 describes the importance of critical patient information being communicated with each patient transfer or "hand-off." This includes what happens each time nurses finish their shift and hand off patients to other nurses. Many facilities have developed forms to facilitate this exchange of information, including the Situation-Background-Assessment-Recommendation/Introduction-Situation-Background-Assessment-Recommendation-Question and Answer (SBAR/ISBARQ) formats described in Chapters 8, 12, and 20. Three advantages of using a standardized hand-off tool are:

. Helps you get organized
. Prevents omissions of key information that must be communicated
. Promotes dialogue and critical thinking between caregivers

See Figure 17-5 for a standardized hand-off tool different from the SBAR. As you rotate through different clinical facilities, pay attention to their policies and procedures for hand-offs, and follow them carefully.

MULTIDISCIPLINARY (COLLABORATIVE) CARE PLANS

Clinical pathways (critical pathways, CareMaps) are tools used in case management to communicate the standardized, interdisciplinary care plan for patients. Case management is a health care delivery system intended to provide high-quality, cost-effective care for individuals, families, and groups. The emphasis is on clearly stating expected patient outcomes and the specific times within which it is reasonable to achieve these outcomes. Chapter 20 provides examples of how critical pathways are used with select documentation tools in a computerized system.

Student Care Plans

The care plans that students are required to develop are often more detailed than those used in practice settings. The aim is to assist you to assimilate each of the five phases of the nursing process. Although care plan formats vary among different nursing programs, most are designed so that the student systematically proceeds through the interrelated steps of the nursing process. Many use a five-column format. See the accompanying poem, Her First Nursing Care Plan.

Poetry Nook

Her First Nursing Care Plan

Amy Haddad, PhD, RN

She plans her care, cares about her plan
that speaks in imperatives with an authority
she does not own. She plans to watch, count, ease,
flush, remove, monitor, offer, relieve, be
there, listen, encourage, pray, prevent, provide

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

care to every system in the human body.
She is hungry for the treat of praise, “Good work!”
that follows the trick of a perfect care plan.
The patient is the notepaper on which she writes.
He is young, a husband, a father,
wiped out (not a nursing term)
from surgery for stomach cancer. The word,
metastatic in the doctor’s notes is Greek
to her. She misspells it—*metastes*—cannot
grasp the implications, instead she includes
all the organs the cancer touched on its clockwise
march around his abdomen. The strange terms—
omentum, celic gutter, hepatic flexure—
entrance her. She looks in her anatomy
book to find where the organs rest in case
her teacher asks. Her plan is filled with problems
the cancer creates during her shift.
She worries a bit no one has told
the patient what *metastes* means. Certain
it is not her place to tell such a truth,
she sticks to her plan.

Not part of the Permanent Medical Record: 2018-2019

FIGURE 17-5. Nurse-to-nurse shift reports are essential elements of care coordination. (Reprinted with permission, Inova Health System Foundation, Falls Church, VA.)

The sample student care plan shown in Box 17-6 (on pages 468–469) demonstrates a plan developed for a 72-year-old woman admitted to the hospital after experiencing a ministroke (i.e., brain attack, transient ischemic attack) at home. Her condition is stable, and the three prioritized diagnoses written in the plan address her inability to deal with this new medical diagnosis and to prevent a major stroke (high priority), ineffective coping (medium priority), and constipation (low priority).

Box 17-6	Sample Student Care Plan N.B.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Assessment/Diagnosis	Goal/Outcome	Nursing Orders	Scientific Rationale	Evaluation
Subjective data: "Will I get a stroke now? I don't think I could handle that." "How can I help myself prevent it?" *Objective data:* Admitting diagnosis: TIA BP: 184/120 *Strengths:* Past pattern of adhering to prescribed health behaviors.	Before discharge, the patient will: • Describe the terms *TIA* and *stroke,* identifying the underlying disease process, causes, symptoms, and treatment	Assess what the patient knows about TIA and stroke (correct any misinformation). Assess learning needs, readiness to learn, and factors that will influence learning. Plan teaching and learning sessions to involve family members designated by patient. Include in the teaching plan a description of TIA and stroke and the underlying disease process, causes, symptoms, and treatment plan.	Each person's learning needs are different; each person learns in their own unique way; learning is dependent on readiness. The more support people knowledgeably committed to the care plan, the greater the probability the patient will achieve goals. New self-care behaviors are dependent on knowledge.	9/10/25—Outcome not met. Patient says her head is "too old" to learn all this stuff. Equates stroke with death. *Revision:* Reteach content in simpler terms. Reassess learning readiness. *—M. Foley, SN*
Health Problem: Impaired Health Maintenance Response to TIA and Stroke Prevention ***Etiologic factor:*** knowledge deficit.	After discussion with the health care provider and nurse, the patient will: • Correctly describe the treatment plan: • Medications (drugs, intended effect, dose, time, route) • Dietary modifications • Exercise prescription • Signs and symptoms to report • Follow-up appointment date	After the treatment plan has been developed, make sure the patient and family can restate it (teaching) and value the prescribed lifestyle modification (counseling).	New self-care behaviors are dependent on motivation. Unless the patient is committed to stroke prevention and values this outcome, she will not follow the treatment plan.	9/10/25 Too early to evaluate. *—M. Foley, SN*
Subjective data: Husband died 8 months ago; moved in with daughter 6 months ago after selling family home. Daughter reports mother had been a very independent, strong woman in the past—seemed to "crumple" after husband's death. History of headaches. *Objective data:* Clutches daughter's hand. *Strengths:* History of handling life stressors well. *Limitations:* In the past, her husband was her primary support.	Beginning 9/7/25, the patient will: • Verbalize her feelings related to the loss of her husband, loss of family home, loss of health • Identify coping patterns that have helped her in the past • Identify three personal strengths and three outside supports that will help her now	Once during each shift, primary nurse should sit at patient's bedside for at least several minutes to communicate caring and to explore with the patient her current stressors and the adequacy of her coping response. • Assess factors compounding her losses. • Reinforce her personal strengths and support systems; counsel her to tap into these now. • Suggest local support groups, if indicated. Primary nurse to explore with daughter, Lisa, how her mother's moving in with her has affected the family. Recommend support systems.	The nurse's unhurried, attentive, and caring presence communicates to the patient that she is important to the nurse and that the nurse values her well-being. It is an invitation to the patient to become actively involved in recovery. Also, it is logical to explore adequacy of past and current coping mechanisms before suggesting new approaches. Adult children of aging parents frequently experience overwhelming stress as they try to deal with their own and their parents' problems. Supporting this family is supporting the patient indirectly.	9/10/25 Outcome partially met. Patient speaks freely about how much she misses her husband and how fearful this hospitalization makes her. When asked about living with her daughter, she becomes uncharacteristically quiet. *—M. Foley, SN* 9/10/25 Outcome met. Patient talks about how everything seemed better in the past after she talked it over with her husband and God. *—M. Foley, SN* 9/10/25 Outcome not met. Patient couldn't think of anything about herself that is healthy or strong. Says "maybe" her family can help her now. *Revision:* Counsel regarding personal strengths. Help her to experience them. *—M. Foley, SN* 9/11/25 Too early to evaluate. *—M. Foley, SN*
Health Problem: Coping Impairment ***Etiologic factors:*** illness, recent death of husband, and relocation with daughter.	Before discharge, the patient will: • Verbalize that she feels "okay" (sufficiently in charge of her life) about returning home			
Subjective data: "I move my bowels every 2 or 3 days; get constipated at least once a week. Often Ducolax or Metamucil helps." "I drink plenty of fluids and eat fruits and vegetables." History of hemorrhoids secondary to straining. *Objective data:* No bowel movement in past 4 days. On bed rest since hospitalized. ***Health Problem:*** Constipation ***Etiologic factors:*** decreased physical activity and long-term laxative use (Ducolax, Metamucil).	Beginning 9/7/25, the patient will: • Pass soft, formed stool every 1 to 3 days without use of laxatives By 9/10/25, the patient will: • Verbalize the importance of the following natural aids to bowel elimination: • Daily intake of foods high in bulk • Daily fluid intake of 8 to 10 glasses • Regular time for elimination • Daily physical exercise: walking	Monitor bowel elimination patterns; identify causative factors of constipation and successful corrective measures. Explain the importance of adhering to a regular time for defecation (patient suggests after breakfast)—adhere to this in the hospital. When given medical clearance, assist patient with progressive ambulation. Recommend that she include brisk walking into daily health habits (build strength to 20- to 30-minute brisk walk daily). Explain the long-term effects of laxative abuse on the bowel, and discourage use of laxatives. Reinforce the patient's fluid intake and ingestion of high-bulk foods, such as fresh fruits and salad.	This patient's elimination problems will not be resolved until all the specific causes of her constipation and successful corrective measures are identified. Needs to be an ongoing assessment priority. This encourages positive use of circadian rhythms. Peristalsis is stimulated by physical exercise. Laxative abuse leads to decreased peristaltic response to food and loss of intestinal tone. Commenting on these positive self-care behaviors reinforces them.	9/10/25 Outcome partially met. Soft, formed stool passed every 2 to 3 days with aid of docusate. *—M. Foley, SN* 9/10/25 Outcome met. Patient correctly related value of four natural aids to elimination. Questions whether she will be strong enough to walk. *Revision:* Encourage assisted ambulation. *—M. Foley, SN*

Assessing

The student records the assessment data that led to the determination of each diagnosis in the Assessment/Diagnosis column. Recording these data helps to link specific defining characteristics with diagnostic problem statements.

Diagnosing/Problem Identification

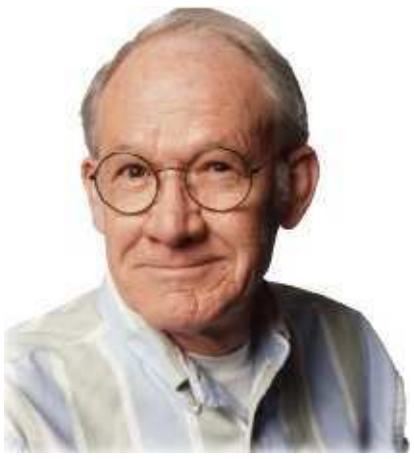
Nursing diagnoses/problems are recorded in the Assessment/Diagnosis column in a prioritized list beginning with the top-priority problem. For each diagnosis/problem, a clear and concise problem statement is followed by an etiology statement that identifies specific contributing factors.

Outcome Identification and Planning

The outcome identification and planning column (Goal/Outcome column) contains the expected changes in patient health status or in patient behaviors (i.e., patient outcomes). If achieved, these changes resolve the problem statement in the nursing diagnosis.

Implementing

Sets of nursing orders that describe specific nursing interventions are written for each patient outcome. (Refer to the Nursing Orders column in Box 17-6 on pages 468–469.) These orders specify what nursing interventions are to be performed, how they are to be performed, when they are to be performed, and who is to perform them. In many nursing programs, students are asked to document the source of their proposed nursing interventions. Although students may be able to "pull from their head" some nursing strategies, developing the practice of consulting the nursing literature is a sure means to increase nursing knowledge. Some programs also require students to provide a scientific rationale for the interventions they propose, as shown in Box 17-6 (on pages 468–469). A succinct rationale statement demonstrates that the student is deliberately choosing the nursing intervention because of its high probability to effect the desired change.



Evaluating

Incorporating evaluative statements in the care plan clearly communicates the message that nursing care is never complete until achievement of patient outcomes is evaluated. For examples, see the Evaluation column in Box 17-6 (on pages 468–469). Just as some say that teaching does not occur if learning does not take place, so nursing care is incomplete if the desired patient goals are not achieved.

PROBLEMS RELATED TO OUTCOME IDENTIFICATION AND PLANNING

Problems commonly encountered while developing nursing care plans include failure to involve the patient in the planning process, insufficient data collection, use of inaccurate or insufficient data to develop nursing

diagnoses/problems, outcomes that are stated too broadly, outcomes that are derived from poorly developed nursing diagnoses, failure to write nursing orders clearly, written nursing orders that do not resolve the problem, and failure to update the care plan.

Recall **Elijah Wolinski**, the frail, older adult with a pressure injury. Since the nurse is providing care in the patient's home, a written care plan is extremely important because more than one caregiver may be involved in the patient's care. In addition, the nurses caring for Mr. Wolinski must update the plan regularly to ensure that, regardless of who is providing the care, the correct care is given consistently.

A FINAL WORD ABOUT STANDARDIZED LANGUAGES AND HOLISTIC, PERSON-CENTERED CARE

Moorhead et al. (2013, p. 3) lament that while nurses' clinical-reasoning and decision making skills are integral to quality health care and account for much of the health care system "safety net," little attention has been focused on the outcomes of nursing interventions. They write that, as part of improving health care quality and safety, "it is imperative that nursing define its interventions and outcomes and that these standardized nomenclatures be included in clinical nursing information systems and in large data sets used for systematic analysis."

The use of NIC (Bulechek et al., 2013, p. vi):

- helps demonstrate the impact that nurses have on the system of health care delivery
- standardizes and defines the knowledge base for nursing curricula and practice
- facilitates the appropriate selection of a nursing intervention
- facilitates communication of nursing treatments to other nurses and other providers
- enables researchers to examine the effectiveness and cost of nursing care
- assists educators to develop curricula that better articulate with clinical practice
- facilitates the teaching of clinical decision making to novice nurses
- assists administrators in planning more effectively for staff and equipment needs
- promotes the development of a reimbursement system for nursing services
- promotes the development and use of nursing information systems
- communicates the nature of nursing to the public

As you can see, there are numerous reasons to use standardized language. As nurses, however, we must always remember that our primary commitment is to patients, not to standardized language. Our focus must always be on ensuring that the nursing care plan accurately captures the diagnoses and problems of the very real patient with whom we are planning care and those interventions most likely to resolve those problems. If you have established a successful partnership with the patient and family, they should be able to read the care plan and say, "Wow, you really captured our priorities!"

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in outcome identification and planning, reflect on your experiences—both successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following during the planning phase of the nursing process:

- Did your preparation for partnering with the patient and family to identify outcomes and plan care enable you to feel confident in your ability to identify pertinent outcomes, select evidence-based interventions, and communicate the care plan? Did you inspire the patient's confidence and trust? Did you seek help if you were unsure about how to identify pertinent outcomes or select evidence-based interventions?
- How confident are you that, once implemented, this plan will address the clinical, functional, and quality-of-life concerns of the patient? How can you become more familiar with the many outcomes and interventions that may be

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

applicable for future patients?
- Were you aware of any personal stereotypes or prejudices that may have negatively influenced this clinical encounter? If yes, how did you address them?
- Was the patient's and family's participation in the process at an optimal level? How might you have better engaged the patient and family? Does the care plan accurately reflect patient priorities and preferences? To what degree do you think the patient's participation in planning will influence the achievement of outcomes?

Perhaps the most important question to reflect on is: Are your patients/caregivers better for having had *you* share in the critical responsibility of partnering with them to identify outcomes and plan the care that will result in them achieving these outcomes? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Write diagnostic statements for three patients experiencing obesity, and make sure that the etiologies for the problem statement differ. Describe how these different etiologies result in different care plans.

. Use one of the nursing diagnoses/problems from Exercise 1 and write related cognitive, psychomotor, and affective goals for this patient. Explain the different purposes of each type of goal and why it may be necessary to include all three to resolve a patient problem successfully.

. An alert 82-year-old widow who has a history of unsafe behaviors has recently been discharged from the hospital to her home. Caregivers attempted to secure her consent to be transferred to a long-term care facility, but she flatly refused. Responsible for her home care, you list Risk for Injury as a priority diagnosis/problem. First, list the nursing measures that you believe are most likely to achieve the outcome of preventing injury. Then talk with several other students to compare your lists of interventions and the evidence that supports each, and discuss how practicing nurses can be sure they select the best nursing interventions for each expected patient outcome.

. You learn that the patient you will be caring for tomorrow has lymphedema in both legs and is newly admitted to the hospital. You don't know anything about lymphedema. What resources will you consult to prepare yourself to identify actual and potential diagnoses/problems, outcomes, and interventions? Share this exercise with another student and compare the lists you generate.

PRACTICING FOR NCLEX

. A nurse is planning care for a patient admitted to the hospital for treatment of a drug overdose. What actions will the nurse take during the outcome identification and planning step of the nursing process? Select all that apply.

a. Formulating nursing diagnoses
b. Identifying expected patient outcomes
c. Selecting evidence-based nursing interventions
d. Explaining the nursing care plan to the patient
e. Assessing the patient's mental status
f. Evaluating the patient's outcome achievement

. Nurses on a hospital unit work to improve staff communication, as outlined in The Joint Commission's National Patient Safety Goals. What process will best provide for continuity of the plan of care?

a. Checking two patient identifiers, such as name and date of birth, prior to administering medications
b. Ensuring two nurses check doses of high-risk medications such as anticoagulants or insulin
c. Giving handoff report in the patients' rooms to update the next nurse on the plan of care
d. Obtain a patient sitter for a confused individual who has fallen trying to get out of bed

. A nurse on a mother–baby unit engages in informal planning while providing ongoing nursing care. What actions are included in this type of planning? Select all that apply.

a. Sitting down with a patient and prioritizing existing diagnoses
b. Assessing a woman for postpartum depression during patient education
c. Planning interventions for a patient with a risk for bleeding
d. Taking time to speak with a new mother who just received bad news
e. Reassessing a patient who reports their pain medication is not working
f. Coordinating home care for a patient being discharged later today

. To plan the day, a nurse is prioritizing patient diagnoses according to Maslow's hierarchy of human needs. What patient problem will the nurse address first?

a. Altered body image perception
b. Impaired gas exchange
c. Grief

d. Situational low self-esteem

. Nurses on an oncology unit plan to adopt use of critical pathways for patients receiving chemotherapy. What positive features of this system will the nurses anticipate? Select all that apply.

a. Accessible computerized practice standards, easily individualized for patients
b. Binary decision tree for stepwise assessment and intervention
c. Ability to measures the cause-and-effect relationship between pathway and patient outcomes
d. Research-based practice recommendations that may or may not have been tested in clinical practice
e. Preprinted provider prescriptions, using standards validated through research, to streamline care
f. Outcomes with suggested time frames for achievement

. A nurse is developing outcomes in the affective domain for a patient with a foot ulcer related to diabetes. Which outcome best addresses this domain?

a. Within 1 day after teaching, the patient will list three benefits of continuing to apply moist compresses to foot ulcer after discharge.
b. By 6/12/25, the patient will correctly demonstrate application of wet-to-dry dressing on the foot ulcer.
c. By 6/19/25, the patient's pressure ulcer will decrease in size from 3 to 2.5 inches.
d. By 6/12/25, the patient will verbalize they value their health sufficiently to control diabetes and prevent recurrence of diabetic ulcers.

. A nurse is developing a clinical outcome for a patient who is an avid runner and is recovering from a stroke resulting in right-sided paresis. Which clinical outcome is most appropriate to include in the care plan?

a. After receiving 3 weeks of physical therapy, patient will demonstrate improved movement on the right side of her body.
b. By 8/15/25, patient will be able to use right arm to dress, comb hair, and feed herself.
c. Following physical therapy, patient will begin to gradually participate in walking/running events.
d. By 8/15/25, patient will verbalize feeling sufficiently prepared to participate in running events.

. A nurse is caring for a patient with dehydration who has a prescription to encourage oral fluids. Which outcome statement will best direct nursing interventions?

a. Offer patient 60 mL of fluid every 2 hours while awake.
b. During the next 24-hour period, patient's fluid intake will total at least 2,000 mL.
c. Teach the patient the importance of drinking enough fluids to prevent dehydration by 1/15/25.
d. At the next visit on 12/23/24, patient will know to drink at least 3 L of water per day.

. A nurse is writing outcomes for a patient admitted with a cardiac condition causing fluid overload and edema. Which reflects an appropriately worded outcome?

a. Offer to elevate the patient's legs on a stool while out of bed
b. Patient will restrict fluids to 1,500 mL per 24-hour period
c. Monitor the patient's intake and output
d. Weigh the patient each morning prior to breakfast

. A nursing student is presenting their concept map care plan for a patient with sickle cell anemia in post-conference. How does the student best describe the "concepts" that are being diagrammed in the plan?

a. Protocols for treating the patient's medical problem
b. Evidence-based treatment guidelines
c. Synthesis of the patient's problems and treatment
d. Clinical pathways reflecting evidence-based treatment for sickle cell anemia

. A nurse is updating the plan of care with nurse-initiated interventions. Which intervention is appropriate to include?

a. Administering acetaminophen for a headache
b. Offering emotional support to a patient
c. Consulting with a physical therapist
d. Attending a team meeting for care planning

ANSWERS WITH RATIONALES

. **b, c, d.** During the outcome identification and planning step of the nursing process, the nurse, patient, and family collaborate to establish priorities and identify and write expected patient outcomes. The nurse selects evidence-based nursing interventions, and communicates the care plan. These steps may overlap; however, formulating and validating nursing diagnoses are typically performed during the diagnosing step. Assessing mental status is part of the assessment step, and evaluating patient outcomes occurs during the evaluation step of the nursing process.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

. **c.** One of the published standards and requirements for accreditation and certification required by The Joint Commission is to "improve staff communication." Communicating the plan of care with the patient and oncoming and off going nurses meets this goal. Using patient identifiers relates to the goal of safely identifying patients, checking high-risk medications relates to decreasing medication errors, and obtaining a patient sitter relates to general safety and fall reduction.

. **b, d, e.** Informal planning is a link between identifying a patient's strength or problem and providing an appropriate nursing response, often while rearranging priorities. Examples of this include the nurse integrating assessment for postpartum depression during patient care, providing a therapeutic presence for a patient who received bad news, or reassessing a patient for pain during rounding. Formal planning involves prioritizing diagnoses, formally planning interventions, and coordinating the home care of a patient being discharged.

. **b**. Because basic needs must be met before a person can focus on higher ones, Maslow's hierarchy of needs sets the priorities as: (1) physiologic needs, (2) safety needs, (3) love and belonging needs, (4) self-esteem needs, and (5) self-actualization needs. Answer (b) is an example of a physiologic need, (a and d) are examples of a self-esteem need, and (c) is an example of a love and belonging need.

. **a, c, f.** Critical pathways represent a sequential, interdisciplinary, minimal practice standard for a specific patient population, that provide flexibility to alter care to meet individualized patient needs. They provide the ability to measure a cause-and-effect relationship between pathway and patient outcomes. An algorithm is a binary decision tree that guides stepwise assessment and intervention with intense specificity and no provider flexibility. Guidelines are broad, research-based practice recommendations that may or may not have been tested in clinical practice, and an order set is a preprinted provider order used to expedite the order process after a practice standard has been validated through analytical research.

. **d.** Affective outcomes describe changes in patient values, beliefs, and attitudes. Cognitive outcomes (a) describe increases in patient knowledge or intellectual behaviors; psychomotor outcomes (b) describe the patient's achievement of new skills; and (c) is an outcome describing a physical change in the patient.

. **b.** Clinical outcomes describe the expected status of health issues at certain points in time, after treatment is complete. Functional outcomes (b) describe the person's ability to function in relation to the desired usual activities. Quality-of-life outcomes (c) focus on key factors that affect someone's ability to enjoy life and achieve personal goals. Affective outcomes (d) describe changes in patient values, beliefs, and attitudes.

. **b.** The outcomes in (a) and (c) make the error of expressing the patient goal as a nursing intervention. Incorrect: "Offer the patient 60 mL fluid every 2 hours while awake." Correct: "The patient will drink 60 mL fluid every 2 hours while awake, beginning 1/3/25." The outcome in (d) makes the error of using verbs that are not observable and measurable. Verbs to be avoided when writing outcomes include "know," "understand," "learn," and "become aware."

. **b.** The terms goal, objective, and outcome are often used interchangeably to refer to the expected conclusion to the patient's health problem or expectation. Nurses use the phrase expected outcomes to refer to the more specific, observable, and measurable changes. Options a, c, and d are stated as interventions, rather than outcomes.

. **c.** A concept map care plan is a diagram synthesizing patient problems and interventions. The nurse's ideas about patient problems and treatments are the "concepts" that are diagrammed. These maps are used to organize patient data, analyze relationships in the data, and provide a holistic view of the patient's situation. Answers (a) and (b) are incomplete because the concepts being diagrammed may include protocols and standardized treatment guidelines but the patient problems are also diagrammed concepts. Clinical pathways are tools used in case management to communicate the standardized, interdisciplinary care plan for patients.

. **b.** A nurse-initiated intervention is related to the nursing diagnosis and projected outcome. It is an autonomous action based on scientific rationale. The physician or health care provider uses a physician-initiated interventions or order in response to the medical diagnosis: nurses execute these interventions safely and effectively. Collaborative interventions are initiated by other providers including pharmacists, respiratory therapists, or physician assistants.

Implementing

Antoinette Browne

Antoinette, a toddler, is brought to the well-child community clinic by her grandmother. The health history reveals recurrent nausea, vomiting, and diarrhea. Her physical examination reveals a negligible gain in height and weight, lethargy, and a delay in achieving developmental milestones.

Estelle Morrissey

Estelle is an 86-year-old woman who is in a long-term care facility because of multiple chronic health problems. She is alert and oriented to person, place, and time. She states, “I’m all alone. There’s no one left and I want to die. Can you help me?”

James McMahon

James, a 62-year-old man, is admitted to the intensive care unit in hepatic failure. He is critically ill, being monitored continuously, and receiving intravenous fluids and medications via central and peripheral IV catheters.

Learning Outcomes

After completing this chapter, you will be able to accomplish the following:

. List examples of how nursing interventions and nursing outcomes classifications can be used to implement care.
. Use cognitive, interpersonal, technical, ethical/legal, and QSEN competencies to implement a plan of nursing care.
. Use the eight implementation guidelines provided in the chapter.
. Describe six variables that influence the way a plan of care is implemented.
. Use ongoing data collection to determine how to safely and effectively implement a plan of care.
. Explain why reassessment after nursing intervention is important.
. Discuss what to do if a patient does not cooperate with the plan of care.
. Describe the risks and responsibilities of delegating nursing interventions.

evidence-based practice
implementing
indirect care intervention
nursing intervention
protocols
scope of practice
standing orders

During the **implementing** phase of the nursing process, the evidence-based nursing actions planned in the previous step are carried out. The purpose of implementation is to help the patient achieve valued health outcomes: promote health, prevent disease and illness, restore health, and facilitate coping with altered functioning. The plan of care is best implemented when patients who are able and willing to participate have maximum opportunities to engage in self-care. Family members and other support people, as well as other health care professionals, may also be involved in successfully implementing the plan of care (Table 18-1 on page 477). During the implementation phase, the nurse continues to collect data and to modify the plan of care as needed (Fig. 18-1 on page 478). All activities are documented in the format used by the nurse's institution or facility. For an example of implementation, see the accompanying Reflective Practice box on page 476.

UNIQUE FOCUS OF NURSING IMPLEMENTATION

In all nurse–patient interactions, the nurse is concerned with the patient's response to health and illness and the patient's ability to meet basic human needs. Whereas other health care professionals focus on selected aspects of the patient's treatment regimen, nurses are concerned with how the patient is responding to the plan of care in general. Be sure to review the competencies in Standard 5. Implementation in the American Nurses Association's (ANA's) *Nursing: Scope and Standards of Practice* (2021).

Nursing's Scope of Practice

Scope of practice describes the services that a qualified health professional is deemed competent to perform and permitted to undertake—in keeping with the terms of their professional license. The ANA states that the *Nursing: Scope*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

and Standards of Practice describes the "who," "what," "where," "when," "why," and "how" of nursing practice:

- **Who:** Registered Nurses (RN) and Advanced Practice Registered Nurses (APRN) comprise the "who" constituency and have been educated, titled, and maintain active licensure to practice nursing.
- **What:** Nursing is the protection, promotion, and optimization of health and abilities; prevention of illness and injury; facilitation of healing; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, groups, communities, and populations.
- **Where:** Where there is a patient in need of care.
- **When:** Whenever there is a need for nursing knowledge, compassion, and expertise.
- **Why:** The profession exists to achieve the most positive patient outcome in keeping with nursing's social contract and obligation to society (www.nursingworld.org/practice-policy/scope of practice/).

See Figure 17-2 in the preceding chapter (p. 453), which illustrates clinical decision making and scope of practice. The greater familiarity nurses have with their scope of practice, the better able they are to practice thoughtful, person-centered nursing. Benner (1984) classifies the ways nurses intervene with their patients as the domains of nursing practice:

- Helping role
- Teaching–coaching function
- Diagnostic and patient-monitoring function
- Effective management of rapidly changing situations
- Administering and monitoring therapeutic interventions and regimens
- Monitoring and ensuring the quality of health care practices
- Organizational and work-role competencies

The Nursing Interventions Taxonomy Structure

In 1992, McCloskey, Dochterman, and Bulechek published *Nursing Interventions Classification (NIC),* a report of research to construct a taxonomy of nursing interventions. New editions appeared in 1996, 2000, 2004, 2008, and 2013. Each of the interventions listed has a label, a definition, a set of activities that a nurse performs to carry out the intervention, and a short list of background readings. Advantages of having a standard classification of nursing interventions are discussed in Chapter 17.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO TECHNICAL SKILLS

James McMahon, a 62-year-old man, is admitted to the intensive care unit (ICU) in hepatic failure. He is critically ill, being monitored continuously, and receiving intravenous (IV) fluids and medications via central and peripheral IV catheters. During a recent clinical rotation in the ICU, I followed an extremely busy nurse who was caring for Mr. McMahon. He had several IV infusion lines and required numerous technologic devices for monitoring and care. The nurse asked me to hang a new bag of IV medication. I found myself completely overwhelmed and confused by the myriad tangle of IV lines and knew that I wouldn't be able to determine how to run the medication without the guidance of the nurse. I became frustrated because I should have been able to perform this task quickly and correctly if I had been working independently. I didn't want to risk hanging the IV medication and infusing it into a line with another fluid that was possibly incompatible. Nor did I want to risk running the medication through the incorrect port. The nurse was extremely busy, and I felt pressured to perform this task immediately.

Thinking Outside the Box: Possible Courses of Action

- Request that the nurse hang the medication once she was through with her other tasks.
- Hang the medication, hoping that it was compatible with the other fluids that were already infusing.
- Ask another nurse on the unit to hang the medication.
- Wait until the nurse was through with what she had to do, admit to her that I felt uncomfortable hanging the medication on my own, and then ask that she walk me through the process.

Evaluating a Successful Outcome: How Do I Define Success?

- The patient remains free from harm while receiving the necessary medication.
- The nurse recognizes the need to provide me with more guidance.
- I feel comfortable and competent in my skills.
- The patient receives efficient, safe care.

Personal Learning: Here's to the Future!

Luckily, there was a positive ending to this situation. I explained to the nurse that I was confused by the maze of IV lines and that I was uncomfortable administering the IV medication on my own. The nurse immediately recognized that the patient's lines were tangled and disorganized and some were unlabeled. With me at her side, she took the time to reorganize and label all of the lines, making it easier to visualize all of the medications and fluids the patient was receiving. We referenced a drug book to ensure that the medication was compatible with the other fluids that were running. She also walked me through the process of hanging the medication and connecting it to the appropriate port. The nurse appreciated the fact that I waited to ask her for help. As a result, the patient remained safe from injury. In addition, the nurse realized that she shouldn't have asked me to perform this task independently. I benefited from the experience because I became more familiar with this particular skill. As of now, I still find myself feeling somewhat anxious and uncomfortable with certain technical skills. However, I am finding that with each new clinical experience, I become more comfortable and more independent in my practice.

Colleen Kilcullen, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your competencies for professional practice? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Mr. McMahon? What factors might have influenced the nurse in assigning this task to the student? Did the nurse effectively delegate this intervention? Why or why not? Did the student adhere to ethical and legal guidelines with the response? If so, explain how. If not, what issues were present?

Patient-Centered Care: How can you keep your focus on providing respectful and compassionate care for Mr. McMahon—even when feeling overwhelmed?

Teamwork and Collaboration/Quality Improvement: What communication and interpersonal skills do you need to be able to approach other nurses and team members when you need help? What does quality care for Mr. McMahon "look like?" What did the experienced nurse teach the student by taking the time to label the lines and medications?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for administering Mr. McMahon's medications? What safety needs does he have and how can you meet them? What have you learned about the dangers of "busyness"?

Informatics: Can you identify the essential information that must be available in Mr. McMahon's drug record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Table 18-1 **Professional Nursing Relationships: Role Responsibilities and Related Competencies**

RELATIONSHIP	ROLE RESPONSIBILITIES	RELATED COMPETENCIES
Nurse–patient	• Communicate to patients that someone is concerned about them (as well as the disease) and is interested in how change in health state will affect their overall well-being. • Create an environment in which patients can commit their energies to health promotion or restoration or peaceful dying, confident that basic human needs are being addressed. • Challenge patients to develop self-	• Repertoire of therapeutic interpersonal behaviors: attending, listening, interviewing, nonverbal communication, touching, facilitating, coaching • Ability to establish trusting nurse–patient–family relationships • Demonstrated competence in the nursing roles of caregiver, teacher, counselor, advocate

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	care abilities that promote holistic health.	
Nurse–patient–family	• Develop in the patient and family the knowledge, attitude, and skills that will enable them to respond to the self-care challenges of their health or illness state. • Intervene as appropriate to promote healthy family functioning. • Educate the family to be wise and assertive health care consumers.	
Nurse–nurse	• Support one another's efforts to deliver quality nursing care; work collaboratively with nursing administration to improve quality care. • Provide creative leadership—formally or informally—to make the nursing unit a satisfying and challenging place to work. • Supervise the nursing care given by other nursing personnel; affirm the nursing strengths of others, and constructively address the nursing deficiencies encountered. • Enhance the professional development of self and other nurses through active participation in professional organizations.	• Communication • Teaching/counseling/advocacy • Assertiveness • Collaboration • Coordination • Group process • Organization • Leadership • Delegation • Change strategies • Problem solving • Decision making • Conflict resolution
Nurse–health care team	• Communicate clearly nursing's perspective regarding the patient and family to the health care team. • Coordinate the inputs of the multidisciplinary team into a comprehensive care plan. • Serve as a liaison between the patient and family and the health care team, as necessary.	

The researchers involved in the development of NICs are also committed to developing a classification of patient outcomes for nursing interventions, called Nursing Outcomes Classifications (NOCs). This research aims to:

. Identify, label, validate, and classify nursing-sensitive patient outcomes and indicators
. Evaluate the validity and usefulness of the classification in clinical field testing
. Define and test measurement procedures for the outcomes and indicators

This research continues in an effort to develop a common nursing language to optimize the design and delivery of safe, high-quality, and cost-effective care.

Care Coordination, Continuity, and the Nurse

One of nursing's major contributions to the interprofessional health care team is the role of coordinator (discussed in Chapter 12). Care can easily become fragmented when patients are seen by numerous specialists—each interested in a different aspect of the patient—and in different settings. At best, patients express feeling that no one single person really knows them and can talk with them about what is going on and how it all may affect them in the future. At worst, the orders of different specialists may conflict with one another and be counterproductive. Therefore, it is important for you as the nurse to make rounds with other health care professionals and to read the results of consultations that patients have had with specialists. You can then interpret the specialists' findings for patients and family members, prepare

patients to participate maximally in the care plan in both institutional and community settings, and serve as a liaison among the members of the health care team. Nurse case managers and navigators are specialists in the role of care coordinator and work in both inpatient and community settings.

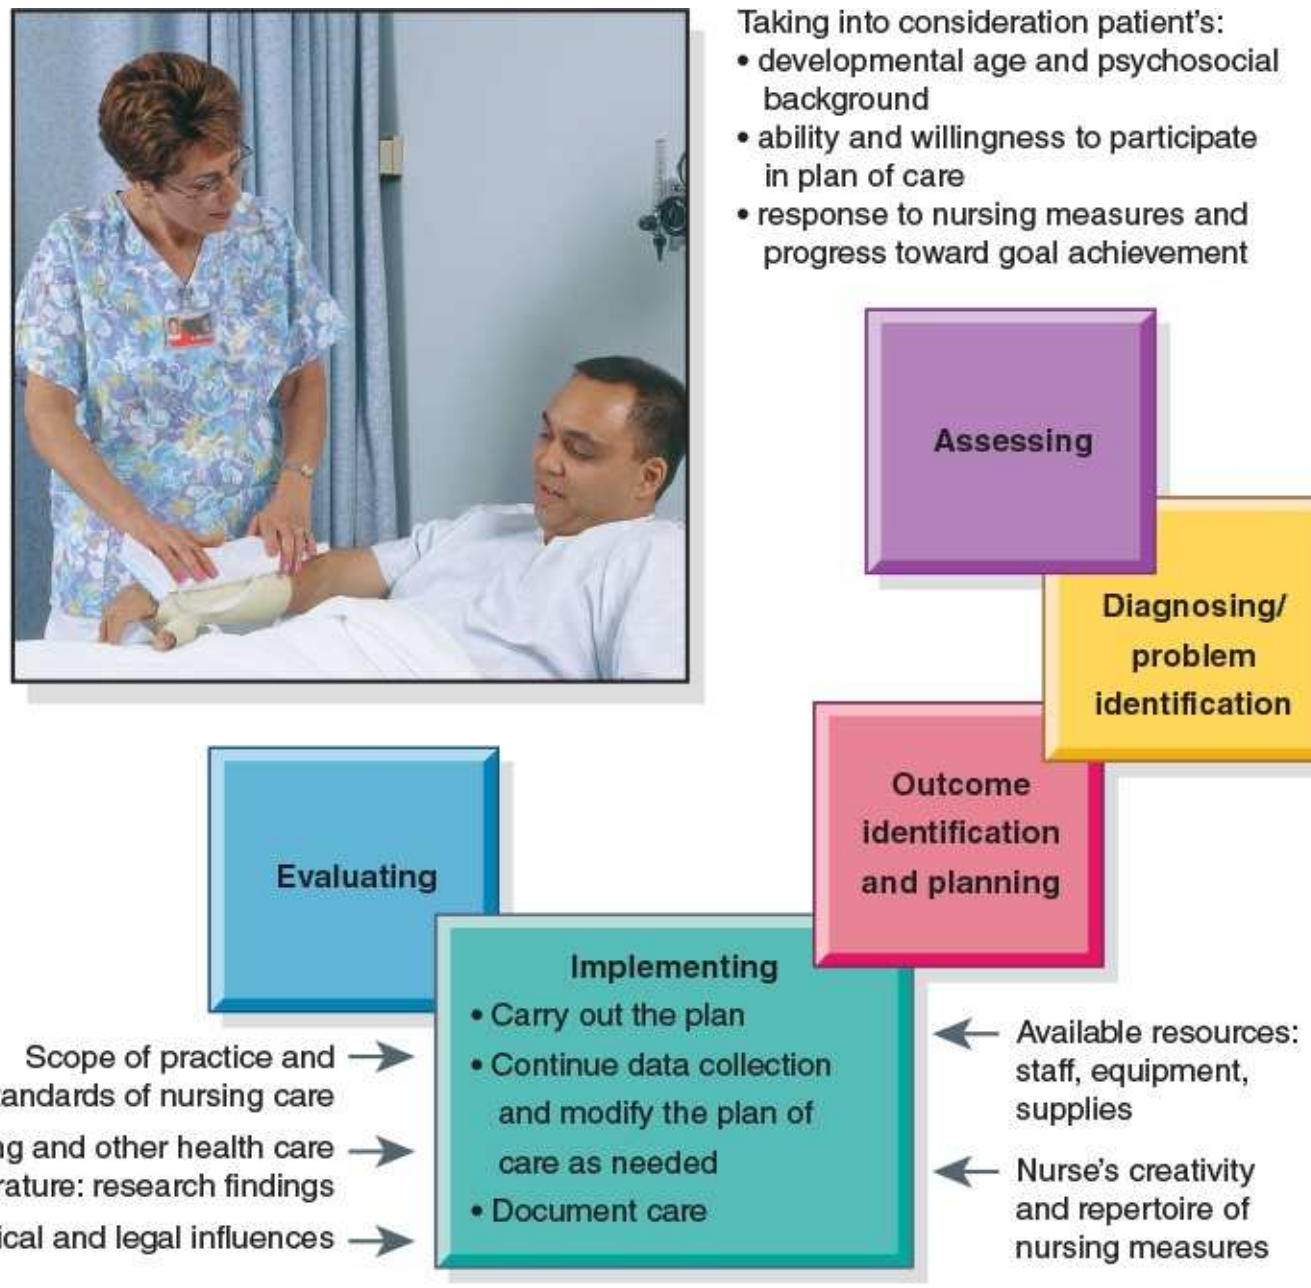

FIGURE 18-1. Implementing involves carrying out the plan of care, which is modified in response to patient changes. Numerous variables influence the way the care plan is implemented (see *arrows*). (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

Think back to **Antoinette Browne**, the toddler described at the beginning of the chapter. As a result of the child's delays, multiple disciplines would likely be involved in caring for her. The nurse would play a major role as coordinator for the child's care, ensuring communication among all team members. In addition, the nurse would act as the liaison between the other members of the team to ensure that the child's grandmother understands the care plan.

CRITICAL THINKING/CLINICAL REASONING AND JUDGMENT, AND IMPLEMENTING

As you implement the plan of care, you are constantly engaging in clinical reasoning and judgment about what you are doing. Since patient conditions can change dramatically in minutes, you must reassess the patient for changes in status that may dictate a different set of interventions. You also want to be sure that research supports the interventions you have selected and be open to better ways of addressing patient problems and issues. **Clinical inquiry** is defined as the ongoing process of questioning and evaluating practice and advancing informed practice (Mick, 2017, p. 39). In every clinical setting, we should hear nurses and other members of the team actively questioning whether there are better ways to achieve desired patient outcomes. "Am I offering everything that is currently available to achieve the best outcome?" Finally, you are always monitoring the patient's responses to your interventions so that you can modify the care plan if

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

needed. Remember Alfaro's rule (Alfaro-LeFevre, 2014, p. 161):

Assess, reassess, revise, record:

- *Assess* patients before performing nursing actions.
- *Reassess* them to determine their responses after you perform nursing actions.
- *Revise y*our approach as indicated.
- *Record* patient responses and any changes you made in the care plan.

As a student, you should always ask if you are competent to implement the plan of care. If you doubt that your cognitive, interpersonal, or technical competencies are adequate to successfully implement the care plan, it is your responsibility to ask for help. Getting help when you need it demonstrates your primary commitment to the patient. Expert nurses understand that learning is a lifelong practice and that we need one another to continue to master clinical skills.

IMPLEMENTING AND INTERPERSONAL COMPETENCE

Nursing is rarely a solo activity. Nurses are always working with patients, families, communities, and other nurses and health care professionals (see Table 18-1 on page 477). While nurses need knowledge of best practice interventions and technical skills to implement the care plan, it is also true that the nurse's interpersonal competence to a large degree determines how successfully the plan is implemented. If your patients and team do not trust you, it will be difficult to motivate everyone's best effort toward achieving goals. Alfaro-LeFevre (2014, p. 161) writes that "your ability to communicate (listen, speak, and write effectively) with patients, families, assistive personnel (APs), and other professionals makes the difference between competent, efficient care and care that is sloppy, unprofessional, and prone to errors." You may want to talk with patients about what qualities and attributes they value in a nurse. You are sure to discover that your respect, empathy, compassion, accountability, and trustworthiness are highly valued.

Remember **Estelle Morrissey** telling her nurse, "I'm all alone. There's no one left and I want to die. Can you help me?" A skilled nurse would try to find out what Estelle really wants. Is she simply lonely and longing for companionship, or is this an authentic request for assistance in suicide if this is a legal option in your state? The nurse who responds to Ms. Morrissey might document the following intervention.

> Found Ms. Morrissey alone in her room when the other residents were in the dining room. She told me, "There's no one left and I want to die. Can you help me?" I sat down beside her and asked her what she really wants and she replied that she misses her husband (who died 5 years ago) and her friends from church. I asked her if she wanted me to see if anyone from her church would be able to visit and she visibly brightened. Upon leaving her room, I called her minister to arrange a visit, and we hope to set up a visitation schedule.
>
> 9/22/25, 1000, Carol Taylor, RN

This example demonstrates the importance of documenting what you do so that anyone else hearing Ms. Morrissey's concerns would know what is planned and be able to evaluate its effectiveness.

One tip for practice is to cultivate the habit of reflecting on your clinical encounters each day. As you walk out of a human encounter, mentally look back at what you are leaving in your "wake." Were you one more anonymous person who did something "to" the patient? Were you toxic? Or were you the one who will be remembered as making or being the critical difference for the patient? The choice is yours in every encounter. At the end of your shift, ask, "Are my patients better for having had me today?" "Is my team better for my being in it today?"

TYPES OF NURSING INTERVENTIONS

Nursing Interventions Classification

The NIC project defines a **nursing intervention** as "any treatment based upon clinical judgment and knowledge that a nurse performs to enhance patient/client outcomes" (Bulechek et al., 2008, p. xxi). The NIC project goes on to describe

types of interventions:

> Nursing interventions include both direct and indirect care; those aimed at individuals, families and community; and those for nurse-initiated and other provider-initiated treatments.

A **direct care intervention** is a treatment performed through interaction with the patient(s). Direct care interventions include both physiologic and psychosocial nursing actions and include both the "laying on of hands" actions and those that are more supportive and counseling in nature.

An **indirect care intervention** is a treatment performed away from the patient but on behalf of a patient or group of patients. Indirect care interventions include nursing actions aimed at management of the patient care environment and interdisciplinary collaboration. These actions support the effectiveness of direct care interventions.

A community (or public health) intervention is targeted to promote and preserve the health of populations. Community interventions emphasize the health promotion, health maintenance, and disease prevention of populations and include strategies to address the social and political climate in which the population resides.

Independent and Collaborative Interventions

When you carry out the interventions identified in the care plan, you are implementing the care plan. When implementing the care plan, you function independently and collaboratively. See Chapter 17 for descriptions of nurse-initiated, health care provider–initiated, and collaborative interventions.

The three types of nursing interventions can be illustrated by the example of **Antoinette Browne**, the toddler with gastrointestinal symptoms and delayed growth and development. If the health care provider orders a series of gastrointestinal studies, it is the nurse's responsibility to prepare the patient by executing the health care provider's order for cleansing the bowel. This nursing action is a health care provider–initiated intervention. When the nurse senses that the grandmother seems unusually fearful of the outcome of the studies, and explores the grandmother's fears and then follows up with appropriate teaching and counseling, the nurse is using nurse-initiated interventions. When a multidisciplinary team conference is held to discuss the patient's failure to progress, the nurse works collaboratively with the psychiatrist, gastroenterologist, social worker, and child development specialist to develop a comprehensive care plan; this involves collaborative nursing interventions.

Carpenito-Moyet (2017, pp. 37–38) describes how the major focus of intervention differs according to the type of nursing diagnoses or problem being addressed.

For actual nursing diagnoses/problems, interventions seek to:

- Reduce or eliminate contributing factors of the diagnosis or problem
- Promote higher-level wellness
- Monitor and evaluate status

For risk nursing diagnoses/problems, interventions seek to:

- Reduce or eliminate risk factors
- Prevent the problem
- Monitor and evaluate status

For possible nursing diagnoses/problems, interventions seek to:

- Collect additional data to rule out or confirm the diagnosis

For collaborative problems, interventions seek to:

- Monitor for changes in status
- Manage changes in status with nurse-prescribed and health care provider–prescribed interventions
- Evaluate response

Protocols and Standing Orders

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Protocols and standing orders expand the scope of nursing practice in certain clearly defined situations. **Protocols** are written plans that detail the nursing activities to be executed in specific situations. Although some protocols specify routine aspects of nursing care (e.g., protocols that describe nursing responsibilities when a patient is admitted to or discharged from the institution), other protocols include **standing orders** that empower the nurse to initiate actions that ordinarily require the order or supervision of a health care provider. Examples include admission protocols for obstetrics and gynecology patients, protocols for bowel programs that allow the nurse to select and administer necessary bowel interventions, standard orders for narcotic overdoses that specify the agents the nurse is to administer to reverse respiratory depression in an emergency, and standard orders for pain management that enable the nurse to select the strength of the medication to be given within preset ranges.

Care Bundles

The Institute for Health Improvement (IHI) defines **care bundle** as a structured way of improving processes of care and patient outcomes: A small straightforward set of evidence-based practices—generally three to five—that, when performed collectively and reliably, have been proven to improve patient outcomes. The power of a bundle "comes from the body of science behind it and the method of execution, with complete consistency … A bundle ties the practices together into a package of interventions that people know must be followed for every patient, every single time" (http://www.ihi.org/resources/Pages/ImprovementStories/WhatIsaBundle.aspx).

The IHI website has examples of care bundles that have dramatically improved patient outcomes including the central line bundle and ventilator bundle.

IMPLEMENTING THE PLAN OF CARE

When carrying out the plan of care, nurses use specialized abilities to (1) determine the patient's new or continuing need for nursing assistance, (2) promote self-care, and (3) assist the patient to achieve valued health outcomes. Nurses must also organize necessary resources and anticipate unexpected outcomes and situations. Novice nurses need to be sure they possess the nursing competencies necessary to carry out the plan of care, and to consult with their instructor or preceptor if unsure of their knowledge or ability.

Reassessing the Patient and Reviewing the Plan of Care

As you begin your professional practice, you will be expected at any time to provide a rationale for your actions. Does research demonstrate that this is the best intervention to achieve a desired outcome? The student care plans at the end of many clinical chapters provide a rationale for each intervention, and it may be helpful to check out some of these care plans now.

A patient's condition can change dramatically in a matter of minutes. Therefore, it is critical to assess the patient carefully before initiating any nursing intervention to make sure that the care plan is still responsive to the patient's needs and prioritized to the most pressing of those needs.

Each nurse implementing the plan should:

- Be sure that each nursing intervention is supported by a sound scientific rationale, as demanded by **evidence-based practice** (see Chapter 2)
- Be sure that each nursing intervention is consistent with your scope of practice and professional standards of care and consistent with the protocols, policies, and procedures of the institution or facility
- Be sure that the nursing actions are safe for this particular patient and individualized to their preferences
- Clarify any questionable orders

Using Patient Boards or Dry-Erase Boards

Increasingly, a variety of practice sites are using dry erase dry-erase boards as a convenient two-way communication system between patients and their professional caregivers. They allow nurses to communicate with the patient and the patient's family and to let patients know that their voices are being heard. They are an excellent way to involve patients in their care plan and have been shown to increase patient satisfaction. They typically include the patient's priority goals and comfort/pain scales as well as reminders to providers to wash their hands and reminders to patients to "Please call don't fall."

The content on these boards will change according to the unit and its priorities. Figures 18-2 and 18-3 illustrate patient dry-erase boards for a hospital inpatient adult unit and a pediatric emergency room.

FIGURE 18-2. Adult inpatient dry-erase board. (*Source:* Used with permission, VisiCare™ 2017. For Information/inquires click http://www.VisiCare.com. VisiCare™ is a DBA of Insignia Marketing, Inc. Patent pending. 281-465-0040 Info@VisiCare.com.)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 18-3. Pediatric emergency room dry-erase board. (*Source:* Used with permission, VisiCare™ 2017. For Information/inquires click http://www.VisiCare.com. VisiCare™ is a DBA of Insignia Marketing, Inc. Patent pending. 281-465-0040 Info@VisiCare.com.)

Make sure you learn about how dry-erase boards are being used on your clinical units, what information you can expect to find there, and what your responsibilities are to update content. These boards become meaningless if not updated frequently in response to patient changes.

Clarifying Prerequisite Nursing Competencies

To implement the plan of nursing care, nurses need blended intellectual, interpersonal, technical, and ethical/legal competencies as well as mastery of the Quality and Safety Education for Nurses (QSEN) Competencies that are described in Chapter 13 and illustrated in the Reflective Practice displays that introduce each chapter. Each nurse has a unique blend of these competencies and can act effectively to the extent that their abilities match the patient's need for nursing care.

Remember **James McMahon**, the critically ill patient in the ICU. Although technologic skills are key in this area, the nurse also needs to implement care that integrates intellectual, interpersonal, and ethical and legal competencies because of the patient's complex needs. QSEN competencies—patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics—also promote a good outcome.

Always notify your nursing instructor or nurse mentor if you believe that you lack any competencies needed to safely implement the care plan.

QSEN SAFETY

Nurses committed to safety and minimizing the risk of harm to patients and providers will examine human factors and other basic safety design principles as well as commonly used unsafe practices such as work-arounds and dangerous abbreviations. These nurses value their own role in preventing errors.

Planning Ahead and Organizing Resources

In today's hectic health care environments, successful implementation of the plan of care requires a high degree of organization and efficiency.

Patient and Patient Visitors

Make sure that the patient is physically and psychologically prepared for what you are going to do. Give the nursing intervention the best chance for success by ensuring that the patient is not in too much pain to cooperate, understands what is being attempted and why they should cooperate, and is not distracted (e.g., by wanting to talk with visitors or watch TV). If visitors are in the room, check with the patient to see if they want the visitors to stay during the procedure. If a family caregiver needs to learn new caregiving skills, try to schedule your interventions at a time appropriate for the patient and convenient for the family caregiver.

Equipment

Anticipate all the equipment you will need to successfully carry out the intervention, and arrange it so that it is easily accessible. Be sure to order sufficient supplies at the beginning of the shift for the care you expect to provide, and be thoughtful of the nurse who will follow you by leaving adequate supplies. Follow facility policy when ordering supplies to ensure proper charges.

Nurse Self Care Alert

To avoid injury on the job, take the time to use proper assistive devices, such as lifts for heavy patients or transfer boards for patients with limited mobility.

Environment

Think through the proper environment for each intervention. Thoughtful, person-centered practice means paying special attention to respecting the patient's dignity, privacy, and safety needs. Remember routine measures as simple as closing a door or pulling drapes. These considerations are of special importance when patients or residents share rooms. For example, administering an enema can be embarrassing for the patient and unpleasant for the patient's roommate. With some planning, the intervention can be scheduled in a private bathroom or at a time when the roommate is absent.

Personnel

Identify whether you can carry out the planned intervention alone or if you need assistance. To avoid injury to both patients and professional caregivers, be sure that interventions are attempted by the right person or by a sufficient number of people. Because it is easy to underestimate the strength it takes to lift or support a large patient, it is always safer to err on the side of having too much help rather than not enough. Teams of student nurses can begin each rotation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

by asking, "Who thinks they might need help today?" The team can then plan to coordinate care so that help is available when needed.

Time Management

One of the most essential skills you will develop in your clinical experiences is time management. Almost any experienced nurse will tell you that in today's health care environments where efficiency reigns, prioritizing face time with patients is an everyday challenge. Too often, the demand to utilize the electronic medical record to chart every bit of assessment data and intervention further limits time spent with patients. Remember that Benner includes both the nurse's helping role and organizational and work-role competencies in the domains of nursing. Be sure as you plan care for the patients in your caseload that you anticipate the time needed for the interventions you intend to carry out and prioritize these from most to least important.

Anticipating Unexpected Outcomes and Situations

When you learn about new nursing procedures and interventions, you often see a list of possible adverse effects. An **adverse reaction** is an unwanted or harmful reaction experienced following the administration of a drug, diagnostic test, or therapeutic intervention under normal conditions of use.

Although everyone hopes never to encounter these complications, they do occur with some frequency. The skilled nurse knows what might happen if an intervention "goes wrong" and is prepared to deal with the new challenge. This may be as simple as accurately assessing how much support a patient may need to avoid a fall when ambulating for the first time after surgery or being prepared to respond to complaints of burning at a new intravenous (IV) site. For further consideration of unexpected outcomes and situations, refer to *Taylor's Clinical Nursing Skills* by Pamela Lynn and *Taylor's Video Guide to Clinical Nursing Skills* by Wolters Kluwer.

Unfolding Patient Stories: Mona Hernandez • Part 1

Mona Hernandez, a 72-year-old female admitted to an acute care unit with pneumonia, is receiving oxygen via nasal cannula and intravenous fluids. An activity order is written for "out of bed to chair and ambulate three times a day." How would the nurse plan activity for Mona? What unexpected outcomes should the nurse anticipate when getting her out of bed for the first time? What steps can the nurse take to ensure patient safety with activity? (Mona Hernandez's story continues in Chapter 30.)

Care for Mona and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

Ensuring Quality and Patient Safety: Preventing Errors and Omissions

Keeping patients safe and delivering high-quality care require a vigilance today that was unknown as recently as 10 years ago. Anytime you feel tempted not to wash your hands or clean them with gel or foam before a patient encounter, ask yourself if you are willing to complicate your patient's recovery by introducing infection, increasing the length of stay and related costs. Every nurse should be familiar with the easily accessible resources available at the following websites and web pages:

- Agency for Healthcare Research and Quality (AHRQ), Quality and Patient Safety website: https://www.ahrq.gov/professionals/quality-patient-safety/index.html
- The Institute for Health Care Improvement's Patient Safety web page: http://www.ihi.org/Topics/PatientSafety/Pages/default.aspx
- The Joint Commission's Patient Safety web page: https://www.jointcommission.org/topics/patient_safety.aspx

Alfaro-LeFevre (2014) counsels nurses to keep patients safe during implementation by preventing errors and omissions and building safety nets (Fig. 18-4). Starting with your first clinical experience, develop the habit of monitoring closely for error-prone situations. The goal is to "catch" possible errors and omissions early. Remember that anyone can make a mistake and everyone, including the most senior health care provider or nurse, needs surveillance.

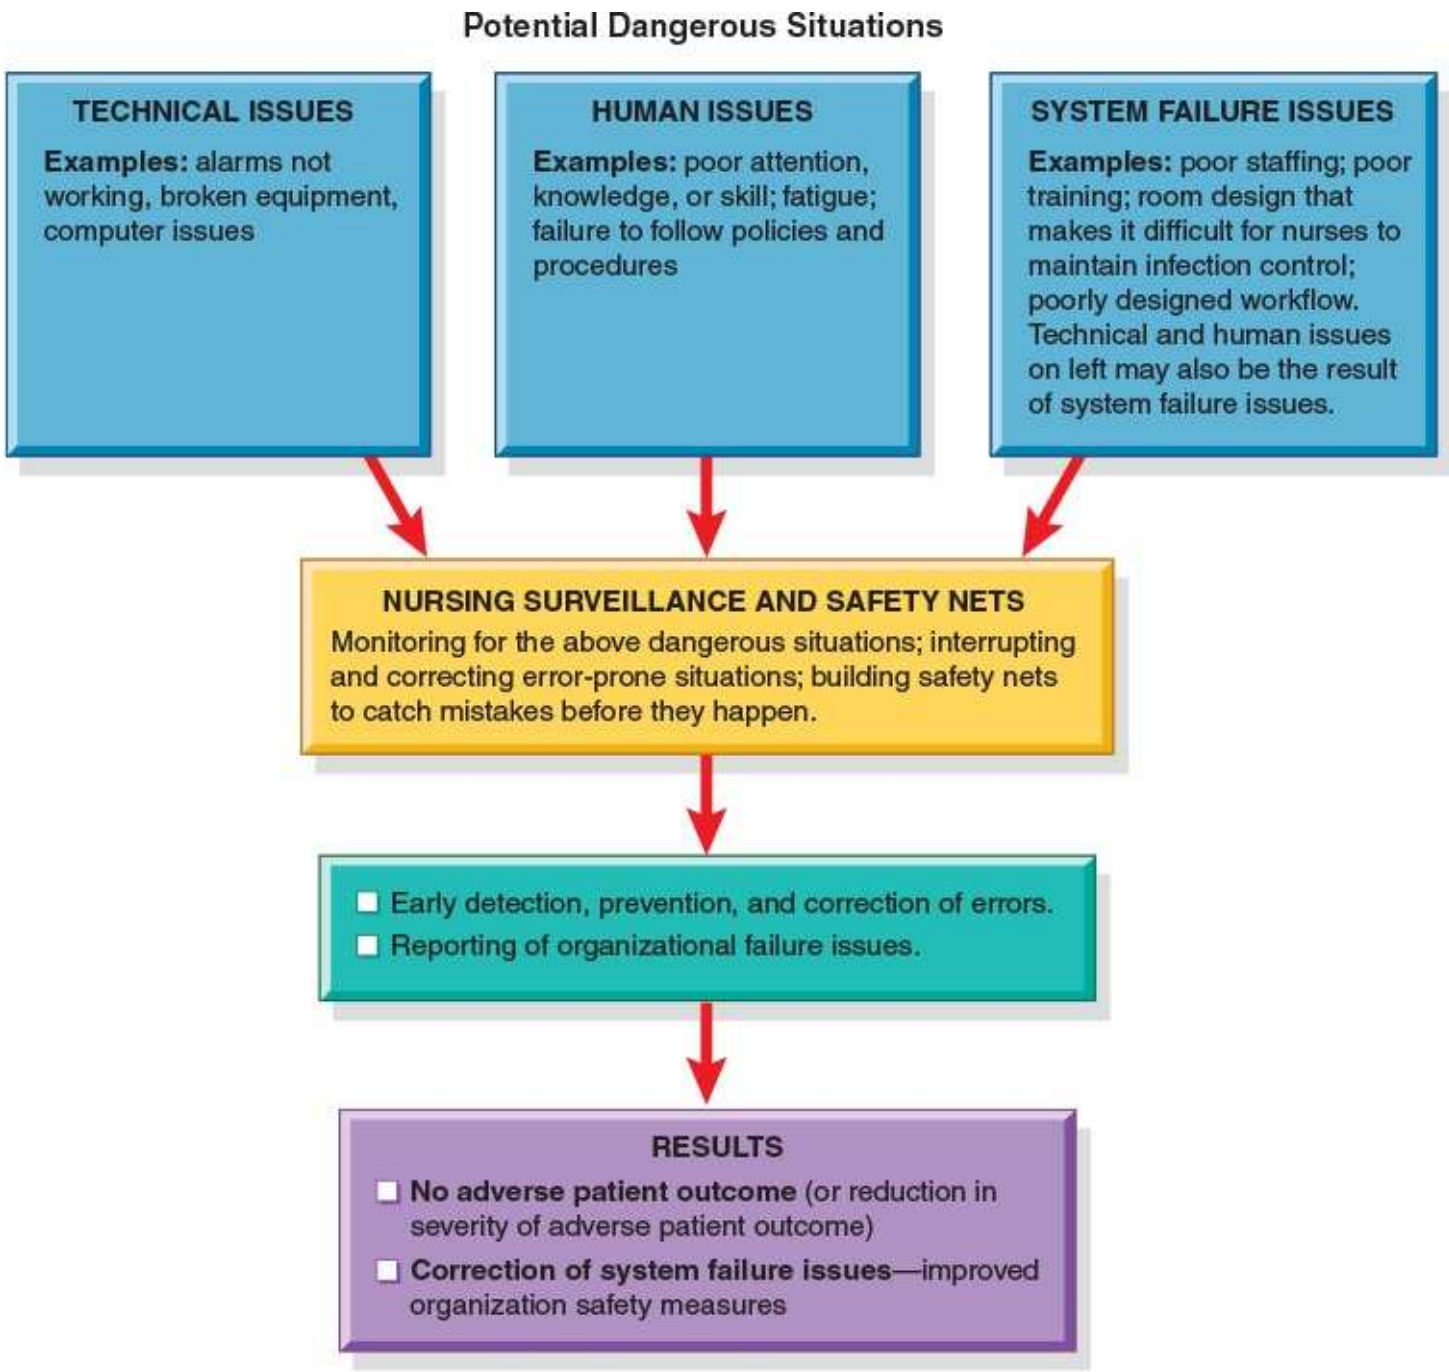

FIGURE 18-4. How monitoring for dangerous situations promotes early correction of problems and keeps patients safe. (© 2010 www.AlfaroTeachSmart.com. Used with permission.)

Nursing Advocacy in Action

Patient Scenario

The emergency department (ED) is very rushed and overcrowded. Mrs. Penuela, who speaks little English, grabs you when you walk into the waiting area and begs someone to look at her husband, who is holding his head and moaning. When you finally get him in the unit to be assessed, he has a blood pressure of 240/150 mm Hg. He speaks a little more English than his wife, but is not fluent. However, you are able to learn that he stopped taking his blood pressure medication because he couldn't afford the prescription. He also lost his job and the family lost their house because of an inability to make mortgage payments. They are now living with her brother. Mr. Penuela is in the ED for several hours while intravenous medications are administered. You are shocked to discover that the only discharge orders for Mr. Penuela are a prescription for the same medication he was on previously, which he couldn't afford. His doctor tells you that the ED isn't a charity or social service—"our job is to fix medical problems."

Implications for Nursing Advocacy

How will you respond if you are Mr. Penuela's nurse? Talk with your classmates and experienced nurses about the questions that follow.

- If you elect to advocate for the Penuelas, what practical steps can you take to ensure better health outcomes?
- What is it reasonable to expect of a student nurse, a graduate nurse, and an experienced nurse in this situation?
- What advocacy skills are needed to effectively respond to this challenge?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Remember **James McMahon**, the critically ill patient in the ICU. When the nurses caring for Mr. McMahon spent times relabeling and organizing his lines they were preventing a possible error.

Henneman et al. (2010) recommend the following strategies to identify, interrupt, and correct errors:

- *Error identification strategies:* knowing the patient, knowing the "players," knowing the plan of care, surveillance, knowing policy and procedure, double-checking, using systematic processes, and questioning.
- *Error interruption strategies:* offering help, clarifying, and verbally interrupting.
- *Error correction strategies:* persevering, being physically present, reviewing or confirming the plan of care, offering options, referencing standards or experts, and involving another nurse or health care provider.

The Joint Commission encourages patients to become active, involved, and informed participants on the health care team. Figure 18-5 illustrates The Joint Commission's initiative to get patients to more actively participate in their care by speaking up. The website offers numerous videos and infographics in English and Spanish that you can use with your patients.

Promoting Self-Care: Teaching, Counseling, and Advocacy

Although most people can meet their basic human needs independently, illness and the stress of diagnostic and therapeutic measures may interfere with a person's usual practice of self-care. Nurses assess patients' abilities to meet their human needs independently. Nurses can fail patients by doing too much for them and by encouraging negative, sick-role behaviors, such as inappropriate dependence. Conversely, there is a time and a place for the "tender loving care" that says to a patient, "I know you may be able to do this for yourself, but just this once, how about if I do it, and we'll talk!" Balancing the need to encourage a patient's best self-care effort with the effort to make each patient feel cared for is an important component of the art of nursing.

If patients and their families want to participate actively in seeking wellness, preventing disease and illness, recovering health, and learning to cope with altered functioning, they need effective self-care behaviors. Nurses sensitive to the importance of patients learning to direct and manage their own care use nurse–patient interactions for both planned and spontaneous teaching, counseling, and advocacy. These nursing roles are described in Chapters 6 and 9. See also the accompanying Nursing Advocacy in Action box. Referring families to a community support group or other resources further enhances the self-care behaviors being developed. See Through the Eyes of a Family Caregiver (on page 487) for a description of one wife's experiences when her husband was discharged home.

Remember: the only way you can be sure that patients or family caregivers have mastered a skill is watching them perform it. Once you observe them doing a procedure correctly you can be confident that learning—as well as teaching—has occurred.

Assisting Patients to Meet Health Outcomes

In this phase of the implementation process, the nursing team carries out the nursing orders detailed in the nursing care plan. If the care plan is well constructed, carrying out its orders is the nurse's most important task and should receive top priority. The nursing actions planned to promote patient goal or outcome achievement and the resolution of health problems should be carefully executed. Implementation guidelines are listed in Box 18-1 on page 487.

Because understaffing is a problem in many practice settings, nurses must learn to use their time wisely and to maximize each patient encounter. Inserting an IV can be simply that, or it can be an opportunity to gather additional focused data, to communicate concern for what the patient is experiencing and offer support, and to teach and counsel as appropriate. How the nurse uses the time for inserting the IV determines how effective the nurse is in helping the patient to achieve the patient's goals and outcomes. See the accompanying Through the Eyes of a Student display (on page 488) for one student's account of an important bath.

The Joint Commission

SpeakUp™

Speak Up™ For Your Rights

As a patient, you have the right to ...

- Be informed about your care.
- Make decisions about your care.
- Refuse care.
- Know the names of your caregivers.
- Be treated with courtesy and respect.
- Be listened to by your caregivers.
- Have an interpreter.
- Receive information in a way that meets your needs, such as if you have impaired vision.
- Religious or spiritual services.
- Copies of your test results and medical records.
- Have a patient advocate with you during your care.
- Privacy of your health information.
- Ask that pictures or videos taken of you be used only to identify you or assist in your care.
- Care that is free from discrimination.

Be active in your care ...

- Ask questions.
- Pay attention to instructions from your caregivers.
- Inform caregivers about your medicines, supplements and allergies.
- Share your wishes about life-saving actions, such as being put on a ventilator.

Your advocate can help ...

- Get information and ask questions when you cannot.
- Ask for help if you are not getting the care you need.
- Make care decisions when you cannot (so long as he or she is a legal guardian, a health care power of attorney, or has some other legal permission).

If you think something is wrong ...

- Ask to speak to a patient representative.
- Work with the facility or health system to address the issue.
- File a complaint with the state agency that licenses or certifies the facility.
- Report a patient safety event to The Joint Commission.

The goal of Speak Up™ is to help patients and their advocates become active in their care.

Speak Up™ materials are intended for the public and have been put into a simplified (i.e., easy-to-read) format to reach a wider audience. They are not meant to be comprehensive statements of standards interpretation or other accreditation requirements, nor are they intended to represent evidence-based clinical practices or clinical practice guidelines. Thus, care should be exercised in using the content of Speak Up™ materials. Speak Up™ materials are available to all health care organizations; their use does not indicate that an organization is accredited by The Joint Commission.

Through the Eyes of a Family Caregiver

"The nurses never told me there'd be days like this."

I wasn't prepared for a roller coaster ride when my husband became ill. My husband was admitted to the hospital in an emergency condition, became confused when his electrolytes were off balance, went into cardiac arrest and had CPR, was placed on a ventilator, and was sedated because he was too apprehensive about the ventilator. I had reached the lowest point as I sat by his bedside for days, talking to him and wondering if he heard me.

My spirits soared the day they brought him out of his sleep state and he recognized me and was hungry for real food. The next day when I went to the hospital, I plummeted to the low point again when he was crumpled in bed like a confused rag doll with his hospital gown up to his chest and the sheet to his ankles. I started to cry, and the nurse came and put her arm around me. She said, "Don't think he's taken a turn for the worse. There will be good days and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

bad days as he recovers." No one had prepared me for that—and her arm around me and her words were so consoling.

When I brought him home after 6 weeks in the hospital, I was not prepared for his anger at being confined to the house (in a heat wave) and not being allowed to drive. His reasoning that he had to get a haircut because he hadn't had one in 2 months made sense to him. My saying that no one would care about the length of his hair did not soothe his anger.

He couldn't accept the fact that he was too weak to go up and down the steps more than once a day, so he insisted on going to the basement. Going down was simple; coming up wasn't. We forgot there was no railing (which he needed to haul himself up) on the last four steps. He solved the problem by sitting on the steps and lifting himself up a step at a time. Then he got to the floor at the top and couldn't stand up. I couldn't lift him. We were stuck. Again, I took a nose dive.

I thought I understood how difficult it would be for him to readjust. I knew he would be depressed and expected him to lean on me. But I was not prepared for his frustration to come out as anger at me. It would have been helpful to have someone prepare me. Or, it would be nice to have a nurse put her arm around me now when my roller coaster plummets.

—Eleanor Faven, Philadelphia, Pennsylvania

Box 18-1 Implementing Guidelines

- When implementing nursing care, remember to act in partnership with the patient/family.
- Before implementing any nursing action, reassess the patient to determine whether the action is still needed.
- Approach the patient competently. Know how to perform the nursing action, why the action is being performed, and potential adverse responses. Have all equipment and supplies ready.
- Approach the patient caringly. Explain the nursing action using language the patient understands. Communicate genuine concern for what the patient is experiencing.
- Modify nursing interventions according to the patient's (1) developmental and psychosocial background, (2) ability and willingness to participate in the care plan, and (3) responses to previous nursing measures and progress toward goal/outcome achievement.
- Check to make sure that the nursing interventions selected are consistent with your scope of practice and standards of care and within legal and ethical guides to practice.
- Always question that the nursing intervention selected is the best of all possible alternatives. Consult colleagues and the nursing and related literature to see if other approaches might be more successful. Evaluate the effectiveness of the intervention selected, noting any factors that positively or negatively influenced the outcome.
- Develop a repertoire of skilled nursing interventions. The more options one can choose from, the greater the likelihood of success.

When working with patients to achieve the outcomes specified in the care plan, remember that nothing about the care plan is fixed. Some of the most important variables that influence how the care plan is implemented follow.

Patient Variables

Ideally, the patient is primary in determining how nursing interventions are implemented. Successful nurses modify their nursing actions according to the patient's (1) changing ability and willingness to participate in the care plan and (2) previous responses to nursing interventions and progress toward achieving goals or outcomes. Other important variables are the patient's developmental stage, psychosocial background, and culture.

DEVELOPMENTAL STAGE

Addressing the developmental needs of a patient involves identifying the patient's developmental stage, as well as the developmental tasks related to this stage and their relationship to nursing care. However, be careful not to let stereotypes about developmental stages and tasks influence patient care. To implement a comprehensive and holistic care plan, nurses must find creative ways to meet developmental needs. This is of greatest importance when patients are separated from their families and home environments for long periods.

Through the Eyes of a Student

One of my first patients was a woman with a history of Alzheimer's disease. When I was assigned this patient, I knew that I was not going to have a good day. I had been introduced to her the week before, when I had orientation. She was sitting in a geriatric chair in the hallway, where she sang at the top of her lungs and threw tissues on the floor.

Occasionally, she would curse at a person passing by.

I took a deep breath and entered her room. At her bedside, I introduced myself. With a few choice words, she told me to get out of her room. I tried to ignore her response and prepared her breakfast tray. She proceeded to throw her scrambled eggs around the room. After I took the tray away from her and finished cleaning up the mess, it was time for preconference. At preconference, my instructor told me that we were going to "tub" my patient. I had visions of a grand fiasco in the tub room, and I dreaded giving her the bath.

My instructor and I took her to the tub room by wheelchair. Once we convinced her to get in the tub, she did nothing but yell that it was cold. We started the water and she yelled even louder. I knew everyone could hear her in the hallway as she cursed and yelled, but as the bath proceeded, she quieted down and stopped fighting me. We completed the bath and wheeled her back down the hall to her room. I bundled her up in blankets and put her in the Geri chair in the hallway. She was so relaxed from the bath that she let me brush her hair and put it in a ponytail. While I was brushing her hair, she fell asleep. I did my chart until her lunch arrived. When I set her up for her lunch and told her I would be leaving, she thanked me, and it made my day. All the struggling I went through all day with her and she thanked me. When I went home, I felt really good about helping her. During all my worrying about the day being a fiasco and the embarrassment of having a patient yell at me, I had lost sight of the patient herself and what she needed me to do for her. By her thanking me at the end of the day, I realized that when my clinical instructor forced me to do something for my patient that the regular staff of the hospital wouldn't do, I was meeting her basic needs, and my patient recognized that.

—Jeanene C. Smith

Think back to **Antoinette Browne**, the toddler with physical and developmental delays. The nurse would creatively adapt interventions to meet the needs of this toddler.

PSYCHOSOCIAL BACKGROUND AND CULTURE

When choosing nursing interventions, the nurse should consider and respect the patient's socioeconomic background and culture. Confronted with a malnourished patient on a limited income who rents a single room in a boarding home, a nurse cannot simply teach the importance of including more protein in the diet. To be effective, the nurse must explore the realistic issue of whether the patient can afford and obtain foods rich in protein. Moreover, the nurse needs to assess whether the patient values this intervention and is willing to make the necessary changes. Similarly, if the diet you recommend is unfamiliar to the patient who eats different foods for economic or cultural reasons, your intervention is unlikely to be successful. A nurse midwife recently shared that a colleague once took her aside and said, "You can't do that." Their practice was mainly for high-risk adolescent teens in a low-income area of the city, and she had just suggested that the patient buy organic kale to make smoothies. The colleague reminded her that the young woman lived in a food desert, might not own a blender, and was probably not the one who cooked in her family.

Nurse Variables

Nurse variables that influence the implementation of the care plan include levels of expertise, creativity (ability to match patient needs with specific nursing strategies), willingness to provide care, and available time. Focused Critical Thinking Guide 18-1 illustrates the importance of a nurse's ability to think critically about intervention strategies.

Resources

The most elaborately designed care plan cannot be fully effective without adequate staff, equipment, and supplies. These resources are all important determinants of patient care. The patient's financial resources and the adequacy of community-based resources also influence the care plan.

Scope of Practice and Current Standards of Care

All nursing actions for implementing the care plan must be consistent with the nurse's scope of practice and standards of care. See Chapter 19 for a discussion of these standards. All nurses are responsible for learning the standards that dictate practice in their specialty. Failure to practice according to these standards may result in a charge of negligence.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Research Findings

Nurses concerned about improving the quality of nursing care use research findings to enhance their nursing practice. Reading professional nursing journals and attending continuing education workshops and conferences are excellent ways to learn about new nursing strategies that have proved effective. Evidence-based practice resources online include the following:

- The Agency for Healthcare Research and Quality (AHRQ): http://ahrq.gov
- The Cochrane Effective Practice Organization of Care's reviews on effective quality improvement and implementation: http://epoc.cochrane.org
- *Toolkit: Implementation of Clinical Practice Guidelines*, available at the Registered Nurses' Association website, http://www.rnao.org
- Intervention Mapping, Step 5: Program Implementation Plan, available at the Intervention Mapping website, http://interventionmapping.com
- American Association of Critical-Care Nurses (AACN) Practice Alerts: https://www.aacn.org/clinical-resources/view-all-issues#page/1?%7B75C75579-1BCC-4DD7-9044-A01AB54B2FAD%7D%5B%5D=%7BFE23A6BE-FE7F-4E2D-B539-A6F2BA208E88%7D

18-1 Focused Critical Thinking Guide

INTERVENTION STRATEGIES

One of the nurses on the oncology unit where you have been working for 6 months since graduation wants to develop a "humor room" where patients, their families, and staff can "take a break" from the serious business of illness. Designed to lift the spirits, amuse, distract, and thus speed the healing process, humor rooms are gaining popularity as new therapeutic tools. Funny books, comic movies on a large-screen TV, games, and puzzles—and ideally, even clowns, magicians, musicians, and stand-up comedians—are being envisaged. Several nurses have vocally expressed their lack of support for the project and think the idea is "stupid" at best, and potentially a great waste of money, time, and energy that could be devoted to "tried and true" methods of healing. You have been asked to support the project and must decide how to respond.

1. Identify goal of thinking

Clarify your thinking about humor as a therapeutic measure so that you can decide whether to support this project.

2. Assess adequacy of knowledge

Pertinent circumstances: The nurse who wants to develop the humor room is more popular with patients than she is with her colleagues. Her nurse friends are quick to point out that while it's true that she is "a bit flaky" and unorthodox, she is an efficient nurse who is well loved by her patients and their families. The hospital is in the midst of cutting expenses and has laid off both professional and nonprofessional employees.

Prerequisite knowledge: To decide how you should respond in this situation, you need to research the healing benefits of humor. Are there clinical studies demonstrating its effectiveness as a therapeutic measure? If studies point to humor's effectiveness, you will need to determine: (1) what priority it should have among other treatment modalities and (2) the feasibility of creating a humor room in the current climate of cutting expenses. Is there a creative way to finance this venture?

Room for error: Since life and death do not hinge on how you elect to respond to this plea for support, there is a relatively wide margin for error. Because personal energy and finances are limited, however, you do not want to involve your unit in a futile project.

Time constraints: There is no rush for an immediate decision on your part, which gives you adequate time to develop the knowledge base you need to make an informed decision.

3. Address potential problems

The most serious obstacle to critical thinking in this situation would be the lack of an open mind and refusal to weigh the merits of a new treatment modality. Complicating factors include divided loyalties among the nurses and the tendency to support or refuse support for the project on the basis of whether one likes the nurse advocating the project, rather than on the merits of the project. Finally, the lowered morale caused by layoffs may squash all creativity and willingness to "dream new dreams."

4. Consult helpful resources

Your first challenge will be to learn more about humor as a healing measure. Ideally, you may be able to consult a local expert and invite the expert to meet with the staff. Alternatively, you can research the literature, looking for clinical studies and reports of the first-person experiences of others.

5. Critical judgment/decision

After a search of the literature that convinced you and some of the other nurses of the clinical benefits of humor,

you decide to explore the feasibility of developing a humor room. Your options are to "play it safe" and not rock the boat during a difficult period in the hospital by trying something new, or to become an advocate for the project and commit your energies to making it happen. You decide that a creative project may be exactly what the staff needs to rediscover the "joy of nursing" and begin to explore means to fund the project. You plan to "start small" and to reassess the project every 6 months. Since your research educated you about the potential benefits *and harms* humor can create, you decide that your first objective must be to educate the staff.

The evidence-based practice literature continues to identify the high demands of providing patient care and limits on available time, resources, and structures as barriers to evidence-based practice. It is important as you begin planning and implementing care for patients to perceive evidence-based practice as a consistent approach to providing safe, quality patient care, rather than an "extra duty" or student care plan demand (Mick, 2017). Read Bridges, McNeill, and Munro (2016) for an exhilarating description of how research published in the preceding year will lead to practice change in critical care, address challenges at the bedside, and introduce new care strategies.

Research in Nursing boxes throughout this text demonstrate the difference nursing research can make in improving patient outcomes. Proponents of nursing implementation science are beginning to address the challenges of implementing research findings into practice.

Ethical and Legal Guides to Practice

To practice good nursing, you need to be knowledgeable about the laws and regulations that affect health care and the ethical dimensions of clinical practice. Without this understanding, a sincere motivation to benefit the patient and a conscientious attempt to implement nursing orders will not be sufficient. Each nurse is responsible for becoming sensitive to the ethical and legal dimensions of practice, and moral and legal accountability are inherent in the practice of professional nursing.

Look back on the scenario presented at the beginning of the chapter for **Estelle Morrissey**. Ethical and legal guidelines are crucial in determining how the nurse intervenes. In addition, the nurse needs to evaluate the ethical and legal ramifications of their actions in light of the patient's request to die.

Chapters 6 and 7 discuss the ethical and legal dimensions of practice. Hospital risk managers and ethics committees are increasingly available as institutional resources for nurses.

CONTINUING DATA COLLECTION AND RISK MANAGEMENT

Sensitivity to how the patient is responding to nursing interventions and to the patient's progress toward outcome achievement allows the nurse to modify nursing interventions appropriately.

A vital nursing intervention is ongoing risk management. While monitoring the patient's responses to the care plan, nurses are also alert to the development of new problems that may result in the identification of new diagnoses or collaborative problems. As nurses get to know patients and recognize clusters of significant data, they can identify problems for which the patient is at risk and intervene appropriately to promote health and to prevent disease.

DOCUMENTING NURSING CARE

Remembering the legal truth, "It wasn't done if it wasn't documented," each nurse carefully documents all nursing interventions. See Chapter 20 for guidelines for written documentation, and see the nursing care plans at the end of clinical chapters for samples of documented nursing interventions.

WHEN A PATIENT DOES NOT COOPERATE WITH THE PLAN OF CARE

When a patient does not follow the plan of care despite your best efforts, it is time to reassess strategy. The first objective is to identify why the patient is not following the therapy. One possibility is that the care plan may not be right for this patient. In this event, what is needed is not a change in the patient but rather a change in the plan of care. If you

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

determine, however, that the care plan is adequate, you must identify and remedy the factors contributing to the patient's nonadherence. Common reasons for nonadherence include:

- Lack of family support
- Lack of understanding about the benefits of adherence
- Low value attached to outcomes or related interventions
- Adverse physical or emotional effects of treatment (such as pain and fatigue)
- Inability to afford treatment
- Limited access to treatment

Remember the difference between labeling patients "nonadherent" and judging them as "bad people" versus being open to understand the reasons for someone's failing to act on the care plan. Think about the effect on the patient both of these nursing responses to learning that a patient hasn't been taking his blood pressure medicines will have. "What's wrong with you? Don't you know that high blood pressure can kill you?" versus "Can you tell me why taking your medications as scheduled is so difficult for you? I would like to understand."

DELEGATING NURSING CARE

Because of the pressure to reduce health care costs and the increasing demand for nursing services in the midst of a critical shortage of professional nurses, many employers of nurses have increased their use of **assistive personnel (APs)**, sometimes referred to informally as "nurse extenders" or "techs." APs are people trained to function in an assistive role to the licensed registered nurse (RN) in the provision of patient activities as delegated by and under the supervision of the registered professional nurse. **Delegation** is the transfer of responsibility for the performance of an activity to another person while retaining accountability for the outcome. In some cases, the new mix of professional and nonprofessional staff is threatening patient safety. Never has it been more important for nurses to critically identify which nursing interventions require professional nurses and which can be safely delegated; this can be especially challenging for new nurses. See the Five Rights of Delegation in Box 18-2. Chapter 10 includes additional discussion of delegation, including the ANA's *Principles for Delegation.*

Review the patient scenario for **James McMahon**, the critically ill patient described at the beginning of the chapter and in "Reflective Practice: Challenge to Technical Skills." The nurse's ability to delegate effectively is important for providing safe, efficient care.

Box 18-2 **Five Rights of Delegation**

Right Task

- The activity falls within the delegatee's job description or is included as part of the established written policies and procedures of the nursing practice setting. The facility needs to ensure that the policies and procedures describe the expectations and limits of the activity and provide any necessary competency training.

Right Circumstance

- The health condition of the patient must be stable. If the patient's condition changes, the delegatee must communicate this to the licensed nurse, and the licensed nurse must reassess the situation and the appropriateness of the delegation.

Right Person

- The licensed nurse along with the employer and the delegatee is responsible for ensuring that the delegatee possesses the appropriate skills and knowledge to perform the activity.

Right Directions and Communication

- Each delegation situation should be specific to the patient, the licensed nurse, and the delegatee.
- The licensed nurse is expected to communicate specific instructions for the delegated activity to the delegatee; the delegatee, as part of two-way communication, should ask any clarifying questions. This communication includes any data that need to be collected, the method for collecting the data, the time frame for reporting the results to the licensed nurse, and additional information pertinent to the situation.
- The delegatee must understand the terms of the delegation and must agree to accept the delegated activity.
- The licensed nurse should ensure that the delegatee understands that they cannot make any decisions or modifications in carrying out the activity without first consulting the licensed nurse.

Right Supervision and Evaluation

- The licensed nurse is responsible for monitoring the delegated activity, following up with the delegatee at the completion of the activity, and evaluating patient outcomes. The delegatee is responsible for communicating patient information to the licensed nurse during the delegation situation. The licensed nurse should be ready and available to intervene as necessary.
- The licensed nurse should ensure appropriate documentation of the activity is completed.

Delegation and the Student Nurse

Student nurses may find that they have been delegated to provide care they cannot safely perform. Whenever you are asked by a staff nurse to perform an intervention for which you lack training, consult with your instructor to see if you can safely perform the intervention with supervision. Never attempt to perform interventions beyond your capacity without supervision, even if instructed to do so by a staff nurse. Review the Reflective Practice feature at the beginning of this chapter. Students who work as nursing assistants while enrolled in professional programs are especially likely to be asked to perform interventions beyond their mastery. You may be able to turn these requests into learning opportunities. For example, you might say, “I’ve never practiced that procedure but I’d love the opportunity to observe one of the experienced nurses do this.”

GUIDE FOR STUDENTS

Organizing Care

Student nurses organizing their nursing care in advance for a particular clinical day can use the guidelines for student clinical responsibilities in Box 18-3 to help identify nursing measures for which they will be responsible. In addition to these guidelines, working out a time schedule may provide clear direction for the clinical day and ensure that the patient’s needs are met. Some faculty require students to prepare clinical logs, which are also an excellent guide to organization. Figure 18-6 (on page 492) illustrates guidelines for a clinical log.

Source: Used with permission. National Council of State Boards of Nursing/American Nurses Association. (2019, April 1). National guidelines for nursing delegation. https://www.nursingworld.org/~4962ca/globalassets/practiceandpolicy/nursing-excellence/ana-position-statements/nursing-practice/ana-ncsbn-joint-statement-on-delegation.pdf

Box 18-3 **Organizing Student Clinical Responsibilities**

To organize clinical responsibilities, check:

1. Patient profile
2. Name by which patient wishes to be addressed
3. Patient’s chief complaint and reason for admission
4. Patient’s current health status: Note any physical or emotional changes indicating the need to modify the care plan.
5. Routine assistance patient needs to meet basic human needs
6. Priorities for nursing care:
   a. Priorities identified by the patient as “most important.” The nurse might state, “I’ll be your nurse until 3 PM, and I’m interested in learning what you would most like to accomplish today.”
   b. Prioritized nursing diagnoses/problems, patient outcomes, and related nursing interventions
   c. Medical orders that need to be implemented
   d. Interdependent or collaborative nursing responsibilities
7. Special “events” of the day that may require special observation of the patient, teaching, preparation, or aftercare:
   a. Diagnostic tests

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

b. Consultations with specialists
c. New therapies (physical therapy, medications, surgery, radiotherapy, and the like)

8. Special safety or risk management needs
9. Special teaching, counseling, or advocacy needs
10. Special needs of the family

Evaluation Criteria for Clinical Logs

Student	Date

Element/Criteria	Points possible	Score
Epidemiology of Primary Diagnosis • Incidence • Prevalence • Risk factors • Case-fatality rate	10	
Pathophysiology • Presented in understandable patient education terms • Brief explanation is congruent with actual physiologic processes of disease	10	
Tests/Procedures • Brief explanation of why indicated • Analysis of findings accurate • Pre-post patient education developmentally appropriate • Pre-post nursing interventions appropriate	10	
Medications • Provide a list of all medications that the patient is receiving • Brief explanation of the indication in terms that a patient would understand	10	
Physiologic/Psychosocial Assessment Summary • Assessment findings accurate • Includes physiologic, psychosocial, and spiritual findings (as identified)	10	
Nursing Diagnosis • 5 appropriate nursing diagnoses identified • Diagnoses presented in appropriate format • Priority nursing diagnosis selected is appropriate	10	
Nursing Process: Interventions/Rationale/Evaluation. (Determined by clinical faculty weekly) • Measurable goals established/short-term goal supports achievement of long-term goal but are not the same goal • Interventions are clear and concise and include frequency of action • Three appropriate interventions provided for each LT and ST goal • Rationales clearly support intervention in plan of care and are referenced • Evaluation statements for short-term goal are clear and concise (LTG not evaluated) • Unmet goals include action plan	20	
Self-Identified Strengths and Opportunities for Self Improvement • Congruent with Strengths Identified by Instructor	2	
National Patient Safety Goals: Identify one of the National Patient Safety Goals and how you addressed it during your shift (use a different one for each log).	4	
Cultural Considerations Appropriately Incorporated in Your Care with an Example	2	
Values: Describe an example of how your nursing care emulates the principles of Social Justice, Human Flourishing, OR Commitment to the Common Good that we stand for in the Department of Nursing at Georgetown University	4	
Professional Roles • Self-identities roles utilized in providing care	2	
Reflective Practice: Thought Question of the Week • Question posed by student upon reflecting on the day of care. May be based on patient care or condition, nursing, staff issues, etc.	2	
Format: Typed, spelling, grammar, APA for references	4	
Note: Papers are due within 48 hours. Please submit to your clinical faculty member via e-mail or Blackboard as per their preference. Rules for grading apply as with all NHS papers.	100

Nursing Oneself

It is difficult for nurses to be sincerely attentive to patient needs if their own human needs are not met. Make sure you come to your clinical rotation well rested and having had a nutritious meal. Because no one is perfectly healthy or "whole" all the time, nurses preparing for professional practice should spend time getting to know themselves. Activities that promote psychological health when practiced regularly include self-awareness, communication, time management,

preparation for crisis and loss, developing and maintaining support systems, and practicing self-care in all areas. The characteristics of emotional health include self-esteem, self-knowledge, satisfying interpersonal relationships, environmental mastery, stress management, a positive body image, a sense of humor, and the ability to experience pleasure. See related content in Chapter 1.

Nurses who want to be competent practitioners learn early to nurse themselves and other nurses before attempting to nurse patients. Good personal health enables nurses not only to practice more efficiently, but also to be a health model for patients and their families. Nurses can help patients to imitate good health behaviors and eventually integrate them into their daily life through the process of identification. Use the Promoting Health displays in each clinical chapter (Units VI and VII) for yourself as well as for your patients. You will also find Nurse Self-Care Alerts like the one below throughout the text.

Nurse Self-Care Alert

The Occupational Safety and Health Administration (OSHA) cites three factors that make hospitals such hazardous workplaces:

Unique risks: Hospital workers lift, reposition, and transfer patients who have limited mobility. Other unique risks include needlesticks and violence.

Unique culture: Caregivers feel an ethical duty to "do no harm" to patients. Some will put their own safety and health at risk to help a patient.

They are not assembly lines: Employees must react to unpredictable events with split-second decisions.

Read more at: https://www.osha.gov/dsg/hospitals/documents/1.1_Data_highlights_508.pdf.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in implementing the care plan, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following during the implementing phase of the nursing process:

- Did your commitment to engage your patients and families and to collaborate with your fellow students, instructor, and other members of the team as you implemented the care plan result in successful partnerships?
- Did your preparation result in your feeling confident about the nursing interventions you performed? Did your competence and confidence inspire the patient's and team's trust?
- Were you able to offer a scientific rationale for each intervention you employed (evidence-based practice)?
- Did your patients make real progress toward realizing expected outcomes as a result of your interventions?
- Did you need to modify the care plan as a result of ongoing assessments? Did you think of better interventions to produce the expected outcomes?
- Did your vigilance and awareness of potential error and omissions prevent error?

Perhaps the most important question to reflect on is: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to implement the care plan?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Team up with another student and take turns role-playing a nurse visiting an older man who is homebound and needs his vital signs and nutritional status assessed. Discuss with each other the truth or falsity of this claim: "*Who the nurse is*, is as important as, and sometimes more important than, *what the nurse does*."

. Receive the same clinical assignment as another student and independently outline your care priorities, specifying what you plan to accomplish during each of your clinical hours. Talk with the other student about the differences in what you both hope to accomplish and how you would do this. Try to imagine what these differences would mean to the patient.

. You are the only RN on a 50-bed wing in a long-term care facility. You have one LPN working with you and two personal care assistants. Each of the 50 residents requires assistance with activities of daily living, all take at least some medications, and most require monitoring for multiple chronic (and sometimes acute) illnesses. When the home is short-staffed, you are sometimes the only RN covering two 50-bed units. How will you decide which interventions to delegate?

. Describe how you would probably respond, and how you would like to respond (if these are different), to hearing another nurse in the shift report say that one of the patients you are assigned to was a real "PIB" ("pain in the butt") all day and "just impossible" to care for. Reflect on the importance of the language we use to report on a patient to one another.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

PRACTICING FOR NCLEX

. A school nurse determines that a student who has lost weight is at risk for an eating disorder and would benefit from a nutritional assessment. What action will the nurse take?

a. Perform a focused nutritional assessment
b. Seek direction from the student's health care provider
c. Suggest the student visit the nurse-run clinic
d. Request a consultation with a nutritionist

. A nurse is caring for a group of patients. Which actions are appropriate to include in the implementation phase of care? Select all that apply.

a. Changing the dressings on a burn victim's arm
b. Assessing a patient's nutritional intake
c. Formulating a nursing diagnosis for a patient with epilepsy
d. Turning a patient in bed every 2 hours to prevent pressure injuries
e. Checking a patient's insurance coverage at the initial interview
f. Determining availability of community resources for a patient with dementia

. Nurses use the Nursing Interventions Classification (NIC) Taxonomy structure as a resource to plan nursing care for patients. What information is found in this structure?

a. Case studies illustrating a complete set of activities that a nurse performs to carry out nursing interventions
b. Nursing interventions, each with a label, a definition, and a set of activities that a nurse performs to carry it out, with a short list of background readings
c. Complete list of nursing diagnoses, outcomes, and related nursing activities for each nursing intervention
d. Complete list of reimbursable charges for each nursing intervention

. A nurse works in a long-term care facility where standing orders are in place for influenza vaccines for all residents. What is the nurse's priority, when carrying out the prescriptions?

a. Assessing whether the patient previously received the vaccine
b. Refusing to give the vaccine without a written prescription
c. Determining if the standing orders are inappropriate for their unit
d. Calling the nursing supervisor to determine if this is a permitted action

. A nurse performs nurse-initiated nursing actions when caring for patients in a skilled nursing facility. Which reflect these types of actions? Select all that apply.

a. Administering an antibiotic to a patient with pneumonia
b. Consulting with a psychiatrist for a patient who misuses opiates
c. Checking the skin of bedridden patients for skin breakdown
d. Ordering a kosher meal for an orthodox Jewish patient
e. Recording a patient's intake and output
f. Preparing a patient for surgery according to facility protocol

. A nurse enters the patient's room to perform pin-site care for a patient wearing a halo vest to stabilize the cervical spine. What action will the nurse take first?

a. Administer pain medication
b. Reassess the patient
c. Prepare the equipment
d. Explain the procedure to the patient

. The charge nurse tells a nursing student to change a surgical dressing while they take care of other patients. The student has not changed dressings before and does not feel confident performing the procedure. What action should the student take?

a. Tell the charge nurse that they lack the technical competencies to change the dressing independently
b. Assemble the equipment for the procedure and follow the steps in the procedure manual
c. Ask another student nurse to work collaboratively with them to change the dressing
d. Tell the clinical instructor they have not had experience with the delegated task

. A nurse develops a care plan for an adolescent patient who gave birth to a premature infant. When presented with the collaborative care plan, including home health care visits, the patient states, "We will be fine on our own. I don't need any more care." What is the nurse's best response?

a. "You know your personal situation better than I do; I will respect your wishes."

b. “If you don’t accept these services, your baby’s health will suffer.”
c. “Let’s take a look at the plan again and see if we can adjust it to fit your needs.”
d. “I’m going to assign your case to a social worker who can explain the services better.”

. An RN working on a hospital unit frequently delegates patient care to assistive personnel (AP). Which activities are appropriate for the nurse to safely delegate? Select all that apply.

a. Performing patient assessments
b. Making patient beds
c. Giving patients bed baths
d. Administering oral medications
e. Ambulating patients
f. Assisting patients with meals

. A nursing student is prioritizing interventions for a patient with diabetes who needs diagnostic testing, dressing changes, meal planning and counseling, and assistance with hygiene. The patient states, “I must have my hair washed before I can do anything else; I’m ashamed of the way I look.” How will the student best prioritize this patient’s care?

a. Explain to the patient that there is not enough time to wash their hair today because of the busy schedule
b. Schedule the testing and meal planning first and complete hygiene as time permits
c. Perform the dressing changes first, schedule the testing and counseling, and complete hygiene last
d. Wash the patient’s hair and perform hygiene, schedule testing and counseling, then change the dressing

. A nurse is caring for a patient with a painful, non-healing surgical wound. The patient does not request pain medication because they do not want to be a burden. What actions will the nurse implement to improve pain relief? Select all that apply.

a. Reestablishing the pain level the patient finds acceptable as the pain management goal
b. Obtaining a dry-erase board to remind the patient of the plan of care
c. Assessing the patient’s pain and offering analgesia during hourly rounding
d. Placing the analgesic underneath other medications and quickly handing it to the patient
e. Asking the family members to speak to the patient about pain relief

. A nursing unit has adopted use of a care bundle for insertion of central venous catheters. During the procedure, which action by a nurse requires the charge nurse to intervene?

a. They discard the sterile drapes in the insertion kit.
b. The primary nurse reminds everyone in the room to wear a mask.
c. The team includes every item in the bundle during the procedure.
d. The nursing student states using the bundle improves patient outcomes.

ANSWERS WITH RATIONALES

. **a.** Performing a focused assessment is an independent nurse-initiated intervention, not requiring a prescription from or intervention by the health care provider, advanced practice nurse, or nutritionist.

. **a, d, f.** During the implementing step of the nursing process, nursing actions that were formulated during the planning process are carried out. The purpose of the implementation phase is to assist the patient in achieving valued health outcomes, for example promote health, prevent disease and illness, restore health, and facilitate coping with altered functioning. Assessing a patient’s nutritional status or insurance coverage occurs in the assessment step, and formulating nursing diagnoses occurs in the diagnosing/analyzing step.

. **b.** The Nursing Interventions Classification (NIC) Taxonomy lists nursing interventions, each with a label, a definition, a set of activities that a nurse performs to carry it out, and a short list of background readings. It does not contain case studies, diagnoses, or charges.

. **a.** Standard orders empower the nurse to initiate actions ordinarily requiring the order, prescription or supervision of a health care provider. The nurse first assesses whether the patient has already received the vaccine. The standing order is a valid prescription given to cover common, recurring actions the nurse can use when indicated.

. **c, d, f.** Nurse-initiated interventions, or independent nursing actions, include nurse-prescribed interventions resulting from their assessment of patient’s actual or potential health problems. Protocols and standard orders empower the nurse to initiate actions that ordinarily require the order or supervision of a health care provider. Consulting with a psychiatrist is a collaborative intervention.

. **b.** Before implementing any nursing action, the nurse returns to the first step of the nursing process, reassessing whether the action is still needed. Then the nurse may collect the equipment, explain the procedure, and, if necessary, administer pain medications.

. **a.** Student nurses should notify their nursing instructor or nurse preceptor if they believe they lack any competencies

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

needed to safely implement the care plan. Once educated and technically prepared, the nursing student may perform a dressing change.

- **c.** When a patient rejects the care plan, the nurse works to identify the underlying barriers. If the nurse determines that the care plan is adequate, the nurse works with the patient to formulate mutually developed goals and interventions.
- **b, c, e, f.** AP assist the RN to provide care as delegated by and under their supervision. Typical tasks delegated include actions for stable patients (e.g., vital signs hygiene, bed-making, ambulating patients, and helping to feed patients). Performing the initial patient assessment and administering medications are the responsibility of the RN.
- **d.** When time constraints and safety permit, priorities identified by the patient as most important are completed first. Washing the patient's hair and assisting with hygiene put the patient first, setting the tone for an effective nurse–patient partnership.
- **a, b, c.** The nurse reassesses the patient's knowledge and acceptance of the plan of care, including the level of pain the patient finds acceptable. Using a dry-erase board and hourly rounding further communicate and reinforce the care plan. The nurse develops a compassionate and trusting relationship with the patient; the nurse and patient mutually determine the plan for pain management, not their family.
- **a.** Care bundles are sets of evidence-based interventions that, when performed together and consistently, improve the process of care and patient outcomes. Discarding sterile drapes from the insertion kit circumvents this process.

Evaluating

Tyler Jameson

Tyler, a term neonate born 30 hours ago, has yet to pass stool. Follow-up assessment reveals that he does not have a patent anus, a finding that was not detected in the neonate's initial assessment.

Mioshi Otsuki

Mioshi, an older adult woman with a history of heart failure being treated with diuretics, is receiving home care. Questioned about her prescribed drug-therapy regimen, Ms. Otsuki states, "I take this one labeled 'furosemide' every day in the morning along with this other one labeled 'Lasix.'"

Nicholas Soros

Nicholas is a 68-year-old patient newly diagnosed with diabetes. His initial assessment revealed that he was about 50 lb overweight due to poor diet and lack of exercise. A plan was developed to help Mr. Soros better manage his diabetes through planned weight reduction and regular exercise. At a follow-up visit, assessment reveals a weight gain of 5 lb. He stated, "I'm too old to worry about diet and exercise. You can control my diabetes with medication, right?"

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe evaluation, its purpose, and its relation to the other steps in the nursing process.
. Evaluate the patient's achievement of four types of outcomes specified in the care plan.
. Manipulate factors that contribute to success or failure in outcome achievement.
. Use the patient's response to the care plan to modify the plan as needed.
. Explain the relation between quality-assurance/quality-improvement programs and excellence in health care.
. Describe the AACN's six essential standards for establishing and sustaining healthy work environments and the seven crucial conversations in health care.
. Value self-evaluation as a critical element in developing the ability to deliver quality thoughtful, person-centered nursing care.

structure evaluation

In the fifth phase of the nursing process, **evaluating**, the nurse and patient together measure how well the patient has achieved the outcomes specified in the care plan. When evaluating patient outcome achievement, the nurse identifies factors that contribute to the patient's ability to achieve expected outcomes and, when necessary, modifies the plan of care (Fig. 19-1 on page 500). The purpose of evaluation is to allow the patient's achievement of expected outcomes to direct future nurse–patient interactions. Based on the patient's responses to the plan of care, the nurse decides to:

- Terminate the plan of care when each expected outcome is achieved
- Modify the plan of care if there are difficulties achieving the outcomes
- Continue the plan of care if more time is needed to achieve the outcomes

When evaluation points to the need to modify nursing care, the nurse reviews each preceding phase of the nursing process (assessing, diagnosing, planning, and implementing). Successful evaluation helps ensure that valued patient outcomes are attained. It also enhances the public's image of nursing and promotes continued selection and funding of nursing services in the competitive health care market.

UNIQUE FOCUS OF NURSING EVALUATION

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

As members of the health care team, nurses are involved in many types of evaluation. Nurses measure patient outcome achievement, how effectively nurses help targeted groups of patients to achieve their specific outcomes, the competence of individual nurses, and the degree to which external factors—such as different types of health care services, specialized equipment or procedures, or socioeconomic factors—influence health and wellness. *The patient, however, is always the nurse's primary concern.* A nurse may perform a nursing procedure competently, creatively, and with care, but if this nursing intervention does not help the patient reach desired outcomes, it is not fully meaningful. Either directly or indirectly, the aim of all nursing evaluation is quality nursing care that aids patient outcome achievement. Therefore, the most important act of evaluation performed by nurses is evaluating outcome achievement with the patient (see the Reflective Practice box for an example).

The Institute of Medicine (IOM)'s Committee on Quality of Health Care in America is educating the public about what patients can reasonably expect from their health care (Box 19-1 on page 500). (Note the IOM was renamed the National Academy of Sciences, Engineering, and Medicine in 2015.) Even beginning nurses can use these guidelines to evaluate the care they are providing.

CLINICAL REASONING AND JUDGMENT AND EVALUATING

The five classic elements of evaluation are:

. Identifying evaluative criteria and standards (what you are looking for when you evaluate—i.e., expected patient outcomes)
. Collecting data to determine whether these criteria and standards are met
. Interpreting and summarizing findings
. Documenting your judgment
. Terminating, continuing, or modifying the plan

Each element requires the nurse to use critical thinking and clinical reasoning and judgment about how best to evaluate the patient's progress toward valued health outcomes. In the nursing process, evaluative criteria are the patient outcomes developed during the planning phase. Because patient outcomes reflect desired changes in patient status, and because nursing actions are directed toward these outcomes, they are the core of evaluation in thoughtful, person-centered nursing practice. Determining whether patient outcomes have been or are being met and then identifying the appropriate nursing response are the functions of evaluation.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO INTERPERSONAL SKILLS

I first met Mr. Nicholas Soros, a 68-year-old patient newly diagnosed with diabetes, in the clinic. He was about 50 lb overweight, and his health history revealed the need for major dietary changes and an exercise program. The interdisciplinary team devised a plan to help Mr. Soros better manage his diabetes through planned weight reduction and regular exercise, for which I did much of the initial teaching. Unfortunately, when Mr. Soros returned for his next checkup, he had gained 5 additional pounds and reported being "too old" to worry about diet and exercise. "You can control my diabetes with medication, right?" When I reported this to the nurse practitioner, he told me that Mr. Soros knows what to do and now it is his responsibility. I wasn't perfectly comfortable with this response and thought that Mr. Soros needed more than someone wagging a finger in his face.

Thinking Outside the Box: Alternate Courses of Action

- Remind Mr. Soros of what he needs to do and tell him that responsibility for this is his!
- After I make sure that he does indeed know what to do, spend time making sure that he values his health sufficiently to try these new behaviors.
- Make sure that Mr. Soros trusts us sufficiently to value working with us to achieve his health goals.

Evaluating a Good Outcome: How Do I Define Success?

- Mr. Soros achieves his target weight and is faithful to a program of regular exercise.
- Mr. Soros feels that his independence and ability to determine his own life plan are respected, at the same time feeling that we care about his health status.
- I learn more about developing a trusting nurse–patient relationship, exploring the relationship's role in helping patients to achieve valued health outcomes.

Personal Learning: Here's to the Future!

I learned something about myself and an important distinction between teaching and counseling. Clearly, just teaching Mr. Soros about diet and exercise wasn't sufficient. Mr. Soros was in no way going to change his lifestyle until he valued his health enough to make needed changes, including understanding why these changes were important. I also learned how important nurse–patient relationships are. When Mr. Soros came for his third visit, he asked the nurse who greeted him where I was, telling her "I want to see that nurse who cared about me!"—positive reinforcement for the relationship's importance.

Megan Kyle, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your competencies for professional practice? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Describe the type of teaching plan that the nursing student may have used at the initial teaching session. How might that teaching plan have changed based on the patient's response at the next visit? Would the outcomes identified initially need to be revised based on any changes in the teaching plan? Explain why or why not. What *knowledge, skills,* and *attitudes (KSAs)* do you need to develop to continuously improve the quality and safety of care for patients like Mr. Soros?

Patient-Centered Care: How can you establish a successful partnership with a patient who lacks the motivation to make critical lifestyle changes?

Teamwork and Collaboration/Quality Improvement (QI): When colleagues aren't willing to go that "extra mile" to work with vulnerable patients, how can you intervene successfully? What needs to change to improve quality in this setting? What does quality care for Mr. Soros "look like"?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Mr. Soros? What safety needs does he have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Mr. Soros's record to support safe patient care and coordination of care? Are there any apps that might be useful in coaching Mr. Soros? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

FIGURE 19-1. Evaluating. The nurse and patient together measure how well the patient has achieved the outcomes specified in the plan of care. Factors that contribute to the patient's success or failure are identified, and the plan of care is modified if necessary. Patient responses to the plan of care determine whether nursing care is to be continued as is, modified, or terminated. (*Source:* Used with permission from Shutterstock. *Photo by Joe Mitchell*.)

Box 19-1 **What Patients Should Expect From Their Health Care**

1. **Beyond patient visits:** You will have the care you need when you need it … *whenever* you need it. You will find help in many forms, not just in face-to-face visits. You will find help on the Internet, on the telephone, from many sources, by many routes, in the form you want it.
2. **Individualization:** You will be known and respected as an individual. Your choices and preferences will be sought and honored. The usual system of care will meet most of your needs. When your needs are special, the care will adapt to meet you on your own terms.
3. **Control:** The care system will take control only if and when you freely give permission.
4. **Information:** You can know what you wish to know, when you wish to know it. Your medical record is yours to keep, to read, and to understand. The rule is: "Nothing about you without you."
5. **Science:** You will have care based on the best available scientific knowledge. The system promises you excellence as its standard. Your care will not vary illogically from doctor to doctor or from place to place. The system will promise you all the care that can help you, and will help you avoid care that cannot help you.
6. **Safety:** Errors in care will not harm you. You will be safe in the care system.
7. **Transparency:** Your care will be confidential, but the care system will not keep secrets from you. You can know whatever you wish to know about the care that affects you and your loved ones.
8. **Anticipation:** Your care will anticipate your needs and will help you find the help you need. You will experience proactive help, not just reactions, to help you restore and maintain your health.
9. **Value:** Your care will not waste your time or money. You will benefit from constant innovations, which will increase the value of care to you.

10. **Cooperation:** Those who provide care will cooperate and coordinate their work fully with each other and with you. The walls between professions and institutions will crumble, so that your experiences will become seamless. You will never feel lost.

Think back to **Nicholas Soros**, the 68-year-old man diagnosed with diabetes who needs to lose weight and to exercise. The outcomes identified initially most likely focused on weight loss and adherence to an exercise program. Teaching at this initial visit also focused on ways to achieve these outcomes. However, the patient's statements and weight gain on his next clinic visit would lead the nurse to the conclusion that the outcomes identified were not being achieved. Therefore, some changes in the patient's care plan are necessary.

Identifying Evaluative Criteria and Standards

Although the terms *criteria* and *standards* are often used interchangeably in reference to the evaluation step, they have distinct definitions. **Criteria** are measurable qualities, attributes, or characteristics that identify skills, knowledge, or health states. They describe acceptable levels of performance by stating what is expected of the nurse or the patient. Chapter 17 describes how patient criteria are identified and formulated as patient outcomes.

Standards are the levels of performance accepted by and expected of nursing staff or other health team members. They are established by authority, custom, or consent. A good example of standards is the American Nurses Association's (ANA's) *Nursing: Scope and Standards of Practice* (2021), which you read about in Chapter 1. Be sure to be familiar with the evaluation competencies for registered nurses outlined in Standard 6, Evaluation. Chapters 17 and 18 describe *clinical practice guidelines,* a term used interchangeably with standards and protocols, all of which describe how care should be managed in certain situations. The goal is to design and deliver nursing care that evidence supports as likely to produce the expected patient outcomes (i.e., **evidence-based practice**).

Collecting Evaluative Data

The nurse collects evaluative data to determine whether or not the patient has met the desired outcomes. While the nurse collects data in the nursing assessment to identify patient health problems, the data collected in the evaluation step are used to determine whether the identified health problems have been or are being resolved through outcome achievement.

Consider **Mrs. Otsuki**, the older adult who is inadvertently taking double the dose of prescribed diuretic. This initial assessment indicates a need for teaching. Thus, when evaluating outcome achievement for this patient, the nurse would determine whether the patient demonstrates understanding of her drug-therapy regimen and is no longer taking two doses of the same drug.

This section discusses (1) the different types of data collected to evaluate the achievement of different types of patient outcomes and (2) time criteria for data collection.

Types of Outcomes

Nurses write outcomes during the planning phase of the nursing process. Chapter 17 describes four types of outcomes: cognitive, psychomotor, affective, and physiologic. The type of patient data collected to support the evaluation of

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

outcome achievement depends on the nature of the outcome. The data collected to determine the degree of outcome achievement are recorded in the corresponding evaluative statements (Box 19-2 on page 502).

Time Criteria

In addition to knowing *what type* of data to collect to determine outcome achievement, the nurse needs to know *when* to collect the data. When the patient outcomes were developed, a time frame was established for determining whether the specified changes have been achieved. At the designated time, the nurse, in collaboration with the patient, the family, and other members of the nursing team, evaluates the patient's attainment of the outcome. If outcomes are developed in observable and measurable terms, the task of collecting data for evaluation is clear-cut. Examples of three types of time criteria follow:

- By 7/8/25, the patient will walk the length of the hallway with support of a walker.
- Beginning 7/8/25, the patient will demonstrate a weight loss of 3 lb per month until target weight (135 lb) is achieved (6/8/25, weight: 151 lb).
- Before discharge, parents will correctly demonstrate chest physiotherapy procedures for patient.

Nurses should evaluate patient outcome achievement as early as possible. Celebrating outcome attainment with the patient usually helps encourage the patient and leads to further outcome achievement. When failure to meet designated outcomes is detected early, the care plan can be modified to remedy the failure.

Think back to **Nicholas Soros**, the 68-year-old patient with diabetes. By recognizing the lack of outcome achievement on the next visit, the nurse can gather additional data to revise the care plan. For example, perhaps Mr. Soros did not completely understand the nurse's teaching. Or, he may have had difficulty accepting his diagnosis, thereby interfering with his ability to comply with the plan, ultimately leading to weight gain instead of a weight loss.

The most common mistake nurses make when evaluating in acute care settings is waiting until the day the patient is to be discharged before evaluating outcome achievement. At that point, it is too late to revise the care plan.

Box 19-2 Evaluating Four Types of Outcomes in the Plan of Nursing Care

Diagnosis/Problem

Readiness for effective parenting; etiologic factor: no previous experience in childrearing (fear)

Assessment Data

Subjective: "My husband and I are both afraid we won't know what to do when we get the baby home"

Objective: Both parents are single children, report no childrearing experience; healthy newborn son delivered 2/4/25; first born

Strengths

VIB (very important baby): parents are both 38; history of infertility with one miscarriage; strong motivation to learn and use good parenting skills; strong support network

Expected Outcomes	Nursing Interventions	Evaluative Statement (Actual Outcomes)
Psychomotor Outcomes		
Before discharge, parents will demonstrate confidence in: • Holding baby • Diapering, dressing baby	Assess both parents' knowledge of childrearing practices; identify and reinforce motivation to learn; correct any	2/6/25 Outcome partially met. Both parents have correctly demonstrated safe techniques for holding, dressing, and

• Bathing baby • Feeding baby	misinformation. Develop and implement at a time convenient for both parents a teaching plan to include: • The primary nurse role-modeling techniques for comfortably and safely holding, talking to, and dressing baby • Parents independently viewing videos on: baby care, baby bath, and breastfeeding, followed by one-on-one discussion • Class for new parents: nurse to demonstrate baby bath and discuss general principles of care • Primary nurse observing mother and infant during initial feeding sessions and offering teaching and support as necessary	bathing baby. Mother is still concerned baby is not getting enough milk. *Revision:* Continue to spend time with mother and infant during feeding—provide positive reinforcement. *F. Morales, RN*
Cognitive Outcomes		
By 2/6/25, parents will report appropriate action to be taken if questions or problems arise after discharge: • Name and number of primary nurse • Name and number of pediatrician • La Leche League contact and number	Answer parents' questions and address related concerns. Assess parents' knowledge of infant problems frequently encountered by new parents. Inform parents of available community resources and describe appropriate action to take if questions or problems arise.	2/6/25 Outcome met. Parents discussed some infant problems related to feeding, elimination, and illness and reported appropriate community resource to contact. *F. Morales, RN*
Affective Outcome		
Before discharge, parents will verbalize decreased anxiety in regard to caring for son.	Assess parents' level of anxiety and potential negative effects on childrearing. Discuss this with parents. Explore adequacy of parents' coping strategies—increased knowledge, practice in supportive environment, community resources. Counsel as necessary. Compliment parents on new parenting skills. Allow for ventilation of anxiety or specific fears. Respond with teaching or emotional support, as necessary.	2/6/25 Outcome partially met. Except for concern about breastfeeding, *both* parents expressed feeling comfortable and eager to care for their son at home. *F. Morales, RN*
Physiologic Outcomes		
At 1-month postpartal telephone interview, 3/4/25 (by parents' report), the baby will demonstrate adequate: • Weight gain (birth weight, 7 lb	Use a 1-month postdelivery telephone interview to assess the adequacy of parenting skills. With positive report of growth and	3/4/25 Outcome met. Parents' report of baby's weight gain and behavior indicates good parenting skills. *F. Morales, RN*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

6 oz)
- Sleep–wakefulness patterns
- Comfort level indicating adequate parenting

development, compliment (reinforce) the parents.
With negative report, teach or counsel and refer as appropriate.

Interpreting and Summarizing Findings

Before the nurse can make a judgment about the patient's achievement of outcomes, it is necessary to study and interpret the data collected. Just as clusters of data are interpreted before the nurse identifies and validates a nursing diagnosis/problem, so too do evaluative data need to be interpreted. For example, a patient who is expected to walk the length of the hallway with support of a walker asks to be taken back to her room because she feels weak. The nurse must gather more data to determine if this is a one-time incident linked to medications or a temporary metabolic imbalance, or whether it signals a consistent inability to achieve this goal. Interpreting evaluative data requires clinical reasoning and judgment and is a skill that must be practiced.

When interpreting and summarizing findings, consider factors that influence outcome achievement. Numerous patient, nurse, and health care system variables contribute positively or negatively to patient outcome achievement. Identifying these variables allows the nurse to reinforce positive factors by drawing on them in the future, as well as to deal with other variables that are creating problems. The more sensitive and responsive nurses are to these variables, the more rewarding their practices will be.

Examples of positive factors include a patient's strong motivation to learn new health behaviors, a nurse who comes to work well rested and with a new care idea learned from a nursing journal, and a health care institution or facility that offers incentives for quality nursing and has an optimal nurse-to-patient ratio.

A nurse who understands what factors are helpful to the patient who is trying to reach desired outcomes can often manipulate these factors. For example, if a patient is learning to ambulate independently after hip surgery and you notice that he seems to make his best effort when his wife is present, mention this to her and plan to ambulate the patient at least once a day when she is present. Conversely, if a patient seems more fearful when his wife is present, note in the care plan that ambulation is best attempted when the patient's wife is not on the unit. Ideally, this fear would be explored with the patient before discharge so that he can continue to make progress when he is discharged home with his wife.

Table 19-1 (on page 504) presents variables that may negatively influence patient outcome achievement. Nurses need to think critically about the effects of these variables and respond creatively to them.

Documenting Your Judgment

After the data have been collected and interpreted to determine patient outcome achievement, the nurse makes and documents a judgment summarizing the findings. This is termed the **evaluative statement**. The two-part evaluative statement includes a decision about how well the outcome was met, along with patient data or behaviors that support this decision. Outcomes may have been met, partially met, or not met:

- 1/21/25—Outcome met. Patient reports 1 week of no tobacco use. C. Taylor, RN
- 1/21/25—Outcome partially met. Patient reports decreasing tobacco use from one pack per day to 4 to 6 cigarettes per day. Continue to implement and monitor plan. C. Taylor, RN
- 1/21/25—Outcome not met. Patient reports no change in tobacco use. Revision: Reexplore patient's commitment to try tobacco-use control strategies and adequacy of personal support systems to eliminate tobacco use. C. Taylor, RN

The nurse signs and dates the evaluative statement (see Box 19-2) or follows the documentation guidelines specified in the institution's computerized documentation systems.

Unfolding Patient Stories: Sara Lin • Part 2

Recall **Sara Lin**, from Chapter 2, who is on the medical-surgical unit following an appendectomy. Her indwelling urinary catheter was discontinued, and she can begin oral fluids and advance activity, as tolerated. How would the nurse evaluate that Sara is tolerating oral fluids? How would the nurse evaluate that her activity, fluid intake, and urine output are adequate?

Care for Sara and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

Modifying the Care Plan

When evaluation reveals that the patient has made little or no progress toward outcome achievement, the nurse needs to reevaluate each preceding step of the nursing process to try to identify the contributing factors causing problems with the care plan. New assessment data may need to be collected, diagnoses may be added or altered, outcomes may need to be modified or rewritten, nursing orders may be changed, or evaluation may be targeted more frequently.

Remember **Tyler Jameson**, the neonate who has not passed any stool after 30 hours. The initial outcome may have stated that the neonate would pass stool within 18 to 24 hours after birth. However, this outcome was developed based on data that was inaccurate. Therefore, the nurse, learning of the new data, would revise the outcome to correlate with the neonate's condition, dependent on the treatment to correct the anomaly.

Review the checklist in Box 13-9 (on page 370) for help in evaluating your use of the nursing process. Table 19-2 (on pages 505–506) suggests appropriate nursing responses to common problems encountered during evaluation of each step in the nursing process.

Table 19-1 Patient, Nurse, and Health Care System Variables That May Detract From Quality Nursing Care

VARIABLES	POSSIBLE SOLUTIONS
Patient Variables	
Patient who is physically and cognitively capable of self-care gives up, refuses to cooperate with therapeutic regimen, or thwarts the regimen	Identify one nurse who is able to develop a trusting relationship with the patient and determine the reason underlying the observed behavior: • No longer finds meaning and purpose in life • Overwhelming sense of powerlessness • Previous history of being "hurt," "exploited," "cheated" by the health care system • Inability to accept illness and related lifestyle changes Counsel appropriately. Use a team conference to develop a consistent plan of nursing care.
Patient who quietly accepts whatever is done or not done for him or her; seldom communicates needs or dissatisfaction	Note on the care plan the need to assess this patient thoroughly because the patient will probably not advocate for self. Educate the patient to become a more assertive health care consumer.
Nurse Variables	
Nurse who sincerely desires to give 150% all the time and who becomes quickly frustrated when observing substandard care; may feel alienated from other staff; excellent candidate for burnout	Learn to give quality care during designated work period; leave on time; avoid the temptation to do the work of others; leave work concerns at work. After establishing a reputation for delivering quality nursing care, seek creative solutions for nursing problems (strategies to increase nursing resources, motivation, morale) and try them—hopefully with a support network. View concerns as challenges rather than overwhelming obstacles.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	Develop a realistic sense of how much nursing care and of what quality can be delivered with existing resources. If resources do not permit quality care, explore change strategies within the institution. If administration is not supportive, explore other practice settings.
Nurse with overwhelming outside concerns: • Preparation for marriage, childbirth, divorce • Illness (self or family members) • Role conflict (familial roles, school, work, and the like) • New apartment, house	During periods of peak demand, may need to accept less than optimal performance at work. If this becomes the norm rather than the exception, carefully evaluate priorities. May need to cut work hours rather than "cheat" patients.
Nurse who is bored	After reflection, write down *personal* objectives related to work. Explore avenues within work setting for professional growth and development: initiate changes in nursing unit to improve patient care and to stimulate peer development; join institutional committees; participate actively in staff development programs; develop patient and family support groups. Look for new position that offers new challenges within or outside the institution. Join professional organizations and participate actively. Evaluate educational goals and explore possibilities—continuing education programs and degree work.
Health Care System Variables	
Inadequate staffing	Develop and use a patient classification system that incorporates an identification of the kind and amount of nursing services required. Record staffing patterns and relate to needs for nursing care and patient outcomes. Clearly demonstrate and document that adequate staffing makes a difference. Present these data to nursing administration with the request for additional staff. If necessary, use professional bargaining unit.
Nursing administration has sold out nursing; insensitivity to nursing demands within the institution	It may be impossible to practice quality, progressive nursing in this environment. If there seems to be no hope for change after appropriate channels have been explored, look for a new practice setting. Evaluate the new setting on the basis of what experience has taught you.

Table 19-2 Common Problems Noted During Evaluation of the Nursing Process

PROBLEM	NURSING RESPONSE
Assessing	
1. Inaccurate database → inaccurate nursing diagnoses/problems and a distorted care plan	1. a. Identify the patient or nurse variables responsible for inaccuracy. b. Revise the recorded database.
2. Database does not reflect changes in patient condition	2. Review with the entire nursing staff the importance of making assessment a priority in every patient interaction as well as the recording of the new data obtained.

3. Database is superficial: • Fails to communicate uniqueness of patient • Lacks sufficient detail on major problems or developments	3. a. Rethink the critical relation between an adequate database and quality care. b. Develop interviewing and physical assessment skills. c. Begin to identify the key data that need to be collected for specific nursing and medical diagnoses and problems and assess patient response to therapeutic regimen.
Diagnosing/Problem Identification	
1. General sense that nursing diagnoses/problems are "common sense" and, therefore, do not need to be put in writing → failure to address patient's real problems	1. Carefully develop and record priority nursing diagnoses/problems for several patients and fairly evaluate whether this makes a difference in terms of the continuity of quality care.
2. General sense that nurses are too busy doing treatments, "passing meds," and documenting care to develop nursing diagnoses/problems carefully → independent dimension of nursing remains underdeveloped	2. Examine practice and see whether independent nursing has a place; what percentage of every day is devoted to independent nursing functions? If this percentage is nonexistent or small, there understandably may be no felt need for nursing diagnoses/problems—but a desperate need to revise practice priorities.
3. Nursing diagnoses/problems are too vague to be helpful → routinized patient care	3. a. Revise the problem statement to describe more accurately what is unhealthy about the patient (the behavior that needs to be changed). b. Revise the etiology to more accurately identify what is making the problem a problem—this should be a guide to nursing intervention.
4. Nursing diagnoses/problems are not up to date → no one uses the care plan	4. Have a process for periodically reviewing the care plan to delete diagnoses/problems when problems have been resolved and to add a new diagnosis/problem as needed.
Planning	
1. The care plan contains only the standard knowledge most nurses would know without a written plan	1. Make use of standardized (computerized) plans as a basis for care planning. Devote nursing energies to individualizing this plan.
2. The long-term goal is vague, standard; fails to make clear the discharge goal for this patient	2. Practice writing specific long-term goals that clarify for all nurses the aim toward which all nursing care is directed (e.g., patient returns home ambulatory with walker, right hip incision healing, able to manage activities of daily living with minimal assistance from spouse).
3. The nursing outcomes, even if met, do not necessarily guarantee a resolution of the patient problem	3. When writing goals, it often helps to develop outcomes related to etiologic factors. Because the stated etiology may be incomplete or inaccurate, at least one outcome must be written so that if it is achieved, the problem in the nursing diagnosis is resolved.
4. The outcomes are incorrectly developed; progress toward goal achievement is difficult to evaluate	4. After writing outcomes, check them against the following criteria: • Subject is the patient or some part of the patient. • The patient behavior is stated in observable, measurable terms. • Criteria of acceptable performance are specified. • Time criteria are included in notes.
5. Nursing orders are superficial → patient receives	5. Review nursing orders to ensure that they

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

routinized care	indicate the specific nursing strategies or interventions most likely to result in successful outcome achievement for this patient (e.g., particular comfort measures that are successful adjuncts to analgesic administration for a particular patient). In specifying the "who, what, when, where, how, and how much" of nursing interventions, be sure to list the type of equipment and supplies needed in various treatments. As new patient data are obtained, update nursing orders. Delete inappropriate or unnecessary orders.
6. The initial care plan fails to be updated → care plan will not be consulted by nurses—if used, it will be to patient's detriment	6. If personal accountability for updating plan fails, develop a process on the nursing unit to ensure care plan review and revision.
7. The care plan addresses the immediate needs of the patient but fails to anticipate discharge needs → patient returns home unable to manage self-care activities	7. Work hard at developing the ability to project yourself into the patient's home after discharge. Learn to anticipate problems and concerns and prepare the patient and family for these. Use all discharge resources in the institution. Learn from patients what their needs were after previous discharge.
Implementing	
1. Nurses are not aware of patient priorities and the care plan; lack of continuity; inefficient use of nursing resources → patient fails to achieve goals/outcomes	1. a. Use shift report to update staff on status of priority nursing diagnosis and concomitant nursing care. b. Review care plan and nursing notes before beginning care.
2. Nursing care becomes routine and mechanized → patient never has the sense of being personally known by nurses	2. Explore creative strategies to make quality nursing care on this particular unit a challenge rather than a burden; use ongoing education, problem-solving strategies by the nursing team, gaming, and other incentives.
3. Documentation is inadequate → because there is no complete written record of nursing care, legally this care was never provided	3. a. Develop the philosophy that quality nursing care deserves to be documented. Review legal reasons for careful documentation. b. Become familiar with the flow sheets and note format used within the work setting so that charting can be done quickly and comprehensively.
Evaluating	
1. It is not done → mastery of nursing process is stunted; severely limits accomplishment of nursing aims	1. Develop the belief that quality nursing care does not happen automatically and that only ongoing evaluation will identify needed areas of revision. Devise an evaluative strategy and carry it out. Study its effect on quality of care after 6 months' implementation.

After identifying the factors contributing to the outcomes not being achieved, use the evaluative statement to suggest necessary revisions in the care plan. Revisions may include (1) deleting or modifying the nursing diagnosis/problem, (2) making the outcome statement more realistic, (3) increasing the complexity of the outcome statement, (4) adjusting time criteria in the outcome statement, or (5) changing the nursing intervention(s). Increasing the complexity of an outcome after it has been achieved facilitates optimal function. For example, the initial outcome for a patient with the diagnosis Impaired Mobility might be "patient transfers from the bed to the chair." After this is achieved, however, the outcome needs to be stepped up in complexity to "patient walks around room with support of walker."

The following is an example of a specified outcome for a resident in long-term care: "Resident will participate in a minimum of two planned social activities per week beginning 9/16/25." If the resident did not meet that outcome, this evaluative statement may be written: "9/27/25—Outcome not met. Resident chose not to participate in any group

activities this week." Many courses of action are then available to the nurse. Possible revisions to any care plan include the following:

- *Delete or modify the diagnosis/problem.* In the example, lack of participation in social activities may not be a problem or concern for the resident. The nurse should evaluate and validate data pointing to the diagnosis/problem.
- *Make the outcome statement more realistic.* The nurse would carefully determine the resident's need for activities and ability or desire to participate in activities.
- *Adjust time criteria in outcome statement.* The nurse might reevaluate after 3 weeks. The resident may need more time to adjust to living in an institution, as well as more encouragement.
- *Change nursing interventions.* The nurse could make a special effort to become familiar with the resident's interests, and match these with available programs and activities.

Once the nurse—ideally, in partnership with the patient—makes a decision about how to respond, this must be communicated to the patient or the patient's surrogate and to other members of the professional caregiving team, via the patient's record.

Think back to **Mioshi Otsuki**, the older adult taking too much diuretic medication. The home care nurse would work with the patient to develop a teaching plan about her heart failure, specifically related to her drug-therapy regimen. This plan then would be documented in the patient's record and communicated to all people involved in the patient's care, such as other home care facility nurses who may be on call or filling in to visit the patient, or home health aides involved in providing personal care and hygiene for the patient.

EVALUATING QUALITY CARE

In addition to each nurse's evaluation of patient outcome achievement and subsequent modifications to the care plan, many informal and formal mechanisms are used to ensure quality nursing care.

Performance Improvement in Everyday Clinical Practice

Nurses sometimes discover problems with the delivery of nursing care in their practice setting. The IOM's Committee on Quality of Health Care in America suggests 10 rules to redesign and improve care:

. Care based on continuous healing relationships
. Customization based on patient needs and values
. The patient as the source of control
. Shared knowledge and the free flow of information
. Evidence-based decision making
. Safety as a system priority
. The need for transparency
. Anticipation of patient's needs
. Continuous decrease in waste
. Cooperation among clinicians

Each nurse must decide how to respond when compromised patient care has been identified. Nurses committed to healthier patients, quality care, reduced costs, and the personal satisfaction of knowing that they are *actually making a difference* versus merely *wishing things were different* value **performance improvement**. The following four steps are crucial in improving performance:

. Discover a problem
. Plan a strategy using indicators
. Implement a change
. Assess the change; if the outcome is not met, plan a new strategy

See Box 19-3 for an example of a performance-improvement strategy. In this example, oncology nurses believe that advance directives are not being used optimally to improve end-of-life care for the seriously ill and dying. Remember, the central focus of these efforts is always improving the patient's experience and outcomes. The Institute for Healthcare Improvement (2018) has created a model for a Quality Improvement Charter, the guiding document that helps a team

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

structure its improvement project and develop and communicate a shared vision. The charter begins to answer the three essential questions of the Model for Improvement:

Box 19-3 Example of Steps in Performance Improvement

The following four steps are crucial in improving performance:

1. **Discover a problem.** Advance directives are a powerful legal tool for people to indicate their end-of-life care preferences. Nurses on an oncology unit are becoming frustrated because many of the patients on their unit lack advance directives. By the time decisions need to be made about ventilators, coding, dialysis, and so forth, patients are often no longer able to communicate their preferences. The hospital has a policy about advance directives, but no one seems to be taking responsibility for initiating discussions with patients when they are first admitted—or in the outpatient setting.
2. **Plan a strategy using indicators.** The nurses call an interdisciplinary meeting with the oncologists, social workers, and spiritual caregivers, who decide that the nurse case manager will be responsible for working with patients on admission to see if they want help in preparing an advance directive. Each case manager will be responsible for documenting within 48 hours of admission the patient's decision regarding an advance directive. Staff nurses will be able to direct patient and family requests to do advance planning to the case manager and appropriate team members. The ethics committee was asked to do an in-service on advance directives for the team.
3. **Implement a change.** Case managers begin assuming this responsibility, and one nurse volunteers to monitor progress at 3-month intervals by checking charts for advance directive content and by speaking with the staff nurses who voiced the initial frustration about decision making.
4. **Assess the change.** If the goal is not met, plan a new strategy. At the end of 6 months, everyone seems satisfied that the new plan is working, but a decision is made to schedule a 6-month follow-up evaluation to prevent backsliding.

- What are we trying to accomplish?
- How will we know that a change is an improvement?
- What change can we make that will result in improvement?

See their website for a helpful template (http://www.ihi.org/resources/Pages/Tools/QI-Project-Charter.aspx).

An important resource for nurses committed to performance improvement is the Quality and Safety Education for Nurses (QSEN) project. The overall goal of the QSEN Institute initiatives is to prepare nurses with the knowledge, skills and attitudes (KSAs) necessary to continuously improve the quality and safety of their health care systems. Visit the QSEN website, www.qsen.org, to view a variety of educational materials.

Peer review, the evaluation of one staff member by another staff member on the same level in the hierarchy of the organization, is an important mechanism nurses can use to improve their professional performance. This can be done formally or informally by inviting a peer you respect to give you feedback on nursing skills you are trying to develop—for example, "How do you think that session went with the patient's daughter? She's been so critical of us and I'm trying to understand the situation from her point of view and respond appropriately."

Establishing and Sustaining Healthy Work Environments

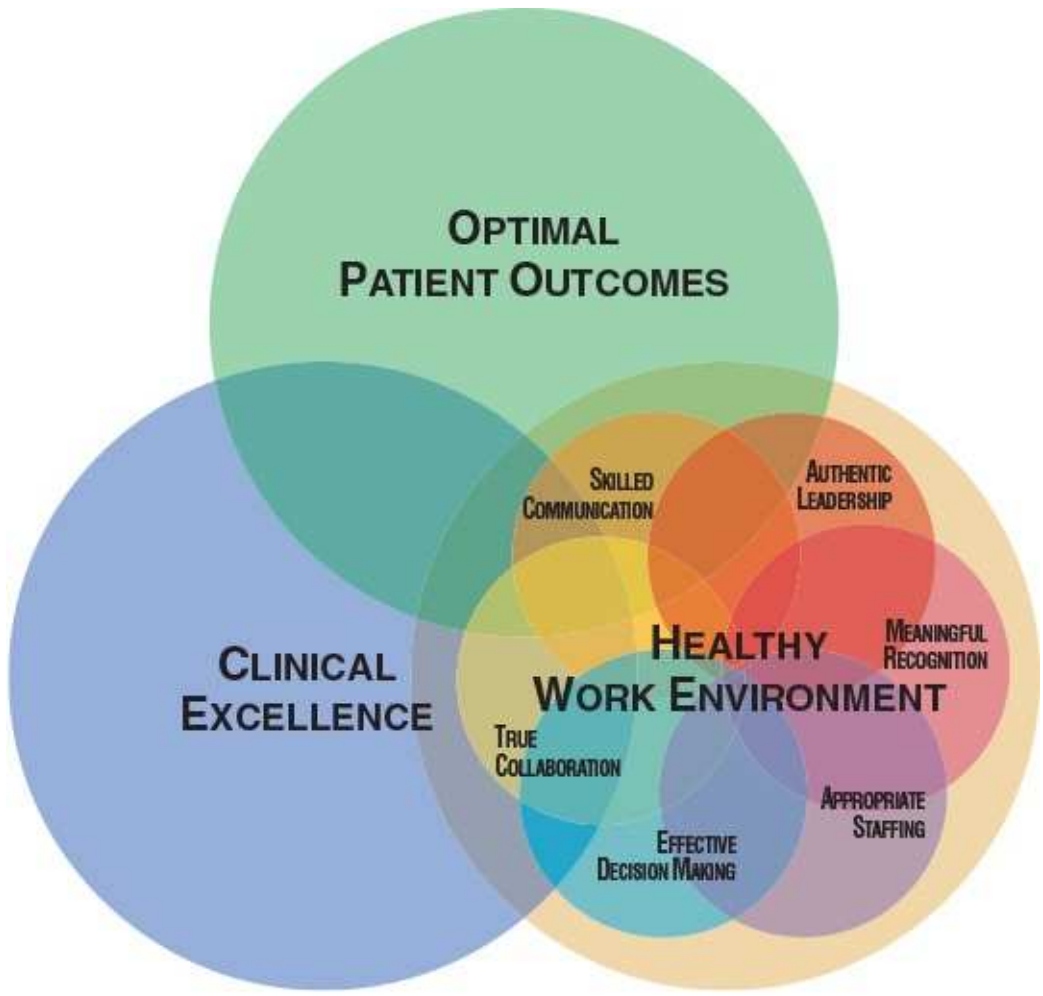
According to the study *Silence Kills: The Seven Crucial Conversations for Healthcare* (Maxfield et al., 2005), the prevalent culture of poor communication and collaboration among health professionals is significantly related to continued medical errors and staff turnover. Additionally, a lack of adequate support systems, skills, and personal accountability results in communication gaps that can cause harm to patients. Results of this national study of more than 1,700 health professionals, conducted by the American Association of Critical-Care Nurses (AACN) and VitalSmarts, include these facts:

- Up to 84% of health care providers and 62% of nurses and other clinical care providers have seen coworkers taking shortcuts that could be dangerous to patients.
- Up to 88% of health care providers and 48% of nurses and other providers work with people who show poor clinical judgment.
- Fewer than 10% of health care providers, nurses, and other clinical staff directly confront their colleagues about their concerns, and one in five health care providers said they have seen harm come to patients as a result.
- The 10% of health care workers who raise these crucial concerns observe better patient outcomes, work harder, and are more satisfied and more committed to staying in their jobs.

The study pinpoints seven categories of common communication problems that are rarely addressed. See Table 19-3

for examples of the seven crucial conversations in health care that nurses and other professionals must learn to master. If you find yourself in one of these situations, ask an experienced and trusted colleague how best to respond, and don't accept an answer such as "Spare yourself some grief and do nothing."

Table 19-3 The Seven Crucial Conversations in Health Care



CATEGORY OF CONVERSATION	EXAMPLES	RECOMMENDATIONS
1. Broken rules	Colleague fails to wash hands.	Confront your colleague and tell her that you noticed that she failed to wash her hands and that this could be harmful to herself, the patient, or other patients. If the behavior continues, report your concerns to the nurse manager and work up the chain of command.
2. Mistakes	Nurse administers medication to the wrong patient and asks you to keep an eye on the patient for adverse reactions. She does not plan to report the error.	Tell your colleague that you'll be happy to help watch the patient but that a full report needs to be made. If appropriate, help your colleague identify what contributed to her giving the medication to the wrong patient.
3. Lack of support	Nurse refuses to help a colleague move an obese patient although she has time to do so.	Explain to this nurse that teamwork is essential to good outcomes and that her behavior is simply unacceptable. "When we have patients with special needs and need all hands on deck, everyone who's free is obligated to help out!" Develop and enforce zero tolerance for selfish behavior.
4. Incompetence	Nurse fails to correctly administer dialysis. She wasn't finished with her orientation to the unit and attempted a procedure before she was prepared to do it solo.	In addition to reporting the error, help the nurse identify that overconfidence in their abilities can have deadly results for patients. The nurse manager will need to address the incompetence.
5. Poor teamwork	A particularly difficult family is splitting the team by choosing (and rewarding) favorites among the staff and complaining to them about other workers. The staff is encouraging this behavior.	Someone needs to call the team together and name the divisive behavior and get everyone working together again. If there is staff who are problematic, appropriate channels need to be used to address these behaviors.
6. Disrespect	When a student nurse asks a physician if she has time to answer a few questions for her patient, the physician screams at her and tells her that she has more important things to do than babysit her patient and tells the student to find someone else to answer the questions.	The student should calmly tell the physician that her response is inappropriate and that she is entitled to respectful conversation, then seek the counsel of an experienced nurse. The physician's behavior should be reported.
7. Micromanagement	A student asks her clinical preceptor, "Will you walk me through this procedure before I do it, since it's my first time?" The preceptor then takes over, doing the procedure for the student, and starts watching her every move.	The student should inform her preceptor that she merely wanted to review the steps of the procedure to make sure that she would perform it correctly and that it is essential for the student to gain experience by trying new procedures. If the preceptor's behavior does not change, the student should seek the counsel of her instructor.

Box 19-4 **The American Association of Critical-Care Nurses Standards for Establishing and Sustaining Healthy Work Environments**

- **Skilled communication.** Nurses must be as proficient in communication skills as they are in clinical skills.
- **True collaboration.** Nurses must be relentless in pursuing and fostering true collaboration.
- **Effective decision making.** Nurses must be valued and committed partners in making policy, directing and evaluating clinical care, and leading organizational operations.
- **Appropriate staffing.** Staffing must ensure the effective match between patient needs and nurse competencies.
- **Meaningful recognition.** Nurses must be recognized and must recognize others for the value each brings to the work of the organization.
- **Authentic leadership.** Nurse leaders must fully embrace the imperativeness of a healthy work environment, authentically live it, and engage others in its achievement.

Interdependence of a healthy work environment, clinical excellence, and optimal patient outcomes.

Interdependence of a healthy work environment, clinical excellence, and optimal patient outcomes.

Source: Used with permission from American Association of Critical-Care Nurses (AACN). (2005). AACN standards for Establishing and Sustaining Healthy Work Environments: A Journey to Excellence. American Journal of Critical Care, *14*(3), 187–197. Author.

A follow-up to this study, conducted by VitalSmarts, AACN, and the Association of periOperative Registered Nurses (AORN), revealed that safety tools fail to address a second category of communication breakdowns: "undiscussables." These are risks that are widely known but not discussed: dangerous shortcuts, incompetence, and disrespect (Maxfield et al., 2010). This study revealed that too many nurses are in situations in which they feel it is unsafe to speak up about problems or are unable to get others to listen.

AACN's commitment *to actively promote the creation of healthy work environments that support and foster excellence in patient care* is a superb example of nursing leadership. See Box 19-4 for AACN's six essential standards for establishing and sustaining healthy work environments. The standards represent *evidence-based* and *relationship-centered* principles of professional performance. Each standard is considered essential, because studies show that effective and sustainable outcomes do not emerge when any standard is considered optional. For copies of the *Silence Kills* report and the AACN Standards for Establishing and Sustaining Healthy Work Environments, visit https://www.aacn.org/nursing-excellence/healthy-work-environments/~/media/aacn-website/nursing-excellence/healthy-work-environment/silencekills.pdf?la=en or https://www.aacn.org/nursing-excellence/standards/aacn-standards-for-

establishing-and-sustaining-healthy-work-environments.

In 2015, AACN conducted a public forum campaign to identify aspects of nurses' work environments inhibiting optimal patient care.

Nurse Self-Care Alert

The barriers to practice assessment identified five main themes contributing to workplace stressors: (1) staff shortages and higher workloads; (2) government regulations and hospital requirements; (3) disrespectful behaviors and unrealistic expectations of patients and their families; (4) lack of authentic leadership within practice environments; and (5) hostile workplace culture. These stressors are known to compromise nurses' job satisfaction and engagement, increase role conflict, lead to friction with leadership, and promote poor relationships between coworkers (Grant et al., 2020).

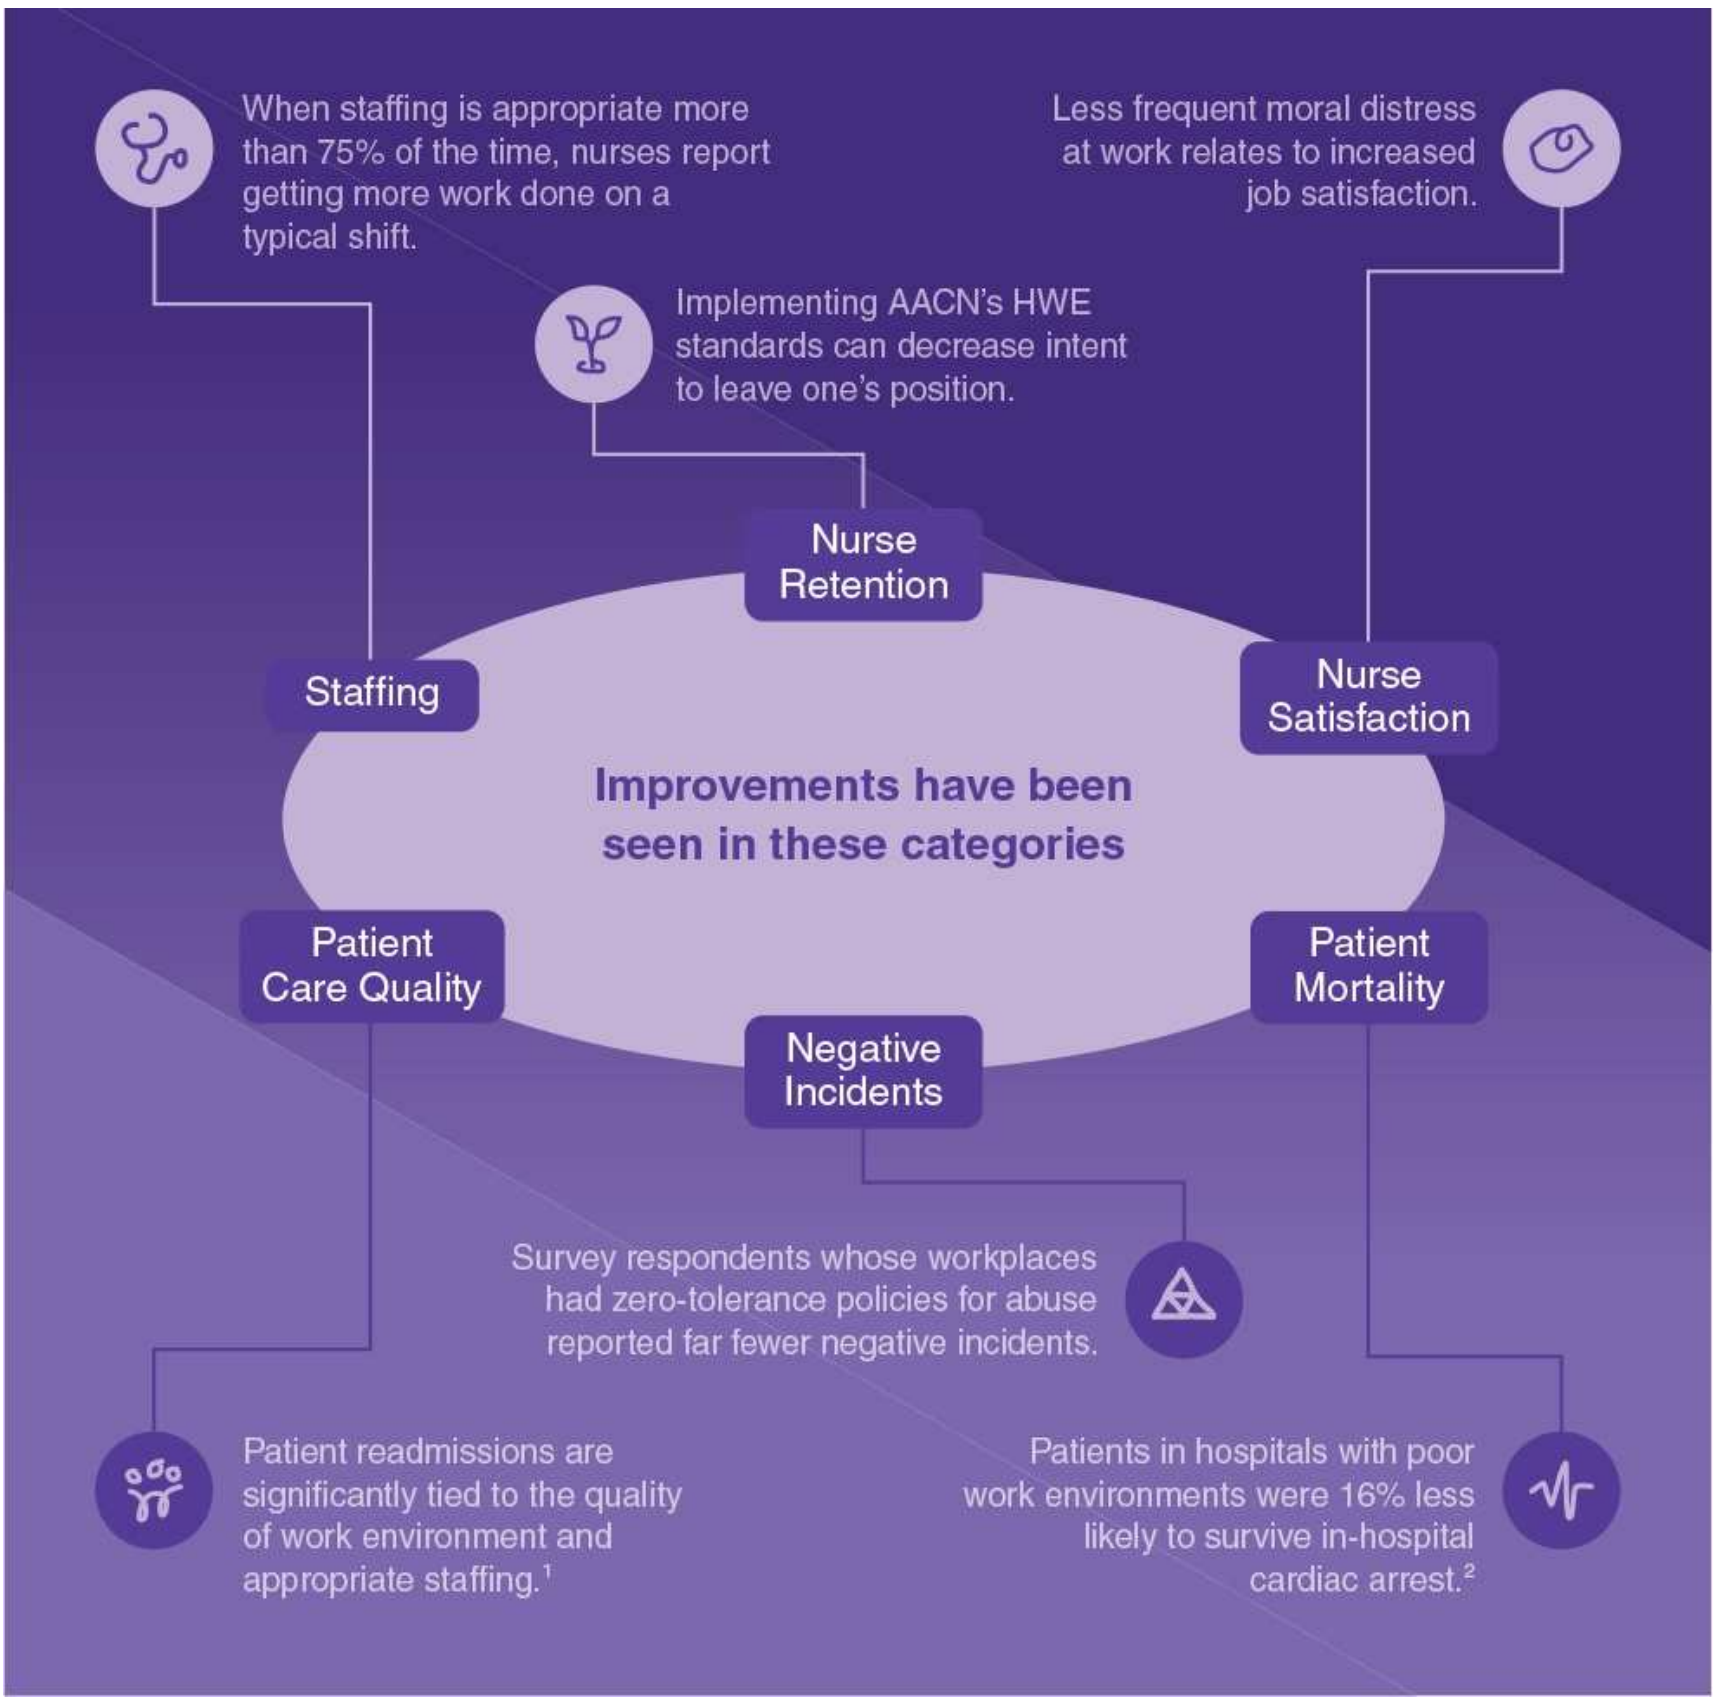

FIGURE 19-2. Implementing standards works. A healthy work environment (HWE) can affect everything in your unit, from nurse engagement and retention to patient outcomes. AACN's Critical Care Nurse Work Environment shows that nurse work environments have improved, but there's still a lot of work to be done. (*Source:* Used with permission from American Association of Critical-Care Nurses [AACN] [2020]. *AACN healthy work environments*. https://www.aacn.org/nursing-excellence/healthy-work-environments)

Nurses who are committed to thoughtful, patient-centered care will want to pay careful attention to these known barriers to quality care.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

In February 2019, AACN released the results of "Critical Care Nurse Work Environments 2018: Findings and implications (Ulrich et al., 2019). Figure 19-2 clearly demonstrates the difference implementing the health work environments makes. You will want to pay attention in your different clinical rotations to the presence or absence of these standards in your different work cultures.

Evaluative Programs

In the United States, regulatory facilities such as State Boards of Nursing, the Joint Commission, and the Professional Standards Review Organization, along with the National Health Planning and Resources Development Act of 1975, require nurses to document that nursing standards are being implemented and maintained. Each of these facilities is concerned with quality care and quality control. The decreased availability of resources to treat patients in hospitals and the unavailability of sufficient alternative treatment settings pose a strong challenge to the nursing profession to find ways to avoid compromising quality of care. Numerous professional organizations are working to meet this challenge. Selected web resources for patients and families can be found on their websites.

Quality Assurance

Quality-assurance programs are special programs that promote excellence in nursing. These range from small programs conducted by nurses on a nursing unit to those developed for an entire institution, state, or country.

Quality-assurance programs enable nursing to be accountable to society for the quality of nursing care. Such programs also respond to the public mandate for professional accountability. They help ensure survival of the profession, encourage nursing's fidelity to its moral and ethical responsibilities, and assist nursing to comply with other external pressures.

There are two different approaches to ensuring quality. *Quality by inspection* focuses on finding deficient workers and removing them. However, nurses and others working in a setting using this approach may be afraid to admit a mistake or error and wrongly attempt to hide a problem. Such behavior is never acceptable and may result in serious harm to patients. *Quality as opportunity,* on the other hand, focuses on finding opportunities for improvement and fosters an environment that thrives on teamwork, with people sharing the skills and lessons they have learned. Mistakes are viewed as a result of a problem in the system rather than due to a lack of motivation or lack of effort by a particular worker. In work environments using this approach, nurses respond with openness and a desire to learn because their integrity and self-worth are not threatened. Our outcome should be to work in an environment in which quality measurements encourage our best efforts.

In 1975, the ANA developed a model quality-assurance program consisting of seven steps:

. Identify values.
. Identify structure, process, and outcome standards and criteria.
. Measure the degree of attainment of criteria and standards.
. Make interpretations about strengths and weaknesses based on such measurements.
. Identify possible courses of action.
. Choose a course of action.
. Take action.

The ANA hoped the model would be used to develop and implement quality-assurance programs within institutions.

The ANA model directs attention to three essential components of quality care: structure, process, and outcome. Other types of quality-assurance programs may focus only on one of these components or on a mixture of components.

- A **structure evaluation** or audit focuses on the environment in which care is provided. Standards describe physical facilities and equipment; organizational characteristics, policies, and procedures; fiscal resources; and personnel resources.
- The focus of a **process evaluation** is the nature and sequence of activities carried out by nurses implementing the nursing process. Criteria make explicit acceptable levels of performance for nursing actions related to patient assessment, diagnosis, planning, implementation, and evaluation.
- **Outcome evaluation** focuses on measurable changes in the health status of the patient, or the end results of nursing care. While the proper environment for care and the right nursing actions are important aspects of quality care, the critical element in evaluating care is demonstrable changes in patient health status.

Concept Mastery Alert

It is important to distinguish the different types of evaluation in quality assurance. A helpful way to remember the different types is to focus on the meaning of the word. For example, *structure* implies buildings or facilities; *process* implies action or activities; *outcome* implies changes in health.

From Quality Assurance to Quality Improvement

Concerns about the spiraling costs of health care, coupled with the success of industrial models for QI, led to a strong commitment to QI in the 1990s. **Quality improvement (QI)**—also known as continuous quality improvement (CQI) or

total quality management (TQM)—consists of systematic and continuous actions that lead to measurable improvement in health care services and the health status of targeted patient groups. The U.S. Department of Health and Human Service, Health Resources and Services Administration (HRSA), identifies the four key principles of QI (HRSA, 2011):

- Focus on systems and processes
- Focus on patients
- Focus on being part of the team
- Focus on use of the data (Read about Quality Improvement in Chapter 2.)

From the patient's point of view, one of the most important outcomes of QI is the recognition that patient satisfaction in health care is as important as customer satisfaction in retail business. With increased competition for the health care dollar, providers are learning that it is important to offer services that patients value and to offer them in a way that is valued by patients. By reemphasizing the critical nature of nursing's *person* versus *task* orientation, QI underscores the need for nurses to blend cognitive, technical, interpersonal, and ethical/legal competencies successfully.

Patient Satisfaction

An evaluative program that focuses on patient satisfaction is a powerful tool for patients and families who want to know what care will be like before choosing a health care facility. Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS), the Centers for Medicare and Medicaid Services' patient satisfaction program, is the first national, standardized, publicly reported survey of patients' perspectives of hospital care. The program provides consumers with information about a hospital's performance in key areas of communication, pain control, timeliness of care, discharge instructions, hospital cleanliness, and treatment with courtesy and respect. The survey was designed to produce data about patients' perspectives of care that allow objective and meaningful comparisons of hospitals on topics that are important to consumers. Public reporting of the survey results creates new incentives for hospitals to improve quality of care. Public reporting also serves to enhance public accountability in health care by increasing the transparency of the quality of hospital care provided in return for the public investment.

Are you helping or hurting your hospital? With your first clinical rotation, you can ask yourself how you think your patients would respond if asked the following questions:

- During this hospital stay, how often did nurses treat you with courtesy and respect, listen carefully to you, and explain things in a way you could understand?
- During this hospital stay, after you pressed the call button, how often did you get help as soon as you wanted it?

You can see how your local hospitals compare by searching the website https://www.medicare.gov/hospitalcompare/search.html.

Nursing's Patient Safety and Quality Initiative

In March of 1994, the ANA Board of Directors launched a major multiphase initiative to investigate the impact of health care restructuring on the safety and quality of patient care as well as on nursing. Through its Patient Safety and Quality Initiative, the ANA highlighted the strong linkages between nursing actions and patient outcomes.

In 1998, the ANA funded the development of a national database to house **nursing-sensitive quality indicators**, which are indicators specific to nursing that identify structures of care and care processes that influence care outcome. Examples of nursing-sensitive quality indicators for acute care settings are the mix of RNs, LPNs, and unlicensed staff caring for patients, the total number of nursing care hours provided per patient day, and the rates of pressure injuries and patient falls. The goals of the **National Database of Nursing Quality Indicators (NDNQI)** are to promote and facilitate the standardization of information submitted by hospitals across the United States on nursing quality and patient outcomes.

The ANA Patient Safety and Quality Initiative has focused on educating RNs about quality measurement; informing the public and purchasing/regulating constituencies about safe, quality health care; and investigating research methods and data sources to empirically evaluate the safety and quality of patient care.

QSEN QUALITY IMPROVEMENT

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems. If you find something in your work setting that "isn't working," design a small test of change in daily work (using an experiential learning method such as Plan-Do-Study-Act) and use measures to evaluate the effect of change. Read more about Plan-Do-Study-Act in Chapter 2.

Concurrent versus Retrospective Evaluation

Nursing care and patient outcomes may be evaluated while the patient is receiving care (i.e., a concurrent evaluation) or after the patient has been discharged (i.e., a retrospective evaluation). **Concurrent evaluation** is conducted by using

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

direct observation of nursing care, patient interviews, and chart review to determine whether the specified evaluative criteria are met. **Retrospective evaluation** may use postdischarge questionnaires, patient interviews (by telephone or face to face), or chart review (nursing audit) to collect data.

The type of retrospective audit most familiar to nurses working in hospitals is the Joint Commission retrospective chart review. This accrediting body initially required hospitals to conduct a certain number of audits per year.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in evaluating the plan of care, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

- How effectively did you engage your patients and families in evaluating the plan of care? To what degree does patient/family satisfaction motivate your efforts to provide high-quality, safe care?
- What value do you attach to monitoring the patient's achievement of expected outcomes? In what ways did this monitoring result in valuable changes to the plan of care?
- Did your experience with evaluation reveal the need for changes in yourself or in your practice setting? How might these be accomplished?

The cultivation of evaluation as a critical component of the nursing process helps ensure nursing's continued success in achieving desired changes in patient health status. Nursing actions are far too valuable and costly to be haphazardly implemented. Evaluation that is carefully planned and executed can direct and redirect these actions to maximize the patient's benefit. This is the outcome and challenge of nursing evaluation.

Perhaps the most important questions to reflect on are: Are your patients and families/caregivers better for having had *you* share in the critical responsibility of partnering with them to evaluate the development and implementation of the plan of care? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Interview five students who have personal fitness goals. Ask them to describe what personal factors have helped or hindered them in achieving their goals. Note commonalities and differences. Reflect on how you can help patients tap their own personal strengths to achieve their outcomes more successfully.

. Interview several patients and ask them what qualities in a nurse are most helpful as they try to achieve their health outcomes. Similarly, ask what nurse qualities are most problematic. Reflect on how you measure up in terms of both positive and negative nurse qualities.

. Interview three or more experienced nurses in the same practice setting. Ask them what system variables (such as philosophy of care, nurse-to-patient ratio, professional and nonprofessional staff mix, nursing management, adequacy of resources) most influence their ability to deliver quality care. Identify variables you want to look for when you interview for a job.

. Specify how nurses might use the AACN standards and crucial conversation recommendations to change the outcomes in the following situations:

- A nurse knows that a patient's pain medication isn't working but decides not to call his attending health care provider, because the health care provider was verbally abusive to her in the past and believes his patients "don't need analgesics."
- A new policy was developed to make sure that obese patients are transferred safely without harm to themselves or staff. The nurse manager places the new policy in the policy manual but fails to educate staff in the new bariatric unit. Moreover, some nurses have been quite vocal about not putting themselves at risk with these patients and have refused to participate in collaborative efforts to move these patients safely.
- Two nurses call in sick, and staffing is at an all-time low. Additional patients are added to each nurse's assignment, increasing the probability that errors will be made. The nurses are frustrated and angry.

PRACTICING FOR NCLEX

. A university student works with the student health nurse to develop a weight loss plan that includes increasing activity and avoiding empty calories. At the next session, the student has lost 1 lb instead of the projected 5 lb. What action will the nurse take next?

a. Congratulate the student and continue the care plan
b. Terminate the care plan since it is not working
c. Give the student more time to reach the targeted outcome
d. Modify the plan after discussing possible reasons for partial success

. A visiting nurse is following up with a patient who was given a prescription for a diuretic and told to chart her weight daily. The patient's weight has increased 5 lb since the nurse's last visit. What actions will the nurse take first?

a. Explain to the patient that it is clear she is not adhering to her prescription and the health care provider will be notified
b. Document the 5-lb weight gain and ask the patient about sodium intake and medication side effects
c. Terminate the plan of care while determining the cause for the weight gain
d. Encourage the patient to continue the prescription and return in 1 week

. During orientation to the critical care unit, a nurse learns that staff follow existing clinical practice guidelines, also called standards, for patient care. Which activities does the nurse expect to be included in these guidelines? Select all that apply.

a. Monitoring vital signs and pulse oximetry every hour
b. Using intuition to troubleshoot patient problems
c. Repositioning a patient on bed rest every 2 hours
d. Becoming a nurse mentor to a student nurse
e. Administering pain medication prescribed by the health care provider
f. Becoming involved in community nursing events

. After reviewing the admission SBAR and plan of care, the nurse begins to evaluate patient outcomes. Which statement reflects a clear evaluation of the patient's primary problem?

Electronic health record (EHR)
8:00 AM Admission note
S. Patient with profound wheezing, tachycardia, and anxiety
B. Patient has history of asthma, for which she regularly uses inhalers and carries a rescue inhaler
A. Pulse oximetry 89%, cyanosis of lips, dyspnea with increased work of breathing
R. Admit to telemetry unit, add IV corticosteroids and mini-nebulizer treatments

a. The patient states they were terrified when they were fighting to breathe and the wheezing would not stop.
b. The nurse determines the patient's strengths include adherence to their medication regimen.
c. The care plan includes the health problem of impaired gas exchange, etiology, bronchospasm.
d. At 10:00 AM, no wheezing on auscultation, pulse oximetry is 94%, the patient reports no anxiety; the outcome has been met.

. A nurse is writing nursing outcomes in the affective domain for a patient who is trying to stop smoking. Which outcome statement will the nurse include in the care plan?

a. "The patient will state the relationship between smoking and coronary artery disease."
b. "After the teaching session, the patient will redemonstrate the proper application of a nicotine patch."
c. "The patient will state they value a healthy body sufficiently to stop smoking prior to discharge."
d. "The patient will state that any changes in cough should be reported to the health care provider"

. A nurse writes the outcome for a patient who is trying to lose weight: "The patient will explain the relationship between weight loss, increased exercise, and decreased calorie intake." This outcome reflects which domain of learning?

a. Cognitive
b. Psychomotor
c. Affective
d. Physical changes

. A nurse is writing an evaluative statement for a patient who is trying to lower cholesterol through diet and exercise. Which evaluative statement is most correctly written?

a. "Outcome met."
b. "1/21/25—Patient reports no change in diet."
c. "Outcome not met. Patient reports no change in diet or activity level."
d. "1/21/25—Outcome met. Cholesterol level has decreased 10 mg."

. A nurse is attempting to improve care on the pediatric unit of a hospital. Which improvements might the nurse employ when following the recommendations of the Institute of Medicine's Committee on Quality of Health Care in America? Select all that apply.

a. Basing patient care on continuous healing relationships
b. Customizing care to reflect the competencies of the staff
c. Using evidence-based decision making
d. Having a charge nurse as the source of control

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

e. Using safety as a system priority
f. Recognizing the need for secrecy to protect patient privacy

. As part of a hospital-wide quality-assurance program, an electronic medical record review for the last 6 months reveals a higher incidence of falls on a specific unit. The nurse authoring the study refers to the review as what type of evaluation?

a. Quality by inspection
b. Retrospective evaluation
c. Concurrent study
d. Quality by indicator

. The nurse manager of a unit with an excellent safety record meets with staff to present the findings of a recent audit. The manager states, "We're doing well, but I believe we can do better. Who's got an idea to foster increased patient well-being and satisfaction?" This leader has demonstrated they value which process?

a. Quality assurance
b. Quality improvement
c. Process evaluation
d. Outcome evaluation

. Nurses note that allowing patients to choose the time of their breakfast to improve patient satisfaction has resulted in medication delays for patients who have prescriptions for medications taken on an empty stomach. Which action will direct the nurses to the best outcome?

a. Asking the pharmacy to dispense the medication at bedtime
b. Suggesting a quality improvement project piloting a 6:00 AM administration
c. Requesting that the health care provider prescribe the medication for midnight
d. Telling the nurse manager that patients are getting their medications late

. The nurse on a medical-surgical unit attends a class on the seven crucial conversations in health care. After observing a colleague administer an incorrect dose of medication without reporting it, which action will the nurse take?

a. Speak to the nurse privately and tell her if she does not complete an event report, you will report her to the unit manager
b. Tell the nurse you overheard her discussing giving too much medication, and she must complete an event report or you will
c. Explain that you are aware of the medication incident, and you can assist her in notifying the health care provider for patient safety
d. Give the nurse a copy of the handout from the class and explain that this class in crucial conversations was very helpful

. A nurse is using the classic elements of evaluation when caring for patients. Place the steps of evaluation in the proper order they are carried out.

a. Interpreting and summarizing findings
b. Collecting data to determine whether evaluative criteria and standards are met
c. Documenting your judgment
d. Terminating, continuing, or modifying the plan
e. Identifying evaluative criteria and standards (i.e., expected patient outcomes)

. The care plan for a patient just diagnosed with diabetes contains the expected outcome: "the patient will correctly measure the insulin dose and self-administer the injection, using correct technique by 12/12/24." The nurse observes the client fumbled with the syringe and drew up less insulin than prescribed. What action will the nurse take first?

a. Document that the plan of care was unsuccessful
b. State continuation of the care plan is indicated
c. Assess the patient's vision and dexterity and revise the plan
d. Designate a family member to administer the insulin

ANSWERS WITH RATIONALES

. **d.** Since the student has only partially met her outcome, the nurse should first explore the factors making it difficult for her to reach her outcome and then modify the care plan. As the plan is not completely working as written, continuing without further assessment is contraindicated. It is premature to terminate the care plan before the outcome is met. The student may need additional support and time to reach the outcome.

. **b.** The nurse documents the goal has not yet been achieved and also suspects the patient has not adhered to the prescription, perhaps due to frequent urination or other side effects. The nurse further assesses the patient's

understanding of the medication's purpose and effects, understanding of the disease process and complications.

- **a, c, e.** Standards are the levels of performance accepted and expected by the nursing staff or other health care team members. They are established by authority, custom, or consent. Standards would include monitoring patient status every hour, repositioning a patient on bed rest every 2 hours, and administering pain medication prescribed by the health care provider. Using intuition to troubleshoot patient problems, becoming a nurse mentor to a student nurse, and becoming involved in community nursing events are not included in patient care standards.
- **d.** The two-part evaluative statement includes a decision about how well the outcome was met, along with patient data or behaviors that support this decision. Outcomes may have been met, partially met, or not met. The nurse collects evaluative data to measure outcome achievement. While this may justify terminating the care plan, that is not necessarily so. Data to assess health problems and patient variables are collected during the first step of the nursing process.
- **c.** Affective outcomes pertain to changes in patient values, beliefs, and attitudes. Cognitive outcomes involve increases in patient knowledge; psychomotor outcomes describe the patient's achievement of new skills; physical changes are actual bodily changes in the patient (e.g., weight loss, increased muscle tone).
- **a.** Cognitive outcomes involve increases in patient knowledge; psychomotor outcomes describe the patient's achievement of new skills; affective outcomes pertain to changes in patient values, beliefs, and attitudes; and physical changes are actual bodily changes in the patient (e.g., weight loss, increased muscle tone).
- **d.** The evaluative statement should contain a date; the words "outcome met," "outcome partially met," or "outcome not met"; and the patient data or behaviors that support this decision. The other answer choices are incomplete statements.
- **a, c, e.** Care should be based on continuous healing relationships and evidence-based decision making. Customization should be based on patient needs and values with the patient as the source of control. Safety should be used as a system priority, and the need for confidentiality of care with transparency for the patient and designated individuals, rather than secrecy is used.
- **b.** Quality by inspection focuses on finding deficient workers and removing them. Concurrent evaluation uses direct observation of nursing care, patient interviews, and chart review to determine whether the specified evaluative criteria are met. Retrospective evaluation may use post discharge questionnaires, patient interviews (by telephone or face to face), or chart review (nursing audit) to collect data. Quality as opportunity focuses on finding opportunities for improvement and fosters an environment thriving on teamwork, with people sharing the skills and lessons they have learned.
- **b.** Unlike quality assurance, quality improvement (QI) is internally driven. QI focuses on patient care rather than organizational structure and processes rather than people, and has no end points. Its goal is improving quality rather than assuring quality. Process evaluation and outcome evaluation are types of quality-assurance programs.
- **b**. Quality improvement or continuous quality improvement involves systematic, continuous actions that lead to measurable improvement in health care services and the health status of targeted patient groups. Quality-assurance programs enable nursing to be accountable for the quality of nursing care. Making changes without gathering needed data may prove unsafe or a waste of time. Reporting to the nurse manager does not reflect professional commitment to improving processes.
- **c.** *Crucial Conversations for Healthcare,* addresses "undiscussable" communication breakdowns and gaps that can result in patient harm, medical errors, and staff turnover. When nurses feel unsafe to report problems or are not heard, dangerous shortcuts, incompetence, and disrespect may ensue. Threatening the nurse with reporting them is unprofessional and inconsistent with the crucial conversations. Providing a handout is passive aggressive and does not clearly relate the medication error to this concept.
- **e, b, a, c, d.** The five classic elements of evaluation in order are (1) identifying evaluative criteria and standards (what the nurse looks for during evaluation, that is, expected patient outcomes); (2) collecting data to determine whether these criteria and standards are met; (3) interpreting and summarizing findings; (4) documenting your judgment; and (5) terminating, continuing, or modifying the plan.
- **c.** When an outcome is not achieved, the nurse can (1) delete or modify a diagnosis; (2) revise the diagnosis, making it more realistic; (3) adjust the time criteria, or (4) modify the nursing interventions. This outcome was not successfully met; further assessment and revision is indicated. It is inappropriate for the nurse to designate a family member to take over insulin administration without additional assessment and patient permission.

Documenting and Reporting

Phillippe Baron

Phillippe is a 52-year-old man being discharged from the outpatient surgery department after undergoing a colonoscopy for removal of three polyps. He will be going home with his wife, who is a nurse, and they both require discharge teaching.

Millie Delong

Millie, a 44-year-old woman, develops a wound infection following abdominal surgery. Wound care with normal saline irrigations is ordered four times a day.

Jason Chandler

Jason, 15 years old and in police custody, is brought to the emergency department for treatment because he allegedly consumed a latex bag containing a handful of pieces of crack cocaine to avoid arrest. Treatment with insertion of nasogastric tube and bowel preparation solution is ordered. Jason is refusing treatment because he denies possession of drugs entirely.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Use standard professional guidelines for effective nursing documentation.
. Identify measures to protect confidential patient information.
. Identify approved abbreviations and symbols used for documentation and distinguish these from error-prone abbreviations and symbols.
. Describe the purposes of different types of patient health records.
. Compare and contrast different methods of documentation, including electronic health records, source-oriented records, problem-oriented medical records, PIE charting, focus charting, charting by exception, and the case management model.
. Describe the purpose and correct use of each of the following formats for nursing documentation: nursing assessment, nursing care plan, critical/collaborative pathways, progress notes, flow sheets, discharge summary, and home care documentation.
. Recognize that documentation by the nurse should be complete, accurate, current, and concise because the patient health record is a legal document.
. Describe the nurse's role in communicating with other health care professionals by reporting.

Effective communication among health care professionals is essential to the coordination and continuity of thoughtful person-centered care. Communicating effectively enables personnel to support and complement one another's services and to avoid duplications and omissions in care. This chapter describes two methods of communication central to nurses' professional role: documenting and reporting. The first day you care for patients, you will find yourself conferring with colleagues, recording your interventions, and reporting on your patient's progress toward valued goals and outcomes. As you develop these skills, you will see a link between communicating information and clinical reasoning and clinical judgment. As you document data, you are looking for relationships and patterns—things that might otherwise be overlooked. As you confer with the patient and the patient's family and professional caregivers, you may learn something about the patient or situation that enhances your data set and clarifies the patient's health problem and related need for care (see the Reflective Practice box for an example). This chapter will help you assume communication responsibilities with confidence and skill. The communication process itself and specific communication techniques are discussed in Chapter 8.

DOCUMENTING CARE

Documentation is the written or electronic legal record of all pertinent interactions with the patient: assessing, diagnosing, planning, implementing, and evaluating. You can expect to repeatedly hear "If it wasn't charted, it wasn't done" from your clinical instructors. Today, increasingly sophisticated management information systems help manage patient-specific data and information. These records contain data used to facilitate quality, evidence-based patient care, serve as financial and legal records, help in clinical research, and support decision analysis. Information specialists aim to create an environment that supports timely, accurate, secure, and confidential recording and use of patient-specific information.

The **patient record** is a compilation of a patient's health information (PHI). Each health care institution or facility has policies that specify the nurse's documentation responsibilities. The Joint Commission specifies that nursing care data related to patient assessments, nursing diagnoses or patient needs, nursing interventions, and patient outcomes are permanently integrated into the patient record. Each nurse is expected to practice according to local policies and professional standards.

Guidelines for Effective Documentation

The patient record is the only permanent legal document that details the nurse's interactions with the patient. It is the nurse's best defense if a patient or patient surrogate alleges nursing negligence. Unfortunately, there are often omissions in the nursing documentation, along with repetitious or inaccurate entries. Although these errors might go undetected and have no effect on the patient, they might also seriously affect the care the patient receives, undermine nursing's credibility as a professional discipline, and cause legal problems for the nurses involved. Adherence to the documentation guidelines shown in Box 20-1 (on page 521) helps to prevent errors. Be sure to also check the guidelines later in this chapter for electronic documentation.

Responding to the widespread nursing concern that the time spent documenting nursing care comes at the expense of providing safe, quality patient care, the American Nurses Association (ANA) introduced a tool to streamline the nursing documentation process in 2003 and revised the tool in 2010. Available as a brochure entitled ANA's Principles for Nursing Documentation: Guidance for Registered Nurses, this guide includes policy statements, principles, and recommendations to assist nurses with documentation and to comply with institutional and regulatory requirements.

The policy statements and principles outlined in the guide are based on the ANA Code of Ethics for Nurses *w*ith Interpretive Statements (ANA, 2015a) and Scope and Standards of Practice (ANA, 2021). In addition, the formulated principles in many instances are based on standards set forth by state and federal regulatory facilities and the Centers for Medicare & Medicaid Services (CMS), and through accrediting organizations, such as the Joint Commission and the National Committee for Quality Assurance (NCQA). The 2010 ANA Standards identify the following characteristics of effective documentation: accessible; accurate, relevant, and consistent; auditable; clear, concise, and complete; legible/readable (particularly in terms of the resolution and related qualities of EHR content as it is displayed on the screens of various devices); thoughtful; timely, contemporaneous, and sequential; reflective of the nursing process; and retrievable on a permanent basis in a nursing-specific manner (ANA, 2010, p. 12). Note that revised standards may be available after this text goes to publication.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

Working in the emergency department (ED) this summer never ceased to amaze me. Police brought Jason Chandler to the ED, a 15-year-old male who was in custody for drug charges. Apparently, as police approached Jason, he consumed a latex bag containing a handful of pieces of crack cocaine to avoid arrest. He was brought to the ED as a precaution. If the bag broke inside his gastrointestinal tract, it would have toxic consequences. Jason was refusing treatment because he denied the possession of drugs entirely. The ED attending health care provider was unsure of his legal rights for treating the boy and called the hospital attorney. The attorney said the physician could force treatment if there were probable signs that ingestion had occurred. However, the boy was not showing any clinical manifestations of chemical ingestion. This was a dilemma because if the drugs leached into the boy's gastrointestinal tract, the health care provider stated that he most likely would not survive. The legal issue was whether the officer's statement of witnessing the ingestion was enough to constitute the need for treatment. The physician was about to begin treating the patient when his mother arrived, threatening to sue anyone and everyone who "touched her little boy."

My preceptor and I were assigned to this patient and were given orders to insert a nasogastric (NG) tube so that a bowel preparation solution (GoLYTELY) could be used to flush out the drugs. The hospital attorney concluded that there was probable cause to justify forced treatment. However, the mother was furious and said she would bring legal action under these circumstances, despite what the doctor or attorney said. As we entered the room to insert the NG tube and begin treatment, the boy, who was handcuffed to the bed, was screaming at us not to touch him.

Thinking Outside the Box: Possible Courses of Action

- Go with my preceptor and assist with the NG tube insertion.
- Refuse to treat the patient for fear of becoming part of a lawsuit.
- Allow my preceptor to sedate the patient against his will, to make the NG tube insertion easier.
- Inform the health care provider that I do not feel comfortable proceeding with treatment on a patient who refuses it and shows no clinical manifestations of drug toxicity.

Evaluating a Good Outcome: How Do I Define Success?

- The patient is benefited or, at the very least, not harmed by our actions.
- The hospital and its employees act in a legally defensible manner and are not sued by the patient's family.
- The patient accepts treatment.
- The mother is able to realize the need for medical intervention.
- Hospital policy is maintained.
- I learn more about our legal and ethical responsibilities.

Personal Learning: Here's to the Future!

My preceptor and I went into the room and explained to the patient and his mother the procedure of NG tube insertion and what the bowel preparation solution was expected to do. I think the mother appreciated that we were not talking to them in a condescending fashion and, therefore, began to see us as trying to help her son, not harm him. She asked a couple of questions about side effects of the medication and how the NG tube worked. She began to show signs of calming down until the health care provider walked into the room. Then she started to show her frustration again. Therefore, my preceptor politely asked the provider to leave. Subsequently, we were able to insert the NG tube, despite some resistance from the patient. Several hours later, the patient passed a package of crack rocks intact.

Obviously, this situation was very new to me. I had never dealt with a patient who was threatening to sue and who was clearly upset by what was happening. I was able to see the collaboration between the attending health care provider, the toxicologist, the hospital attorney, and the nurses and myself. This was an interesting case because the treatments were clearly necessary for the patient's well-being, but everyone wanted to make sure they were legally able to impose treatment. I learned that a hospital attorney is a good resource when legal questions or ambiguous situations arise.

I think that my professional legal skills need a fair amount of work. Unfortunately, I also believe that nurses violate the law more often than is recognized—for example, subtle breaches of the law such as failure to ensure patient safety and failure to follow facility policy. Although I feel that I understand many of the obvious legal violations, I think I have a lot to learn regarding legal issues in the nursing practice.

Julia Strobel, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your competencies for professional practice? Can you think of other ways to respond? What legal and ethical principles were involved in this situation? Which ones had the potential to be violated? Why was the clinical instructor more successful than the health care provider? Did the preceptor and nursing student ensure the patient's rights? How might this situation have been different if the patient were over 18 years of age? What knowledge, skills, and attitudes do you need to develop to continuously improve the quality and safety of care for patients like Jason?

Patient-Centered Care: How can you establish a successful partnership with a patient and family refusing treatment?

Teamwork and Collaboration/Quality Improvement: What role did the hospital attorney play? What other team members would be helpful? What needs to change to improve quality in this setting?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Jason? What safety needs does he have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Jason's record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Privacy and Confidentiality

Nurses and other professional caregivers learn and communicate private information about patients and their families every day.

What Information Is Confidential?

All information about patients is considered private or confidential, whether written on a paper, saved on a computer, or spoken aloud. This includes patient names and all identifiers such as address, telephone and fax number, Social Security number, and any other personal information. It also includes the reason the patient is sick or in the hospital, office, or clinic; the assessments and treatments the patient receives; and information about past health conditions. Protected health information might be found in the patient medical record, computer systems, telephone calls, voice mails, fax transmissions, e-mails that contain patient information, and conversations about patients among clinical staff.

While most nurses are staunch advocates of a patient's right to privacy and confidentiality, it is possible to violate these rights. For example, one nurse gives patient information over the phone to a patient's alleged spouse without knowing whether the patient wants the spouse to know; another talks about a difficult patient in the elevator; and another gives patient information to a professional caregiver who "knows" the patient but is not involved in the patient's care. Additional examples of breaches of confidentiality and security include the following:

- Discussing patient information in any public area
- Leaving patient medical information in a public area
- Leaving a computer unattended in an accessible area with medical record information unsecured
- Failing to log off a computer terminal
- Sharing or exposing passwords
- Copying or providing data, for yourself, coworkers, or any other party, except as required to fulfill job responsibilities
- Improperly accessing, reviewing, or releasing the record of a patient for whom one has no responsibility out of concern or curiosity, or requesting another person to do so
- Improperly accessing, reviewing, or releasing a patient record to use information in a personal relationship
- Improperly accessing, reviewing, or releasing the patient record of a public personality for the intent of giving or selling information to the media
- Improperly accessing, reviewing, or releasing confidential information of another member of the workforce who is also a patient
- Improperly accessing, reviewing, or releasing confidential information that may bring harm to the organization or people associated with it

Table 20-1 (on page 522) provides specific measures to use to ensure that information about your patients remains confidential.

Professional codes of ethics, facility policies, and state and federal privacy legislation dictate how patient information can be communicated (spoken verbally and in writing), where and how it can be stored, the appropriate people and entities to whom it may be divulged, and the purposes for which it may be divulged. Nurses must be familiar with these

guidelines.

Legal Alert

Take note! There have been reports of school suspensions for nursing and medical students who unprofessionally share patient experiences on social media platforms such as Facebook, Instagram, blogs, and YouTube. What may be an inadvertent or unintentional report of patient information may lead to your suspension or dismissal. Take the time to review the social media guidelines for nurses developed by the ANA National Student Nurses' Association and the National Council of State Boards of Nursing.

Box 20-1 **Documentation Guidelines**

Aim: Complete, accurate, concise, current, factual, and organized data communicated in a timely and confidential manner to facilitate care coordination and serve as a legal document.

Content

- Enter information in a complete, accurate, concise, current, and factual manner.
- Make sure your documentation reflects the nursing process and your professional responsibilities.
- Record patient findings (observations of behavior) rather than your interpretation of these findings.
- Avoid words such as "good," "average," "normal," or "sufficient," which may mean different things to different readers. It is best to document measurable, verifiable objective data.
- Avoid generalizations such as "seems comfortable today." A better entry would be "on a scale of 1 to 10, patient rates back pain 2 to 3 today as compared with 7 to 9 yesterday; vital signs returned to baseline."
- Note problems as they occur in an orderly, sequential manner; record the nursing intervention and the patient's response; update problems or delete as appropriate.
- Record precautions or preventive measures used.
- Document in a legally prudent manner. Know and adhere to professional standards and facility/institutional policy for documentation.
- Document the nursing response to questionable medical orders or treatment (or failure to treat). Factually record the date and time and the name of the health care provider who was notified of the concern and the exact health care provider response. If this occurs by phone, have a second nurse listen to the conversation and cosign the note. Verbal orders should always be documented as VO with the date, time, and name and credentials of the health care provider who gave the orders. If a nurse administrator was contacted, document the name of the administrator and date and time of contact. Documentation should give legal protection to the nurse, other caregivers, the health care facility or institution, and the patient.
- Document objectively. Avoid slang terms, stereotypes, or derogatory terms when charting. Document quotes from the patient and behaviors. Do not document your opinions or subjective feelings about a patient situation.
- Refrain from copying and pasting notes in an EHR, because the data may be outdated or inaccurate.

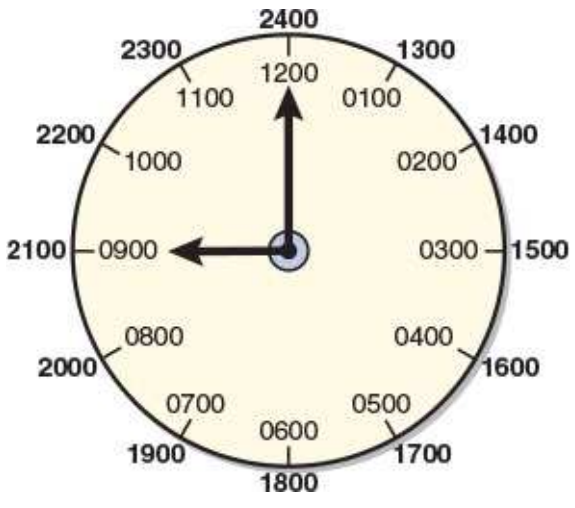
Timing

- Document in a timely manner. Follow facility policy regarding the frequency of documentation and modify this if changes in the patient's status warrant more frequent documentation.
- If you forget to document something, record it as soon as you can, following the procedures for making late entries. Example: Late entry: Patient reported passing gas at 8:00 AM this morning but no stool yet. Notified the surgical resident, Dr. Cotter—C. Taylor, RN.
- Indicate in each entry the date and both the time the entry was written and the time of pertinent observations and interventions. This is crucial when a case is being reconstructed for legal purposes.
- Most facilities use military time, one 24-hour time cycle, to avoid confusion between am and pm times (see accompanying figure).
- Document nursing interventions as closely as possible to the time of their execution. The more seriously ill the patient, the greater the need to keep documentation current. Never leave the unit for a break when caring for a seriously ill patient until all significant data are recorded.
- Never document interventions before carrying them out.
- Write a progress note for each of these instances:
  - Upon admission, transfer to another unit, and discharge

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- When a procedure is performed
- Upon receiving a patient postoperatively or postprocedure
- Upon communicating with health care providers regarding critical patient information (e.g., abnormal lab value result)
- For any change in patient status

Format



- Check to make sure you have the correct chart before writing.
- Record on the proper form or screen as designated by facility policy.
- With paper charts, print or write legibly in dark ink to ensure permanence. Use correct grammar and spelling. Use standard terminology, only commonly accepted terms and abbreviations, and symbols (see Box 20-3 on page 524). Alternatively, follow computer documentation guidelines.
- Date and time each entry.
- Record nursing interventions chronologically on consecutive lines. Never skip lines. Draw a single line through blank spaces.

Accountability

- Sign your first initial, last name, and title to each entry. Do not sign notes describing interventions not performed by you that you have no way of verifying.
- Do not use dittos, erasures, or correcting fluids. Draw a single line through an incorrect entry, and write the words “mistaken entry” or “error in charting” above or beside the entry and sign. Then rewrite the entry correctly.
- Identify each page of the record with the patient’s name and identification number.
- Recognize that the patient record is permanent. Follow facility policy pertaining to the color of ink and the type of pen or ink to be used. Ensure that the patient record is complete before sending it to medical records.

Confidentiality

- Patients have a moral and legal right to expect that the information contained in their patient health record will be kept private. Students should be familiar with facility policy and pertinent legislation about who has access to patient records other than the immediate caregiving team, and the process used to obtain access (see HIPAA guidelines).
- Most facilities allow students access to patient records for educational purposes. Students using patient records are bound professionally and ethically to keep in strict confidence all the information they learn by reading patient records. Actual patient names and other identifiers should not be used in written or oral student reports.
  - Students should never use their cellphone in the clinical setting.
  - Students should never use any computer in the clinical setting for personal communication.
  - Students should never take photos of any patient or clinical setting.
  - Students should never use any patient information on any social media platform.

The military clock uses one 24-hour time cycle instead of two 12-hour cycles (e.g., 9:00 AM is 0900 and 9:00 PM is 2100).

Table 20-1 Tips for Preventing Breaches in Patient Confidentiality

TYPE OF BREACH	HOW TO PREVENT IT

Computers	
Displaying information on a screen (especially handheld computers) that is viewed by unauthorized users	Make sure display screens do not face public areas. For portable devices, install encryption software that makes information unreadable or inaccessible.
Sending confidential e-mail messages via public networks such as the Internet, where they can be read by unauthorized users	Use encryption software when sending e-mail over public networks.
Sharing printers among units with differing functions and information (unauthorized users can read printouts)	Request that your unit have a separate printer not shared with another unit.
Copiers	
Discarded copies of patient health information in trash cans adjacent to copiers	Use secure disposal containers (similar to mailboxes) adjacent to copiers.
Cordless and Cellular Phones	
Holding conversations vulnerable to eavesdropping outsiders with scanning equipment	Use phones with built-in encryption technology.
Fax Machines	
Faxing confidential information to unauthorized persons	Before transmission, verify the fax number and that the recipient is authorized to receive confidential information.
Voice Pagers	
Sending confidential messages that can be overheard on the pager	Restrict use of voice pagers to nonconfidential messages.

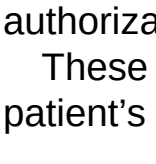
Health Information Privacy

The U.S. Office for Civil Rights enforces the Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule, which protects the privacy of individually identifiable health information; the HIPAA Security Rule, which sets national standards for the security of electronic protected health information; the HIPAA Breach Notification Rule, which requires covered entities and business associates to provide notification following a breach of unsecured protected health information; and the confidentiality provisions of the Patient Safety Rule, which protect identifiable information being used to analyze patient safety events and improve patient safety (https://www.hhs.gov/hipaa/for-professionals/index.html). Congress passed HIPAA in 1996. The HIPAA has been updated to include regulations about electronic patient information with the addition of the 2003 Security Rule and 2013 Omnibus rule.

Most facilities now require workers to undergo HIPAA training and to review and sign a confidentiality agreement, both when hired and at each performance review. As a student in a health care setting, you should discuss privacy guidelines with your instructor and nurse mentors.

According to HIPAA, patients have a right to:



- see and copy their health record.
- update their health record.
- get a list of the disclosures that a health care institution has made independent of disclosures made for the purposes of treatment, payment, and health care operations.
- request a restriction on certain uses or disclosures.
- choose how to receive health information.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Consider **Jason Chandler**, the adolescent brought to the ED by the police. The nurse needs to be knowledgeable about HIPAA regulations to ensure that Jason's confidentiality is maintained. In addition, the nurse should keep in mind that Jason is a minor, and any authorizations would probably require a parent's consent.

If a health institution wants to release patient health information (PHI) for purposes other than treatment, payment, or routine health care operations, the patient must be asked to sign an authorization. Box 20-2 provides a list of permitted disclosures of PHI and incidental disclosures.

Legal Alert

Take note! HIPAA legislation includes punishments for anyone caught violating patient privacy. Those who do so can be fined, face imprisonment, and/or revoked licensure. Even accidentally breaking the rules can result in penalties—and embarrassment—for you and your organization.

Facility Policies

Most facilities have specific policies regarding patient records. Everyone with access to the record (i.e., direct caregivers) is expected to maintain its confidentiality (see the earlier discussion about privacy). Most facilities grant student nurses access to patient records for educational purposes. In this instance, *the student assumes responsibility to hold patient information in confidence*. Never use a patient's name when preparing written or oral reports for school.

Box 20-2 **The Health Insurance Portability and Accountability Act of 1996 Authorization Rule**

If a health institution wants to release a patient's health information (PHI) for purposes other than treatment, payment, and routine health care operations, the patient must be asked to sign an authorization.

Permitted Disclosure of PHI

While the authorization rule covers most situations in which patient information is released for purposes other than treatment, payment, and routine health care operations, there are some exceptions to the authorization rule for the good of the general population.

These three exceptions show situations in which authorization is not required prior to releasing the patient's information:

Public Health Activities

- Tracking and notification of disease outbreaks
- Infection control
- Statistics related to dangerous problems with drugs or medical equipment

Law Enforcement and Judicial Proceedings

- Medical records crucial to the investigation and prosecution of a crime
- Medical records to identify victims of crime or disasters
- Medical personnel reporting incidents of child abuse, neglect, or domestic violence
- Medical records released according to a valid subpoena

Deceased People

- PHI needed by coroners, medical examiners, and funeral directors
- PHI needed to facilitate organ donations
- PHI provided to law enforcement in the case of a death from a potential crime

Incidental Disclosure of PHI

Incidental disclosure of PHI is defined as a secondary disclosure that cannot reasonably be prevented, is limited in nature, and occurs as a by-product of an otherwise permitted use or disclosure of PHI.

Examples of Permitted Incidental Disclosures

Use of sign-in sheets: Provided that the sign-in sheet does not contain information on the reason for the patient's visit

The possibility of a confidential conversation being overheard: Provided that the surroundings are appropriate for a confidential conversation and voices are kept down

Placing patient charts outside exam rooms: Provided that unauthorized public traffic is not permitted in

the area of the exam rooms and face sheets are turned toward the wall

Use of white boards: Provided that only the minimum information needed for the purpose of the white board is used

X-ray light boards that can be seen by passers-by: Provided that patient x-rays are not left unattended on the light board

Calling out names in the waiting room: Provided that the reason for the patient's visit is not mentioned

Leaving appointment reminder voicemail messages: Provided that the minimum amount of information is disclosed

Facility policies also indicate which personnel are responsible for recording on each form in the record; such policies may also describe the order in which the forms are to appear in the record. Additional policies may concern the frequency with which entries are to be made, whether routine care is recorded, how health personnel identify themselves after making an entry, which abbreviations are acceptable, and how recording errors are handled. Box 20-3 (on page 524) provides a list of commonly used abbreviations. Table 20-2 (on pages 525–527) identifies the Institute for Safe Medication Practices (ISMP) list of error-prone abbreviations, symbols, and dose designations. One of the strategies the Joint Commission is using to achieve National Patient Safety Goals is a list of "Do Not Use" abbreviations, acronyms, and symbols (Table 20-3 on page 528). Be sure to know the latest Joint Commission and facility policies regarding the use of abbreviations, acronyms, and symbols in your practice setting. It is now recommended that students minimize the use of abbreviations, and instead write or type out the full terms and other words to create a clear record for the caregivers who follow. Develop the habit of practicing whatever type of documentation you will be using in your clinical rotations.

Unfolding Patient Stories: Rashid Ahmed • Part 2

Recall from Chapter 9, **Rashid Ahmed**, a 50-year-old male admitted to the medical unit with a diagnosis of dehydration from severe nausea, vomiting, and diarrhea. What factors should the nurse consider when planning patient education for Rashid? How can the nurse create an environment conducive to learning? What teaching methods can be used to enhance the clarity and retention of information? Why is it important for the nurse to evaluate learning after education is provided, and what evaluation methods can be used?

Care for Rashid and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

The storage of patient records after treatment is a function of the health facility's record department. Many patient records are microfilmed for compact storage or are entered into a computer to expedite accessibility of information.

Box 20-3 **Abbreviations and Symbols Commonly Used by Health Practitioners[a]**

Activities

AMB	ambulatory
BRP	bathroom privileges
CBR	complete bed rest
OOB	out of bed
up ad lib	up as desired

Assessment Data

abd	abdomen
BP	blood pressure

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

bx	biopsy
C	Celsius (centigrade)
c/o	complains of
CTA	clear to auscultation
dx	diagnosis
F	Fahrenheit
FUO	fever of unknown origin
GI	gastrointestinal
GU	genitourinary
H/A	headache
h/o	history of
HPI	history of present illness
Imp	impressions
lt or l	left
MAE	moves all extremities
NAD	no apparent distress
NKA	no known allergies
N/V	nausea and vomiting
neg	negative
P	pulse
PE	physical examination
PMH	past medical history
R	respirations
R/O	rule out
ROS	review of systems
rt or ®	right
SOB	short of breath
Sx	symptoms
T	Temperature
Tx	Treatment
⊕	positive
Θ	negative

Diseases

ASCVD	arteriosclerotic cardiovascular disease
ASHD	arteriosclerotic heart disease
BPH	benign prostatic hypertrophy
CA	cancer
CAD	coronary artery disease
CHF	congestive heart failure
COPD	chronic obstructive pulmonary disease
CVA	cerebrovascular accident
DM	diabetes mellitus

HTN (↑ BP)	hypertension
MI	myocardial infarction
PE	pulmonary emboli
PVD	peripheral vascular disease
STD	sexually transmitted disease
STI	sexually transmitted infection
URI	upper respiratory infection
UTI	urinary tract infection

Diagnostic Studies

ABG	arterial blood gases
BE	barium enema
CBC	complete blood count
CO2	carbon dioxide
C&S	culture and sensitivity
CXR	chest x-ray
ECG (EKG)	cardiogram
lytes	electrolytes
RBC	red blood cells
UA	urinalysis
UGI	upper GI
WBC	white blood cells

Symbols

↑	increase
↗	increasing
↓	decrease
↙	decreasing
2°	secondary to
=	equal to
≠	unequal
♀	female
♂	male
°	degree
▲	change
X̄	except

Miscellaneous

ā	before
ad lib	as desired
AMA	against medical advice
ASAP	as soon as possible
BM	bowel movement

BSD	bedside drainage
c̄ (C)	with
CABG	coronary artery bypass graft
CPR	cardiopulmonary resuscitation
DNR (no code)	do not resuscitate
Dsg	dressing
dx	diagnosis
FOB	foot of bed
Fx	fracture
GHWT	good handwashing technique
HOB	head of bed
Hx	history
I&O	intake and output
IM	intramuscular
IV	intravenous
KVO	keep vein open
NG	nasogastric
noc	night
NPO (npo)	nothing by mouth
NS (NIS) (N/S)	normal saline
O_2	oxygen
OT	occupational therapy
p̄	after
postop	postoperative
preop	preoperative
prep	preparation
PRN (p.r.n.)	as needed
PT	physical therapy
pt	patient
ROM	range of motion
RX	treatment
s̄(S)	without
SOB	side of bed
S/P	status post
STAT	immediately
SubQ or SQ	subcutaneous
TF	tube feeding
TPR	temperature, pulse, respirations
TX	treatment
VS	vital signs
WA	while awake

×	times

[a]Use only those abbreviations and symbols accepted by your institution.

Table 20-2 ISMP Error-Prone Abbreviations

The abbreviations, symbols, and dose designations found in this table have been reported to ISMP through the ISMP National Medication Errors Reporting Program (ISMP MERP) as being frequently misinterpreted and involved in harmful medication errors. They should NEVER be used when communicating medical information. This includes internal communications, telephone/verbal prescriptions, computer generated labels, labels for drug storage bins, medication administration records, as well as pharmacy and prescriber computer order entry screens.

ABBREVIATIONS	INTENDED MEANING	MISINTERPRETATION	CORRECTION
µg	Microgram	Mistaken as “mg”	Use “mcg”
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use “right ear,” “left ear,” or “each ear”
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use “right eye,” “left eye,” or “each eye”
BT	Bedtime	Mistaken as “BID” (twice daily)	Use “bedtime”
cc	Cubic centimeters	Mistaken as “u” (units)	Use “mL”
D/C	Discharge or discontinue	Premature discontinuation of medications if D/C (intended to mean “discharge”) has been misinterpreted as “discontinued” when followed by a list of discharge medications	Use “discharge” and “discontinue”
IJ	Injection	Mistaken as “IV” or “intrajugular”	Use “injection”
IN	Intranasal	Mistaken as “IM” or “IV”	Use “intranasal” or “NAS”
HS hs	Half-strength At bedtime, hours of sleep	Mistaken as bedtime Mistaken as half-strength	Use “half-strength” or “bedtime”
IU[a]	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use “units”
o.d. or OD	Once daily	Mistaken as “right eye” (OD-oculus dexter), leading to oral liquid medications administered in the eye	Use “daily”
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use “orange juice”
Per os	By mouth, orally	The “os” can be mistaken as “left eye” (OS—oculus sinister)	Use “PO,” “by mouth,” or “orally”
q.d. or QD[a]	Every day	Mistaken as q.i.d., especially if the period after the “q” or the tail of the “q” is misunderstood	Use “daily”

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		as an “i”	
qhs	Nightly at bedtime	Mistaken as “qhr” or every hour	Use “nightly”
qn	Nightly or at bedtime	Mistaken as “qh” (every hour)	Use “nightly” or “at bedtime”
q.o.d. or QOD[a]	Every other day	Mistaken as “q.d.” (daily) or “q.i.d. (four times daily) if the “o” is poorly written	Use “every other day”
q1d	Daily	Mistaken as q.i.d. (four times daily)	Use “daily”
q6pm, etc.	Every evening at 6 pm	Mistaken as every 6 hours	Use “daily at 6 PM” or “6 PM“ o daily”
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as “5 every;” the “q” in “sub q” has been mistaken as “every” (e.g., a heparin dose ordered “sub q 2 hours before surgery” misunderstood as every 2 hours before surgery)	Use “subcut” or “subcutaneously”
ss	Sliding scale (insulin) or ½ (apothecary)	Mistaken as “55”	Spell out “sliding scale;” use “one half” or “½”
SSRI	Sliding scale regular insulin	Mistaken as selective serotonin reuptake inhibitor	Spell out “sliding scale (insulin)”
SSI	Sliding scale insulin	Mistaken as Strong Solution of Iodine (Lugol’s)	
i/d	One daily	Mistaken as “tid”	Use “1 daily”
TIW or tiw	3 times a week	Mistaken as “3 times a day” or “twice in a week”	Use “3 times weekly”
U or u[a]	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4U seen as “40” or 4u seen as “44”); mistaken as “cc” so dose given in volume instead of units (e.g., 4u seen as 4cc)	Use “unit”
UD	As directed (“ut dictum“)	Mistaken as unit dose (e.g., diltiazem 125 mg IV infusion “UD” misinterpreted as meaning to give the entire infusion as a unit [bolus] dose)	Use “as directed”
DOSE DESIGNATIONS AND OTHER INFORMATION	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
Trailing zero after decimal point	1 mg	Mistaken as 10 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in

(e.g., 1.0 mg)[a]			whole numbers
“Naked” decimal point (e.g., .5 mg)[a]	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Abbreviations such as mg. or mL. with a period following the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period
Drug name and dose run together (especially problematic for drug names that end in “l” such as Inderal 40 mg; Tegretol 300 mg)	Inderal 40 mg Tegretol 300 mg	Mistaken as Inderal 140 mg Mistaken as Tegretol 1,300 mg	Place adequate space between the drug name, dose, and unit of measure
Numerical dose and unit of measure run together (e.g., 10 mg, 100 mL)	10 mg 100 mL	The “m” is sometimes mistaken as a zero or two zeros, risking a 10- to 100-fold overdose	Place adequate space between the dose and unit of measure
Large doses without properly placed commas (e.g., 100000 units; 1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as 10,000 or 1,000,000; 1000000 has been mistaken as 100,000	Use commas for dosing units at or above 1,000, or use words such as 100 “thousand” or 1 “million” to improve readability
DRUG NAME ABBREVIATIONS	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
To avoid confusion, do not abbreviate drug names when communicating medical information. Examples of drug name abbreviations involved in medication errors include:			
APAP	acetaminophen	Not recognized as acetaminophen	Use complete drug name
ARA A	vidarabine	Mistaken as cytarabine (ARA C)	Use complete drug name
AZT	zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
CPZ	Compazine (prochlorperazine)	Mistaken as chlorpromazine	Use complete drug name
DPT	Demerol-Phenergan-Thorazine	Mistaken as diphtheria-pertussis-tetanus (vaccine)	Use complete drug name
DTO	diluted tincture of opium, or deodorized tincture of opium (Paregoric)	Mistaken as tincture of opium	Use complete drug name
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The “H” is misinterpreted as “K”)	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone	Use complete drug name

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		(seen as HCT250 mg)	
$MgSO_4$[a]	magnesium sulfate	Mistaken as morphine sulfate	Use complete drug name
MS, MSO_4[a]	morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
MTX	Methotrexate	Mistaken as mitoxantrone	Use complete drug name
NoAC	Novel/new anticoagulant	Mistaken as “no anticoagulant”	Use complete drug name
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
PTU	propylthiouracil	Mistaken as mercaptopurine	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
TAC	triamcinolone	Mistaken as tetracaine, Adrenalin, cocaine	Use complete drug name
TNK	TNKase	Mistaken as “TPA”	Use complete drug name
TPA or tPA	tissue plasminogen activator, Activase, (alteplase)	mistaken as TNKase (tenectaplase) or as another tissue plasminogen activator, Retavase (retaplase)	Use complete drug name
$ZnSO_4$	zinc sulfate	Mistaken as morphine sulfate	Use complete drug name
STEMMED DRUG NAMES	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
“Nitro” drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
“Norflox”	norfloxacin	Mistaken as Norflex	Use complete drug name
“IV Vanc”	intravenous vancomycin	Mistaken as Invanz	Use complete drug name
SYMBOLS	**INTENDED MEANING**	**MISINTERPRETATION**	**CORRECTION**
ʒ	Dram	Symbol for dram mistaken as “3”	Use the metric system
♏	Minim	Symbol for minim mistaken as “mL”	
x3d	For three days	Mistaken as “3 doses”	Use “for three days”
> and <	Greater than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; “<10” mistaken as “40”	Use “greater than” or “less than”
/(slash mark)	Separates two doses or indicates “per”	Mistaken as the number 1 (e.g., “25 units/10 units” misread as “25 units and 110” units)	Use “per” rather than a slash mark to separate doses
@	At	Mistaken as “2”	Use “at”
&	And	Mistaken as “2”	Use “and”
+	Plus or and	Mistaken as “4”	Use “and”
°	Hour	Mistaken as a zero (e.g., q2° seen as q20)	Use “hr,” “h,” or “hour”
Φ or	Zero, null sign	Mistaken as numerals 4, 6, 8, and 9	Use 0 or zero, or describe intent using whole words

[a]These abbreviations are included on The Joint Commission's "minimum list" of dangerous abbreviations, acronyms, and symbols that must be included on an organization's "Do Not Use" list, effective January 1, 2004. Visit www.jointcommission.org for more information about this Joint Commission requirement.

Source: © Institute for Safe Medication Practices. (2021). List of Error Prone Abbreviations. https://www.ismp.org/recommendations/error-prone-abbreviations-list

Table 20-3 The Joint Commission Official "Do Not Use" List[a]

DO NOT USE	POTENTIAL PROBLEM	USE INSTEAD
U, u (for unit)	Mistaken for "0" (zero), the number "4" (four), or "cc"	Write "unit"
IU (International Unit)	Mistaken for IV (intravenous) or the number 10 (ten)	Write "International Unit"
Q.D., QD, q.d., qd (daily)	Mistaken for each other	Write "daily"
Q.O.D., QOD, q.o.d, qod (every other day)	Period after the Q mistaken for "I" and the "O" mistaken for "I"	Write "every other day"
Trailing zero (X.0 mg)[b]	Decimal point is missed	Write X mg
Lack of leading zero (.X mg)		Write 0.X mg
MS	Can mean morphine sulfate or magnesium sulfate	Write "morphine sulfate"
MSO_4 and $MgSO_4$	Confused for one another	Write "magnesium sulfate"

[a]Applies to all orders and all medication-related documentation that are handwritten (including free-text computer entry) or on preprinted forms.

[b]Exception: A "trailing zero" may be used only when required to demonstrate the level of precision of the value being reported, such as for laboratory results, imaging studies that report the size of lesions, or catheter/tube sizes. It may not be used in medication orders or other medication-related documentation.

Source: © The Joint Commission. (2018). Official "Do Not Use" List. FACT SHEET. https://www.jointcommission.org/-/media/tjc/documents/resources/patient-safety-topics/patient-safety/do_not_use_list_9_14_18.pdf.

You should also know your facility's policies regarding the patient's right to access records. Be sure to check the policy where you work to find out answers to the following common questions from patients:

- Can I take my patient record home?
- Can I access my patient record electronically?
- How long do you retain records?
- How long will it take to get a copy of my record?
- How much does it cost?
- I do not want some parts of my record (e.g., psychiatric information) released to anyone. What do I do?
- What can I do to get errors in my record corrected?
- May I look at my family's medical record?
- Who can look at my record?
- Who do I tell if my name has changed?

Your facility should have an information officer or clinical informaticist who can help you answer these questions.

Delegating Documentation

An issue of growing importance concerns documentation made by assistive personnel. Because professional nurses frequently supervise the care that assistive personnel give, it must be clear which assessments and interventions may be charted by assistive personnel and which require documentation by a professional nurse. Make sure you know and follow your facility's protocols. As a general rule, you should only document the assessments and interventions you perform.

Purposes of Patient Records

Patient records serve many purposes. The ANA states that the most important of these is "communicating within the health care team and providing information for other professionals, primarily for individuals and groups involved with accreditation, credentialing, legal, regulatory and legislative, reimbursement, research, and quality activities" (ANA, 2010, p. 5).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Communication

The primary purpose of the patient record is to help health care professionals from different disciplines (who interact with the patient at different times) communicate with one another. Communication fosters continuity of care. For example, a critically ill patient in an academic health center may be seen by an attending health care provider, several consulting physicians, different teams of medical residents, an assigned social worker or case manager, assorted therapists, a hospital chaplain, and many nurses. Because these people are never all in the same room at the same time, the patient record is the primary means of communication. A nurse may check the patient record to see if the health care provider has spoken with the patient or the patient's surrogate about a do-not-resuscitate order (DNR) or an allow natural death order (AND). The health care provider may read the nurse's note to see how the family is responding to the recommendation to withhold or withdraw life-sustaining treatment.

Note also that other health care professionals make judgments about nurses and nursing's contributions to the health care team partially on the basis of what is documented in the patient record.

Diagnostic and Therapeutic Orders

Patient records include diagnostic and therapeutic orders. Anyone reviewing the chart can find all the diagnostic studies ordered for the patient since admission, the results of these studies, and related orders for care. Illegible handwritten notes have been the source of many inaccuracies in patient health records. Whenever you are unsure of what has been written or entered in an electronic record, check the original order. Never guess about what is written. A patient's life and your license are literally at risk if you incorrectly transcribe or execute an order.

VERBAL ORDERS

Verbal orders (VOs) must be given directly by the physician or nurse practitioner to a registered professional nurse or registered professional pharmacist, who receives, reads back, documents and executes the order. In "**read-back**," the recipient reads back the message as they heard and interpreted it. The person giving the order then confirms that such recording and interpretation of the order is correct.

Health care institutions limit use of verbal orders and have individual facility policies for their use. Here is a sample institutional policy for VOs:

A. The registered professional nurse or registered professional pharmacist who receives the VO will:
   a. record the orders in the patient's medical record with the letters VO (verbal order).
   b. read back the order to verify accuracy of the order.
   c. date and note the time the orders were issued
   d. record VOs, the name of the physician or nurse practitioner who issued the orders, followed by the nurse's own name and title.

B. At the soonest possible time, the physician or nurse practitioner who issued the VOs must:
   a. review the orders to ascertain whether they are correct.
   b. sign the orders with name, title, and pager number.
   c. date and note the time they sign the orders.

C. The registered professional nurse must see that the orders are transcribed according to the facility's procedure.

D. Verbal orders should be limited to urgent situations where immediate written or electronic communication is not feasible (National Coordinating Council for Medication Error Reporting and Prevention, 2020).

E. According to the Institute for Safe Medication Practices, 2017, the potential for verbal orders to be misunderstood, misheard, or transcribed incorrectly make them error prone. Health care facilities should have policies and procedures specifying when verbal orders are acceptable, defining the prohibitions and limitations on verbal orders, and establishing requirements for clear communication of verbal orders, including a read-back process (Cohen, 2017).

F. According to Wakefield et al. (2012, p. 11), "recommendations to ameliorate potential dangers associated with verbally communicated orders include 'read-backs' and other strategies to improve the safety of VOs and/or limit their use, and to ensure that the verbal communication was understood and accurately transcribed into the hospitals' ordering systems."

Care Planning

Each health care professional working with the patient has access to the patient's baseline and ongoing data and can see how the patient is responding to the treatment plan from day to day. For example, if recorded data indicate that a patient is gradually becoming weaker and cannot now tolerate ambulation, orders for physical therapy and other nurse-initiated ambulation need to be modified. Modifications of the care plan are based on these data.

Think back to **Phillippe Baron**, the patient who had undergone a colonoscopy. The nurse uses the patient's chart to obtain information about the patient, including events of the colonoscopy and how the patient responded, to develop an individualized discharge teaching plan.

Quality Process and Performance Improvement

"Documentation is the primary source of evidence used to continuously measure performance outcomes against predetermined standards" (ANA, 2010, p. 7). Records may be reviewed to evaluate the quality of care patients have received and the competence of the nurses providing that care. For example, in a nursing audit, a committee decides in advance the standards of care it wants to evaluate (e.g., pertaining to nursing assessment, nursing documentation, or safety measures). A number of records are then randomly selected and reviewed for evidence that the nurses met the selected standards of care. If deficiencies are found, in-service training may be used to remedy the problem and improve the quality of care. Accrediting facilities, such as the Joint Commission on Accreditation of Healthcare Organizations (JCAHO), may also use record review to determine whether a particular facility or health care institution is meeting its standards.

Research

Researchers may study patient records, hoping to learn how best to recognize or treat identified health problems from the study of similar cases. The aim is to promote evidence-based practice in nursing and quality health care.

Decision Analysis

Information from record review often provides the data needed by administrative strategic planners to identify needs as well as the means and strategies most likely to address these needs. Record review may reveal both underused and overused services, patients with prolonged stays who require special assistance, and financial information about which services generate revenue compared with those that cost the institution or facility money.

Education

Health care professionals and students reading a patient's record can learn a great deal about the clinical manifestations of particular health problems, effective treatment modalities, and factors that affect patient goal achievement.

Credentialing, Regulation, and Legislation

Documentation allows reviewers to monitor health care practitioners' and the health care facility's compliance with standards governing the profession and provision of care.

Legal Documentation

Patient records are legal documents that might be used as evidence in court proceedings. One in four malpractice suits are decided on the basis of the patient's record. Documentation plays an important role in implicating or absolving health care practitioners charged with improper care. The record can also be used in accident or injury claims made by the patient. All nurses need to be well informed about facility policies and professional standards for documentation.

Reimbursement

Patient records are used to demonstrate to payers (e.g., insurance companies) that patients received the intensity and quality of care for which reimbursement is being sought.

Historical Documentation

Because all entries on records are dated, the record has value as a historical document. Years later, information concerning a patient's past health care may be pertinent.

Methods of Documentation

Different methods of documentation are used by different health care facilities to achieve certain aims. Understanding a variety of systems helps nurses adapt quickly in new practice settings.

Computerized Documentation and Electronic Health Records

Increasingly, computer systems are used for nursing documentation in the patient record. In such systems the nurse may:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

. call up the admission assessment tool on the computer screen and key in patient data (see Chapter 15 for illustrations).
. develop the care plan using computerized care plans available for each diagnosis or problem.
. add to the patient database as new data are identified and modify the care plan accordingly.
. receive a work list showing the treatments, procedures, and medications necessary for each patient throughout the care of the patient.
. document care immediately, using the computer terminal at the patient's bedside.

According to HealthIT.gov (n.d.), "Electronic health records (EHRs) and the ability to exchange health information electronically can help you provide higher quality and safer care for patients while creating tangible enhancements for your organization." EHRs help providers better manage care for patients and provide better health care by:

- Providing accurate, up-to-date, and complete information about patients at the point of care
- Enabling quick access to patient records for more coordinated, efficient care
- Securely sharing electronic information with patients and other clinicians
- Helping providers more effectively diagnose patients, reduce medical errors, and provide safer care
- Improving patient and provider interaction and communication, as well as health care convenience (Fig. 20-1)
- Enabling safer, more reliable prescribing
- Helping promote legible, complete documentation and accurate, streamlined coding and billing
- Enhancing privacy and security of patient data
- Helping providers improve productivity and work–life balance
- Enabling providers to improve efficiency and meet their business goals
- Reducing costs through decreased paperwork, improved safety, reduced duplication of testing, and improved health (https://www.healthit.gov/faq/what-are-advantages-electronic-health-records)

FIGURE 20-1. Computerized bedside charting allows the nurse to remain in contact with the patient while electronically documenting patient information. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

With computer-based records, or **electronic health records (EHRs)**, data can be distributed among many caregivers in a standardized format, allowing them to compare and uniformly evaluate patient progress easily. Besides tracking the progress of individual patients, computerized outcome information can aid in comparing the progress of groups of patients with similar diagnoses. These results will contribute to research; education; and, ultimately, better and more efficient nursing practice. Box 20-4 defines terms used to discuss electronic records in health care.

The Agency for Healthcare Research and Quality (AHRQ, 2018) reports EHRs can improve the quality and safety of health care in the following ways:

- Help reduce medical errors and adverse events
- Enable better documentation and file organization
- Provide patients with information that assists their adherence to medication regimens and scheduled appointments
- Assist health care providers track their treatment protocols
- Allow patient information to flow between and within health care facilities and practices can enhance primary care provider decision making and improve care coordination (Cross et al., 2015)
- Allow faster and more complete access to the patient record and may improve communication among members of the health care team (some evidence exists that electronic documentation may be associated with improved patient outcomes and decreased costs [Hripcsak & Albers, 2013])
- Improve the communication and management of laboratory information in patient care, particularly results reporting and test order management (Henricks, 2011)
- EHR clinical decision support (CDS) systems, provide appropriate, timely, patient-specific reminders and information and are essential to cope with the growth in medical knowledge; when implemented effectively, CDS has been shown to improve quality and can be particularly effective for increasing appropriate use of evidence-based preventive services (Wright et al., 2015)

- EHR computer provider order entry (CPOE) is associated with a 13% to 99% reduction in medication errors and a 30% to 84% reduction in adverse drug events (ADEs) (Ammenwerth et al., 2008)

Box 20-4 Terms Used to Discuss Electronic Records in Health Care

Computerized Provider Order Entry (CPOE): This section of the EHR is for the orders written by the health care provider that are deemed necessary for the patient such as required lab tests, procedures, medications, and treatments. This section was formerly known as the section of the paper medical record known as "physician orders."

Clinical Decision Support (CDS): CDS includes academic information, medical logic, and analytic programs built into the EHR that can assist the health care provider make diagnoses and clinical decisions about patient care. Examples of CDS data include patient genetic information, past patient health history data that influences current health problem, potential drug–drug interactions, pharmacogenomic information applicable to the patient, interpretation of abnormal lab test results, data received from the medical devices used in patient care such as infusion pumps, ventilators, and bedside monitors. CDS applications continue to be promoted as one of the key features of EHRs. CDS applications are constantly being upgraded within EHRs. CDS systems give the health care provider ability to synthesize fragments of evidence documented in the entire record to understand the etiology of a disease and its clinical manifestation in individual patients. A comprehensive discussion of current CDS capabilities can be found in Greenes' "Clinical Decision Support" (Greenes, 2014).

Electronic health record (EHR): The EHR is the patient care record created when facilities under different ownership share their data. The goal is for this sharing to be nationwide, creating a situation in which a person's health care record is accessible by designated health care providers anywhere in the nation. The patient will decide which portions of a record will be available to whom.

Electronic medical record (EMR): An EMR is an electronic patient care record created by a facility or facilities having common ownership. Although these EMRs today are often called EHRs, they are not true EHRs because the data are not shared between providers in facilities under different ownership.

Health information exchange (HIE): An HIE is an organization that provides services to enable the electronic sharing of health-related information.

Electronic database: An electronic database is a collection of data that allows easy searching and easy retrieval of similar pieces of data from many records.

Medication Administration Record (MAR): The electronic Medication Administration Record (MAR or eMAR) is used to electronically track and record administration of patient medications. At a minimum the MAR includes the patient's name, and each medication's name, dose, frequency, and route. The MAR is commonly linked to bar code medication administration systems. For example, when a nurse scans a bar code on their identification badge, on the patient's wristband, and on the medication to be administered, the data are delivered to a computer software system where algorithms check various databases and generate real-time warnings or approvals. Most systems then automatically document, in real time, the administration of the medication in an eMAR (Shah et al., 2016).

Personal Health Records (PHRs): These are patient records of their own medical data and health history. PHRs can be interfaced with applications within EHRs and are used by most large facilities. PHRs are allowing patients to take a more active role in managing their health care by documenting their past health history and current health care goals. This communication feature has enhanced patient-centered care provided by health care providers.

Source: Evans, R. S. (2016). Electronic health records: Then, now, and in the future. *Yearbook of Medical Informatics*, *25*(Suppl 1), S48–S61. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5171496/pdf/ymi-11-0s48.pdf

In spite of the touted benefits of EHRs, many providers, including nurses, report high dissatisfaction. According to Balestra (2017), "Although these systems promised to improve the quality of patient care, increase efficiency, and reduce costs, health care providers are finding that current EHRs instead require time-consuming data entry, can interfere with patient interactions, and cause medical errors." Nurse Stephanie Drobny shared her dismay when a patient grumbled about nurses always talking behind his back—and she realized it happened when they were charting in his room. "The idea that charting about a patient in his presence would be perceived as secretive had never occurred to me" (Balestra, 2017, p. 11). Drobny responded by flipping her position so that she now sits side by side with the patient, and they both focus on the computer and enter the responses together. While the initial assessment now takes 20 to 30 minutes, she discovered that patients have become partners, their health literacy is improved, and she more rapidly gains their trust: a big payoff for a simple change.

Pfeifer (2020), reporting on a Kaiser Health News and Fortune Magazine study on EHRs (Schulte & Fry, 2019), describes serious consequences that can befall patients with the use of EHRs. Rather than the promised higher quality care, lower costs, and an overall healthier population, the authors describe "systemic failures in transmission of

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

physician orders, mix-ups in patient profiles that could lead to catastrophic medication errors, and issues with 'interface,' where online systems used by pharmacies and laboratories might fail to communicate with each other." See the Office of the National Coordinator for Health Information Technology nine SAFER Guides (https://www.healthit.gov/topic/safety/safer-guides).

With the increasing use of computerized patient information systems to store and analyze patient data have come policies and procedures to ensure the privacy and confidentiality of patient information. Policies should specify what types of patient information can be retrieved, by whom, and for what purpose. Patient consent is necessary for the use and release of any stored information that can be linked to the patient.

The ANA, the American Medical Record Association, and the Canadian Nurses Association offer the following guidelines and strategies for safe computer charting:

- Never give your personal password or username to anyone, including any other health care provider.
- Don't leave a computer terminal unattended after you have logged on.
- Know and follow the recommended protocol for correcting errors. To correct an error after it has been entered, mark the entry "mistaken entry," add the correct information, and date and initial the entry. If you record information in the wrong chart, write "mistaken entry—wrong chart" and sign off. Follow similar guidelines in electronic records.
- Never create, change, or delete records unless you have specific authority to do so.
- If you inadvertently delete part of the permanent record, type an explanation into the computer file with the date, time, and your initials, and submit an explanation in writing to your manager.
- Do not leave information about a patient displayed on a monitor where others may see it. Keep a log that accounts for every printout of a computerized file that you've generated from the system.
- Never use email to send protected health information unless it has been encrypted to protect it from unauthorized access.
- Follow the facility's confidentiality procedures for documenting sensitive material, such as a diagnosis of acquired immunodeficiency syndrome (AIDS) or human immunodeficiency virus (HIV) infection.

Legal Alert

Remember, each time you log in to an electronic health record (EHR) with your password, you create a trail that can be traced, and you are liable for everything you document—or fail to document.

PERSONAL HEALTH RECORDS

Many people today are preparing online personal health records (PHRs) to manage their health care via computer. These records contain the person's medical history, including diagnoses, symptoms, and medications. Some patients scan in doctors' notes, test results, CT images, and insurance information. They may give health care professionals their password so that they can log on and may give permission to share the record with other family members. The chief reason for a PHR is to provide easy access to up-to-date, complete health information to assist in self-care and communication with providers.

Tethered/connected PHRs are the most common kind of personal health record. A tethered, or connected, PHR is linked to a specific health care organization's EHR system or to a health plan's information system. With a tethered PHR, patients can access their own records through a secure portal and see, for example, the trend of their lab results over the last year, their immunization history, or due dates for screenings.

When talking with patients who are considering using a PHR, advise them to check the service's privacy policy carefully to see how much control they will have over their information and whether the service can share or exchange their data, and ask their health care providers if they are willing to read their PHR. Helpful information may be found at https://www.healthit.gov/faq/what-are-benefits-personal-health-records and https://www.healthit.gov/sites/default/files/about-phrs-for-providers-011311.pdf.

HEALTH INFORMATION EXCHANGE

An electronic **health information exchange (HIE)** allows physicians, nurse practitioners, physician assistants, nurses, pharmacists, other health care providers, and patients to appropriately access and securely share a patient's vital medical information electronically, improving the speed, quality, safety, and cost of patient care. Appropriate, timely sharing of vital patient information can better inform decision making at the point of care and allow providers to avoid readmission and medication errors, improve diagnoses, and decrease duplicate testing (Health Information Exchange, n.d.). Benefits of an HIE include the following:

- Provides a vehicle for improving quality and safety of patient care.
- Provides a basic level of interoperability among EHRs maintained by individual health care providers and organizations.
- Stimulates consumer education and patients' involvement in their own health care.
- Helps public health officials meet their commitment to the community.
- Creates a potential loop for feedback between health-related research and actual practice.

- Facilitates efficient deployment of emerging technology and health care services.
- Provides the backbone of technical infrastructure for leverage by national and state-level initiatives (Health Information Exchange, n.d.).

The following resources provide more information about electronic health and medical records and HIE:

- American Nursing Informatics Association: www.ania.org
- HealthIT.gov: www.healthit.gov
- Healthcare IT News: www.healthcareitnews.com
- Healthcare Information and Management Systems Society (HIMSS): www.himss.org
- American Health Information Management Association (AHIMA): https://www.ahima.org/

Source-Oriented Records

Many nurses, especially in rural and underserved areas, continue to practice in settings that do not use EHRs. Traditional paper records are still used in such settings, in a variety of formats. A **source-oriented record** is a paper format in which each health care group keeps data on its own separate form. Sections of the record are designated for nurses, health care providers, laboratory, x-ray personnel, and so on. Notations are entered chronologically, with the most recent entry being nearest the front of the record. An advantage of the source-oriented record is that each discipline can easily find and chart pertinent data. The main disadvantage is that data are fragmented, making it difficult to track problems chronologically with input from different groups of professionals.

Box 20-5 **Examples of Forms and Information in Source-Oriented Patient Records**

Admission Record

Legal name, identification number
Age, birth date, biologic sex/gender
Marital status
Occupation and employer
Religious preference
Next of kin and person to notify in case of emergency
Date, time, reason for admission
Name of the attending health care provider
Insurance information
Discharge data

Admission Nursing Assessment (see Chapter 15)

Results of nursing history and physical assessment

Graphic Record

Daily temperatures, pulse and respiratory rates, blood pressure (vital signs), pain level
Daily weight
Special measurements, such as the patient's fluid intake and output

Flow Sheet to Record Routine Care (see Fig. 20-5)

Respiratory	IV therapy	Sleep
Cardiac	Wound	Safety
Pain	Tubes	Equipment
Nutrition	Hygiene	Teaching
Elimination	Activity	Progress sheet

Narrative Nurse's Notes

Descriptions of pertinent observations of patient
Statements that specify the nursing care, including teaching, received by patient and patient's responses to nursing care
Statements that describe patient's condition and progress, or lack of progress, toward recovery and goal achievement
Descriptions of patient's complaints and how patient is coping or failing to cope with them, and nursing's response

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Medication Record (see Chapter 30)

Name of prescribed medications administered on a regular or PRN basis
Dosage of medication administered
Route by which medication was administered, unless given orally
Time medication was administered
Name or initials of person administering the medication

Medical History and Examination Record

Results of physical examination performed by health care provider
Current medical condition
Health history, including previous illnesses
Family medical history
Confirmed or tentative diagnosis
Plan of medical therapy

Health Care Provider's Order Record

Orders for medications
Orders for treatments
Other directives pertinent to a particular patient's care

Health Care Provider's Progress Notes

Interpretations of patient's pathology
Responses of patient to medical therapy

Miscellaneous Forms

Laboratory reports
X-ray film reports
Consultation reports
Dietary requirements
Results of social service consultations
Types and results of physical, respiratory, and x-ray therapy

Although the specifics vary among health facilities, the general characteristics of source-oriented records are essentially the same. Types of forms typically used in a source-oriented patient record are shown in Box 20-5. Notes written to inform caregivers of the progress a patient is making toward achieving expected outcomes are called **progress notes**. Progress notes written by nurses in a source-oriented record are **narrative notes** and address routine care, patient data, and patient problems identified in the care plan. They include a description of the status of the problem, related nursing interventions, patient responses to interventions, and needed revisions to the care plan.

Alfaro-LeFevre (2014, p. 183) identifies the following charting memory jogs when writing narrative notes:

- Assessment, Intervention, Response, Action (AIRA). Chart the assessment data you observed, the interventions you performed, the patient's response to interventions, and any actions you took based on the response.
- Date, Action, Response, Action (DARA). This has the same meaning as above.

Problem-Oriented Medical Records

Another type of paper record used in some health facilities is the **problem-oriented medical record (POMR)**, or problem-oriented record. The POMR is organized around a patient's problems rather than around sources of information. With POMRs, all health care professionals record information on the same forms. The advantages of this type of record are that the entire health care team works together in identifying a master list of patient problems and contributes collaboratively to the care plan. Progress notes clearly focus on patient problems. The POMR includes the defined database, problem list, care plans, and progress notes.

The **SOAP format** (Subjective data, Objective data, Assessment [the caregiver's judgment about the situation], Plan) is used to organize entries in the progress notes of the POMR. Variants of the SOAP format include SOAPE, SOAPIE, and SOAPIER (Intervention, Evaluation, and Response). Caregivers select numbered problems from the master list on the front of the patient record and then work up the problem or "SOAP it" on the progress sheet. Some nurses believe that the SOAP method of charting focuses too narrowly on problems and advocate instead a return to the traditional narrative format.

PIE Charting: Problem, Intervention, Evaluation

The **PIE charting** system is unique in that it does not develop a separate care plan. The care plan is incorporated into the progress notes, which identify problems by number (in the order they are identified). In this documentation system, a patient assessment is performed and documented at the beginning of each shift using preprinted fill-in-the-blank assessment forms (flow sheets). Patient problems identified in these assessments are numbered, documented in the progress notes, worked up using the Problem, Intervention, Evaluation (**PIE**) format—or Problem, Intervention, Evaluation, Revision (**PIER**), and evaluated each shift. Resolved problems are dropped from daily documentation following the nurse's review. Continuing problems are documented and numbered each day. One advantage of this system is that it promotes continuity of care. It also saves time because there is no separate care plan. The disadvantage of not having a formal care plan is that nurses need to read all the nursing notes to determine problems and planned interventions before initiating care. Unlike the SOAP method, which originated from the medical record, the PIE format has a nursing origin.

Focus Charting

The purpose of **focus charting** is to bring the focus of care back to the patient and the patient's concerns. Instead of a problem list or list of nursing or medical diagnoses, a focus column is used that incorporates many aspects of a patient and patient care. The focus may be a patient strength, problem, or need. Topics that may appear in the focus column include patient concerns and behaviors, therapies and responses, changes of condition, and significant events such as teaching, consultation, monitoring, management of activities of daily living, or assessment of functional health patterns. The narrative portion of focus charting uses the Data–Action–Response (DAR) format (Fig. 20-2). The principal advantage of focus charting is the holistic emphasis on the patient and the patient's priorities. Ease of charting is also cited as an advantage of focus charting because each note does not need to incorporate data, action, and response. Some nurses report, however, that the DAR categories are artificial and not helpful when documenting care.

Date/Time	Focus	Patient Care Notes
7/11/25 0915	High risk for trauma	**DATA:** Patient crying when I entered room; confided that she is afraid to go home because her injuries are the result of her husband's battery, which she had not previously wanted anyone to know. **ACTION:** Attending notified and discharge cancelled; Abuse network called with patient's permission and they are sending a counselor this afternoon to talk with her. C. Taylor, RN
1000	Pain	**DATA:** Patient complaining of pain in right rib area **ACTION:** Tylenol 3 administered as ordered. C. Taylor, RN
1030	Pain	**RESPONSE:** Patient reports relief from rib pain, still anxious about aftermath of discharge. C. Taylor, RN

FIGURE 20-2. Sample focus patient care notes.

For Mr. **Baron**, the nurse may use focus charting to document specific aspects of teaching related to the colonoscopy and postprocedural care. In addition, because of the effects of anesthesia from the colonoscopy procedure, Mr. Baron may not completely remember all that is taught. Therefore, the nurse documents to include the patient's wife in the discharge teaching to ensure that the information taught was indeed understood. Remember that Mrs. Baron is a nurse. Her clinical knowledge and any necessary reinforcement of information would also be documented.

Charting by Exception

Charting by exception (CBE) is a shorthand method of documenting normal findings, based on standardized normals, standards of practice, and predetermined criteria for assessments and interventions. Significant findings or **exceptions** to the predefined norms are only documented in detail. CBE is common on EHRs. Many patient examination findings are completed by health care providers using checklists and checkboxes on EHRs, instead of fully written descriptions.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

When a health care provider charts by exception, it means that only exceptions to normal findings are documented. If nothing is documented the patient's status is assumed to match the normal findings established for the data.

For example, on a pulmonary exam, the normal finding may be clear breath sounds at 12 to 20 breaths per minute. Providers who find this on examination of the patient do not need to chart this in CBE. However, if the patient had a respiratory rate above or below the normal or had clear lung sounds with occasional wheezes, the provider would need to clearly document this. However, these lung sounds can go undocumented in CBE, since the majority of breath sounds were clear. Nuances and subtleties found on examination can easily go undocumented.

Benefits of CBE have been noted to be less time needed for charting (freeing more time for direct patient care), a greater emphasis on significant data, easy retrieval of significant data, timely bedside charting, standardized assessment, greater interdisciplinary communication, better tracking of important patient responses, and lower costs (King et al., 2014; Nguyen et al., 2014).

However, there are drawbacks to CBE. Distinctive findings on examination of the patient can go undocumented. In CBE, the clinical portrayal of the patient is based on a standardized checklist of normal findings rather than full descriptions of examination findings. A lack of detail in documentation can compromise patient safety and place the health care provider in legal jeopardy. A patient's medical record is expected to accurately reflect the complete description of distinctive findings and details discovered on patient examination. A chart that is missing pertinent information could fail to draw attention to potential problems. In addition, nurses' notes with few explanations, little description of key findings, or no mention of periodic patient checks could be construed as negligence by a plaintiff's attorney guided by the premise, not charted, not done (Brown, 2016; Nursing Service Organization [NSO], 2020).

Case Management Model

Managed care's emphasis on quality, cost-effective care delivered within a limited time frame has led to the development of interdisciplinary documentation tools that clearly identify those outcomes that select groups of patients are expected to achieve on each day of care. The case management model promotes collaboration, communication, and teamwork among caregivers; makes efficient use of time; and increases quality by focusing care on carefully developed outcomes. One limitation of this model, however, is that it works best for "typical" patients with few individualized needs. At present, there is little consensus about which documentation tools are best for recording routine aspects of care and avoiding repetition.

COLLABORATIVE PATHWAYS

Collaborative pathways—also called **critical pathways** or care maps—are used in the case management model. The collaborative pathway specifies the care plan linked to expected outcomes along a timeline. In some documentation systems, the collaborative pathway is part of a computerized documentation system that integrates the collaborative pathway and documentation flow sheets designed to match each day's expected outcomes. CBE is frequently used with collaborative pathway documentation systems.

OCCURRENCE CHARTING

When a patient fails to meet an expected outcome or a planned intervention is not implemented in the case management model, this variance from the plan is documented. The usual format for **occurrence charting** or **variance charting** is the unexpected event, the cause of the event, actions taken in response to the event, and discharge planning, when appropriate. The variances most likely to be documented are those that affect quality, cost, or length of stay.

Consider **Millie Delong**, the woman who developed a wound infection. Typically, after abdominal surgery, infection is a complication, not a normal or expected occurrence. Therefore, using the case management model, the nurse needs to document this unexpected outcome with variance charting.

Formats for Nursing Documentation

When the nursing process is fully implemented, nursing documentation in the patient's permanent record includes the following formats.

Initial Nursing Assessment

A typical electronic form used to record the initial database obtained from the nursing history and physical assessment is

illustrated in Chapter 15. Accurate documentation of these data is important to provide a baseline for later comparisons as the patient's condition changes.

Think back to **Jason Chandler**, the adolescent brought to the ED in police custody. Owing to the nature of the admission, a complete nursing assessment would be inappropriate. However, the nurse needs to thoroughly assess the patient for signs and symptoms indicating problems associated with swallowing the package of drugs. Later, once the initial situation is resolved, an initial history and physical examination would be performed.

Care Plan

Patient records must communicate the patient's problems or diagnoses; related goals, outcomes, and interventions; and progress or resolution of the problems. The nursing care plan may be written separately or incorporated into a multidisciplinary plan. In a traditional nursing care plan, nursing diagnoses, goals and expected outcomes, and nursing interventions are written for each patient (see the sample student plan in Chapter 17 and the care plans at the end of each clinical chapter). Standardized care plans may also be used that identify common problems and related care for select patient groups. These generally incorporate standards of high-quality care, but unless such care plans are individualized, they may not sufficiently address individual patient needs. Formats for care plans vary greatly.

Patient Care Summary

The patient care summary contains an overview of valuable patient information such as documentation, lab and test results, orders, and medications. Figure 20-3 shows one such example.

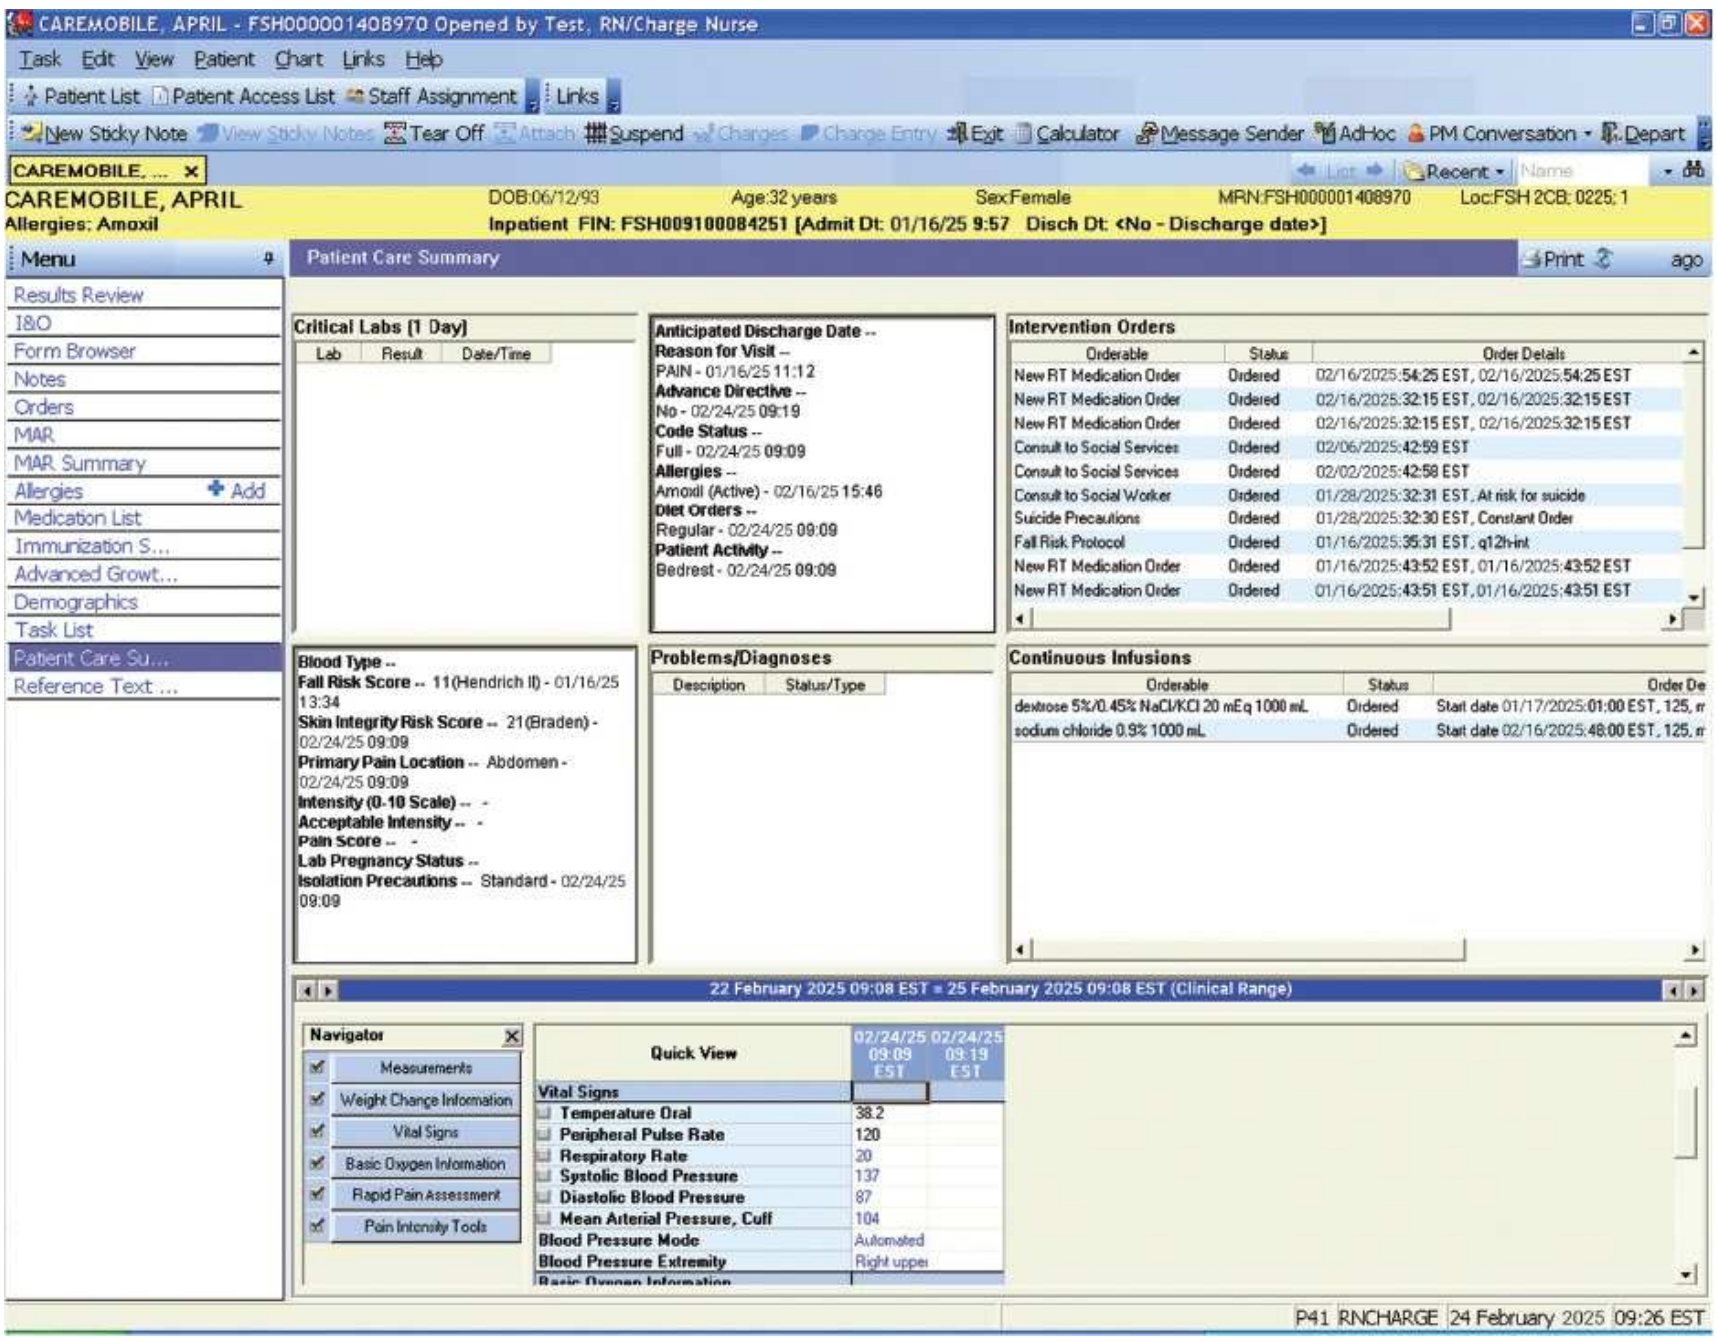

FIGURE 20-3. Electronic patient care summary.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Critical/Collaborative Pathways

The case management plan is a detailed, standardized care plan that is developed for a patient population with a designated diagnosis or procedure. It includes expected outcomes, a list of interventions to be performed, and the sequence and timing of those interventions. The critical/collaborative pathway is an abbreviated summary of key information taken from the more detailed case management plan.

Progress Notes

The purpose of progress notes is to inform caregivers of the progress a patient is making toward achieving expected outcomes. The method used to record the patient's progress depends on the documentation system being used. Common examples include narrative nursing notes, SOAP notes, PIE notes, focus charting, CBE, and the case management model. Figure 20-4 shows an example of a home hospice nurse's charting following a home visit.

Flow Sheets and Graphic Records

Flow sheets are documentation tools used to efficiently record routine aspects of nursing care (Fig. 20-5). Well-designed flow sheets enable nurses to quickly document the routine aspects of care that promote patient goal achievement, safety, and well-being. The **graphic record** is a form used to record specific patient variables such as pulse, respiratory rate, blood pressure readings, body temperature, weight, fluid intake and output, bowel movements, and other patient characteristics.

A graphic record would be used for both **Millie Delong** and Phillippe Baron, described at the beginning of the chapter. Specifically for Ms. Delong, documentation of vital signs is significant because she has a wound infection. Because Mr. Baron is post colonoscopy, his vital signs also need to be assessed frequently. In addition, fluid intake and output are key postoperative assessment findings to be documented.

Medication Administration Records

The patient's medication record must include documentation of all the medications administered to the patient (drug, dose, route, time), the nurse administering the drug, and, for some medications (e.g., analgesics), the reason the drug was administered and its effectiveness. Some electronic medication administration records (eMARs) allow providers to look up detailed information about a medication's indications, contraindications, expected and adverse effects, and safe dosage ranges. Sample medication records are shown in Chapter 30.

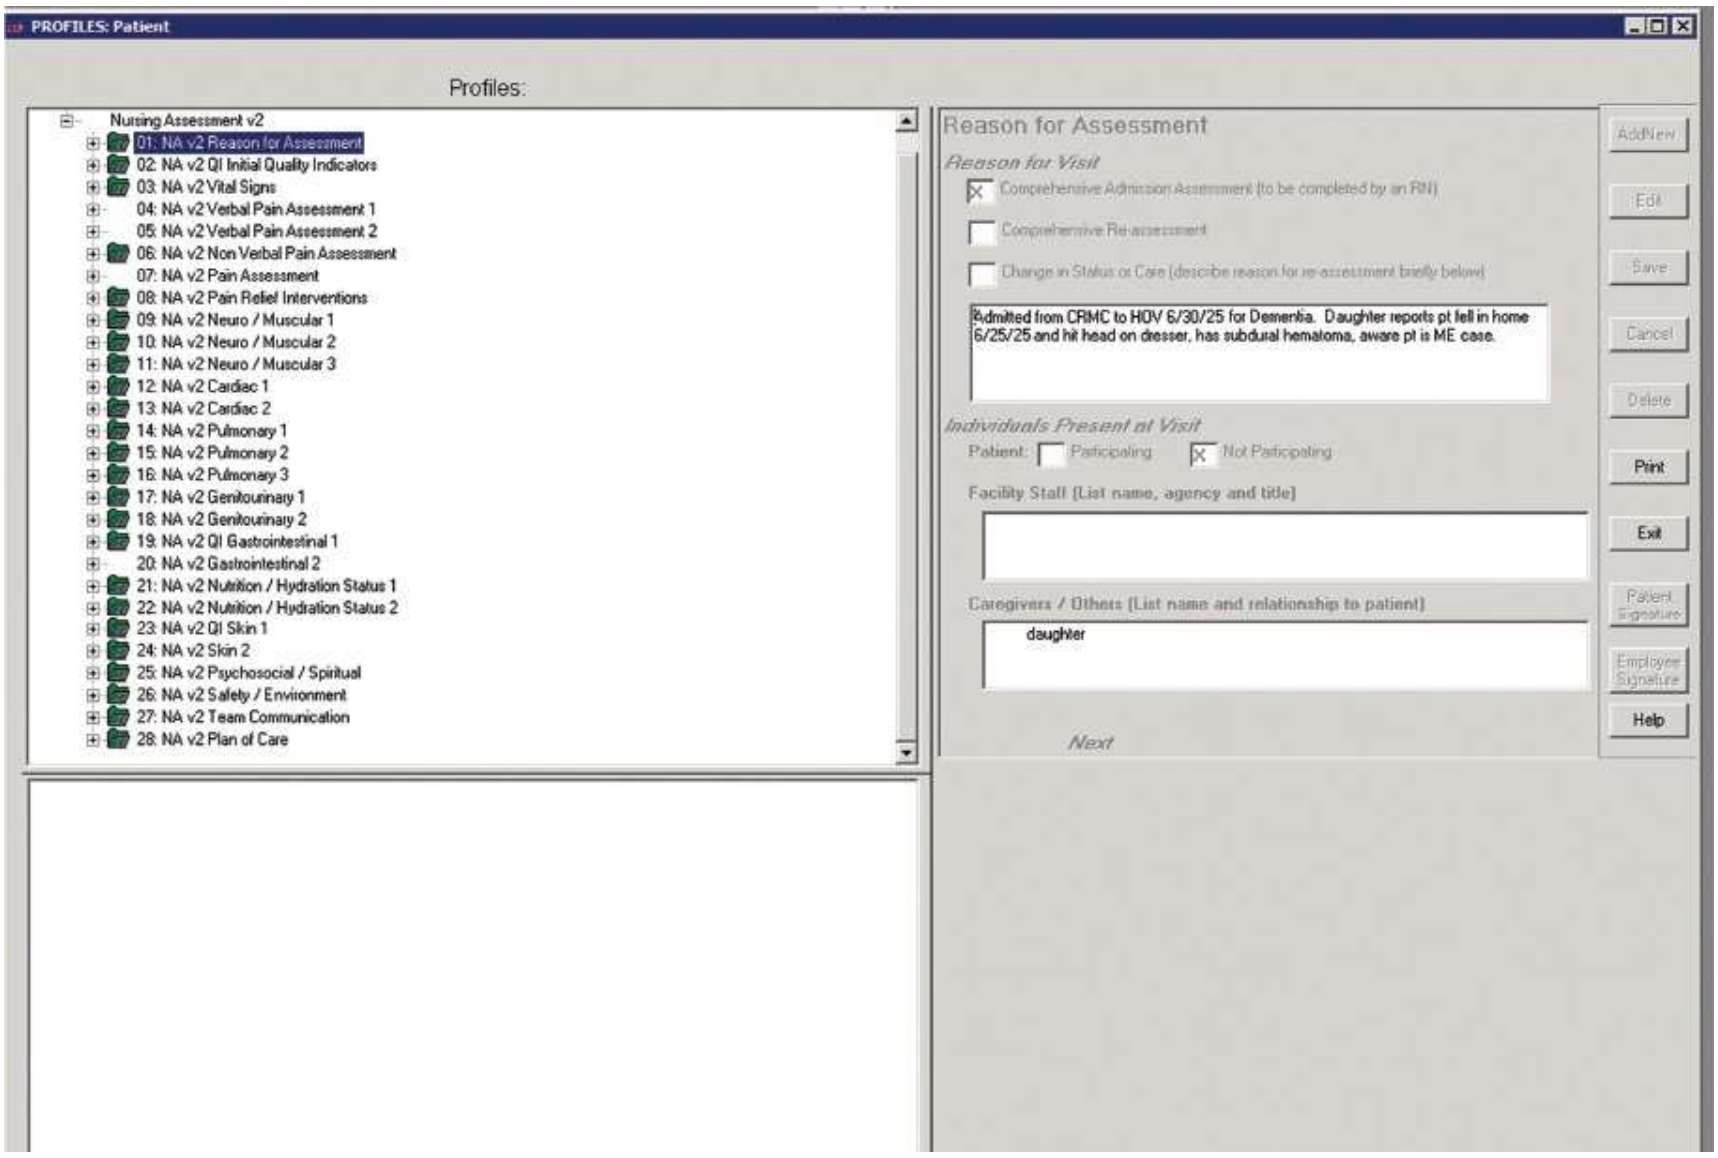

FIGURE 20-4. Electronic nursing documentation following a home hospice visit. (Used with permission. Forms completed with fictitious data.)

Acuity Records

Twenty-four–hour reports are increasingly used in conjunction with acuity reports, with which nurses rank patients as high-to-low acuity in relation to both the patient's condition and need for nursing assistance or intervention. A trauma patient whose condition is changing rapidly and who requires intensive nurse monitoring and intervention merits a higher acuity rank than a patient whose condition is stable. Acuity rankings are often used to determine staffing requirements. A nursing unit with patients with higher acuity rankings requires more professional nurses than a unit with the same number of patients who have lower acuity ranks.

Discharge and Transfer Summary

When a patient is discharged from care or transferred from one unit, institution, or facility to another, a **discharge summary** should be written that concisely summarizes the reason for treatment, significant findings, the procedures performed and treatment rendered, the patient's condition on discharge or transfer, and any specific pertinent

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

instructions given to the patient and family. The EHR often prepares these forms electronically. You can imagine how frustrating it would be for patients and their family caregivers to arrive in a new treatment setting and have to inform professional caregivers about their needs because the care plan didn't accompany them. Review the discharge instructions in Chapter 12.

Consider **Phillippe Baron**, the man who had undergone a colonoscopy. The nurse is responsible for completing the discharge summary, making sure to include specific aspects of self-care teaching and both the patient's and wife's understanding of the teaching.

Home Health Care Documentation

Documentation of home health care visits that reports the patient's progress serves multiple purposes. Sent to the attending health care provider with a request for signed medical orders to continue treatment, these records ensure continuity of care. Sent to third-party payers, they establish the need for continuing home care with continued reimbursement for necessary services. Medicare, for example, reviews progress summaries to determine whether a patient meets one of these Medicare requirements:

- The patient is homebound and still needs skilled nursing care.
- Rehabilitation potential is good.
- The patient's status is not stabilized.
- The patient is dying.
- The patient is making progress in expected outcomes of care.

The **Outcome and Assessment Information Set (OASIS)** is a group of data elements that:

- represent core items of a comprehensive assessment for an adult home care patient.
- form the basis for measuring patient outcomes for purposes of outcome-based quality improvement (OBQI).

The OASIS is a key component of Medicare's partnership with the home care industry to foster and monitor improved home health care outcomes (see https://edit.cms.gov/files/document/draft-oasiseall-items-instrument-02012022.pdf). Overall, the OASIS items are useful for outcome monitoring, clinical assessment, care planning, and other internal facility-level applications. OASIS data items encompass sociodemographic, environmental, support system, health status, and functional status attributes of (nonmaternity) adult patients. In addition, selected attributes of health service use are included. See Chapter 12 for a sample home health certification and a skilled nursing note.

Long-Term Care Documentation

Documentation in long-term care settings is specified by the Resident Assessment Instrument (RAI), which helps staff gather definitive information on a resident's strengths and needs and addresses these in an individualized care plan. The RAI helps staff track changes in a resident's status by evaluating resident goal achievement and making appropriate revisions in the care plan. The goal is to coordinate the efforts of the multidisciplinary team to ensure that residents achieve the highest level of functioning possible (quality of care) and maintain their sense of individuality (quality of life).

The RAI consists of four basic components:

- **Minimum data set**: A core set of screening, clinical, and functional status elements that form the foundation of the comprehensive assessment of all residents in long-term care facilities certified to participate in Medicare or Medicaid. The items in the minimum data set standardize communication about resident problems and condition.
- Triggers: Specific resident responses for one or a combination of minimum data set elements that identify residents who either have or are at risk for developing specific functional problems and who require further evaluation using resident assessment protocols.
- Resident assessment protocols: Structured, problem-oriented frameworks for organizing minimum data set information and examining additional clinically relevant information about a resident. Resident assessment protocols help identify social, medical, nursing, and psychological problems and form the basis for individualized care planning.
- Utilization guidelines: Specified in state operation manuals that direct when and how to use the RAI.

Statutory law, federal regulations, and the Health Care Financing Administration specify how the RAI is implemented. A RAI must be completed for residents of Medicare skilled nursing facilities or Medicaid nursing facilities, hospice residents, and short-term stay or respite residents who reside in a facility for longer than 14 days.

Benefits of using the RAI process include the following:

- Residents respond to individualized care.
- Staff communication becomes more effective.
- Resident and family involvement increases.
- Documentation becomes clearer.

REPORTING CARE OR REQUESTING ACTION

To report is to give an account of something that has been seen, heard, done, or considered. Reporting is the oral, written, or computer-based communication of patient data to others. A laboratory report, for example, might communicate to the health care team that a patient's cardiac enzymes are normal or that a biopsy of breast tissue revealed malignant or atypical cells. A nurse's shift or handoff report or nursing note might communicate the progress a patient is making toward goal achievement. Nurses commonly have to consult a physician or nurse practitioner about a patient situation which requires a report and action. Common methods for reporting among health practitioners, in addition to the patient record, include face-to-face meetings, telephone conversations, fax documents, messengers, written messages, audiotaped messages, and computer messages. Each of these methods has certain benefits and limitations, as detailed in Table 20-4.

Table 20-4 Common Methods of Communication Among Health Care Professionals

METHOD	ADVANTAGES	DISADVANTAGES
Face-to-face meeting	• Message can be delivered immediately. • Nonverbal messages are readily conveyed. • Message can be clarified; receiver's questions can be raised and answered.	• Both the communicating and the receiving people must be available at the same time, in the same place. • Ordinarily, there is no permanent record for later use.
Faxed documents	• Message can be delivered in short time. • Graphic images can be sent. • Paper record is available. • Validation by sender possible.	• Requires fax telephone number and fax machine by both sender and receiver. • Requires time to transmit across telephone system which can be busy and not immediately transmitted. • Complete confidentiality not possible.
Telephone or video conferencing	• Message can be delivered immediately. • Message can be clarified; receiver's questions can be raised and answered. • Two parties need not be present in same place.	• Only the tone of voice and voice inflections can be communicated—no nonverbal messages unless video conferencing method or some other real-time conferencing means are used.
Written message	• Message can be exchanged at times convenient for the people involved. • Record is available. • Time efficient if message is understood.	• Message usually cannot be validated with the sender.
Audiotaped message	• Message can be exchanged at times convenient for the people involved. • Record is available. • Time efficient if information communicated is complete.	• Message usually cannot be validated with the sender.
Computer message	• Message can be delivered immediately —even to those at a great distance. • Parties need not be present in same place. • Two-way communication is possible by e-mail. • Record is available. • Many people can participate in exchange.	• No nonverbal messages can be communicated. • Privacy concerns remain an issue.

To ensure patient safety, the Institute for Healthcare Improvement (www.ihi.org) 2021 promotes the SBAR (or ISBAR) communication technique as a framework for communication between members of the health care team about a patient's condition (see http://www.ihi.org/resources/Pages/Tools/SBARToolkit.aspx):

- **I**dentity/**I**ntroduction: Communicate who you are, your credentials, your relationship to the patient, where you are, and why you are communicating.
- **S**ituation: Communicate concisely what is occurring in the patient situation and why you are consulting the health care provider—what is happening.
- **B**ackground: Explain significant details of the patient's history related to the current situation—brief patient information.
- **A**ssessment: Give your analysis of the current situation—what you think.
- **R**ecommendation: Explain the action requested or the health care provider's recommendation regarding the current situation—what you want.

Note that there are different ISBAR formats: earlier versions used simply SBAR, and some newer versions use ISBARR, with the last R being a read-back of orders/response. See Chapters 8 and 12 for more on ISBAR and other frameworks for patient handoffs. ISBAR or SBAR is an easy-to-remember, concrete mechanism useful for framing any conversation between two health care providers regarding a patient situation. It is useful when one clinician is requesting another clinician's immediate attention and action. It allows for an easy and focused way to set expectations for what will be communicated, and how, between members of the team, which is essential for developing teamwork and fostering a culture of patient safety. For example, it is a communication framework that should be used when a nurse is requesting the consultation and action of a physician regarding a patient situation.

QSEN TEAMWORK AND COLLABORATION

Open communication, mutual respect, and shared decision making are all essential to achieving quality patient care. Practice using an approved patient handoff until you become proficient in reporting off to a colleague.

Many students find collaborative communication with health care providers about patient conditions challenging and intimidating. See Box 20-6 (on page 540) for suggestions about how to do this well. Be professional whenever making a report about care or requesting a consultation. Ensure that you have all the pertinent data, and be concise. Most importantly, keep the report focused on the patient. The communication should be objective and brief. It should never involve gossip, floor politics, or any social commentary. It is never professional to speak disrespectfully about a patient or family; such comments reflect negatively on you and may negatively impact patient care.

Box 20-6 ISBARR Report to a Health Care Provider

Before calling the health care provider:

1. Assess the patient.
2. Review the record for the appropriate health care provider to call.
3. Know the admitting diagnosis.
4. Read the most recent physician and nursing notes.
5. Have the record at hand and be ready to report allergies, medications, IV fluids, and lab and test results.
6. Every **ISBARR** report is different. Focus on the problem. Be concise. Not everything in the following outline needs to be reported—just what is needed for the situation.

I Identity/Introduction	State NAME, TITLE, and UNIT	"I am Ellen McLoughlin, a nursing instructor from Georgetown University precepting a nursing student, working on 3 Main."
S Situation	I am calling about: (Patient Name and Room Number) The PROBLEM I am calling about is:	"I am calling about Ms. Miriam Klein, room 9. She is scheduled this morning for a prophylactic bilateral mastectomy to prevent breast cancer but she is now having second thoughts."
B Background	State Admission Diagnosis and Admission Date	"Ms. Klein was admitted yesterday. She has a strong family history of

	State Pertinent Medical History Brief synopsis of Treatment if pertinent Most recent Vital Signs Changes in VS or Assessment from prior assessment	breast and ovarian cancer. She tested positive earlier this year for BRCA1 (breast cancer gene). She signed the informed consent for the mastectomy in your office and had all her preop testing done, but she has been up all night expressing second thoughts."
A Assessment	Give your analysis and conclusions about the present situation. Words like "might be" or "could be" are helpful. A diagnosis is not necessary. If the situation is unclear, at least try to indicate what body system might be involved. State how severe the problem seems to be. If appropriate, state that the problem could be life threatening.	"This seems to be more than the usual presurgery anxiety. She has clearly stated that she regrets signing the informed consent and wishes to withdraw her consent."
R Recommendation	Say what you think would be helpful or needs to be done (medications, treatment, tests, x-rays, EKG, CT, transfer to critical care, health care provider evaluation, consultant evaluation). Ask about any Changes in Orders	"Shall I hold the preop orders and notify the OR that we need to place the surgery on hold until you can see her and determine if she wants this done?" "Is there anything else I can do at this time?"
R Read-back	Restate orders you have been given. Clarify how often to do vital signs. Under what circumstances to call back.	"I understand you want me to hold the preop medications and call the OR to place the surgery on hold. Thank you. I will tell her that you should be here within the hour."

Note: Be sure to document the change in condition and the health care provider notification.

Change-of-Shift/Handoff Reports

A **change-of-shift report** or **handoff** is given by a primary nurse to the nurse replacing them, or by the charge nurse to the nurse who assumes responsibility for continuing care of the patient. The change-of-shift report may be given in written form or orally in a meeting (Fig. 20-6), or it may be audio- or videotaped. The trend today is toward a standardized, streamlined shift report system at the bedside—the **bedside report** (see Chapter 8). Vital elements of the bedside report include the oncoming and outgoing nurse assessing the patient together, reviewing medication records and the health care provider's and nursing orders, and establishing patient goals for the shift. The AHRQ identifies the goal of the nurse bedside report strategy as helping to ensure the safe handoff of care between nurses by involving the patient and family. It is the patient who defines who is family and who can participate in the report. Evidence demonstrates that the bedside shift report can improve patient safety and quality, the patient experience of care, nursing staff satisfaction, and time management and accountability between nurses (Fig. 20-7). Some nurses prefer to restrict the handoff to two nurses in a private environment free from distraction and interference.

FIGURE 20-6. During a change-of-shift report, a nurse from the ending shift provides a summary of the patient's condition and current status of care to the nurse coming on duty. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

Bedside Shift Report Checklist

- ❑ Introduce the nursing staff to the patient and family. Invite the patient and family to take part in the bedside shift report.
- ❑ Open the medical record or access the electronic work station in the patient's room.
- ❑ Conduct a verbal SBAR report with the patient and family. Use words that the patient and family can understand.
  - **S** = **Situation.** What is going on with the patient? What are the current vital signs?
  - **B** = **Background.** What is the pertinent patient history?
  - **A** = **Assessment.** What is the patient's problem now?
  - **R** = **Recommendation.** What does the patient need?
- ❑ Conduct a focused assessment of the patient and a safety assessment of the room.
  - Visually inspect all wounds, incisions, drains, IV sites, IV tubings, catheters, etc.
  - Visually sweep the room for any physical safety concerns.
- ❑ Review tasks that need to be done, such as:
  - Labs or tests needed
  - Medications administered
  - Forms that need to be completed (e.g., admission, patient intake, vaccination allergy review, etc.)
  - Other tasks: _____
- ❑ Identify the patient's and family's needs or concerns.
  - Ask the patient and family:
    - *"What could have gone better during the last 12 hours?"*
    - *"Tell us how your pain is."*
    - *"Tell us how much you walked today."*
    - *"Do you have any concerns about safety?"*
    - *"Do you have any worries you would like to share?"*
  - Ask the patient and family what the goal is for the next shift. This is the patient's goal — not the nursing staff's goal for the patient.
    - *"What do you want to happen during the next 12 hours?"*
    - Follow up to see if the goal was met during the verbal SBAR at the next bedside shift report.

FIGURE 20-7. Bedside shift report checklist. (*Source:* From Agency for Healthcare Research and Quality. https://www.ahrq.gov/sites/default/files/wysiwyg/professionals/systems/hospital/engagingfamilies/strategy3/Strat3_Tool_2_Nurse_Chklst_508

Typical information shared among nurses, patients, and families in a change-of-shift report includes the following:

- Basic identifying information about each patient: name, room number, bed designation, diagnosis, and attending and consulting health care providers
- Current appraisal of each patient's health status:
  - Changes in patient's status during your shift and the patient's response to nursing and medical therapy
  - Pertinent monitoring, lab, and radiology data; data that are irregular or data that have been noted to be irregular in the past and have now been resolved
  - Abnormal findings in your physical or head-to-toe assessment
  - Patient progress in regard to diagnoses/health problems and goal achievement
  - Pain level and pain management needs
- Current orders (especially any newly changed orders):
  - Changes in medications, intravenous fluids, diet, toileting, and activity level
  - Upcoming or ongoing tests and procedures, and specific instructions for these such as NPO after midnight
- Abnormal occurrences during your shift
- Any unfilled orders that need to be continued onto the next shift
- Patient and family questions, concerns, and needs
- Reports on patients who have been transferred or discharged

Telephone/Telemedicine Reports

Telephones and telemedicine equipment can link health care professionals immediately and enable nurses to receive and give critical information about patients in a timely fashion. For example, the hematology lab may call to report a dangerously low platelet count, and the nurse may in turn call the attending health care provider to obtain new medical orders. When reporting significant changes in a patient's condition to health care providers and other health care professionals, be prepared to do the following:

- Identify yourself and the patient, and state your relationship to the patient. (Example: "Dr. Gomez-Lobo, this is Laura Bishop, case manager with St. Mary's Home Health Care. I'm calling about Mr. John Clouser, a patient of yours who was just discharged home following a workup for recurrent chest pain.)
- Report concisely and accurately the change in the patient's condition that is of concern and what has already been done in response to this condition. (Example: "When I first arrived in his home, he was complaining of feeling dizzy, and his blood pressure was 190/110. Yesterday morning in the hospital, it was 150/90. His wife appears anxious and says she doesn't know how she is going to take care of him. I had him rest for 30 minutes, and when I checked his pressure again it was 186/110.")
- Report the patient's current vital signs and clinical manifestations.
- Have the patient's record at hand to make knowledgeable responses to any health care provider's inquiries. In examples given above, the health care provider would probably want to know all the vital signs and might ask questions about the treatment regimen, both in the hospital and upon discharge.
- Concisely record the time and date of the call, what was communicated to the health care provider, and the health care provider's response. Read back any changes to the orders.

Transfer and Discharge Reports

Nurses report a summary of a patient's condition and care when transferring patients from one unit, institution, or facility to another (e.g., from the postanesthesia care unit to a surgical floor) and when discharging patients. The nurse making the report should concisely summarize all the patient data that caregivers need to provide immediate care. See Chapter 12 for transfer and discharge reporting guidelines.

Reports to Family Members and Significant Others

Nurses play a crucial role in keeping the patient's family and significant others updated about the patient's condition and progress toward goal achievement. Always clarify with the patient which visitors, if any, are entitled to progress reports —for example: "Mrs. Neale, do you object to our disclosing your health information to family or friends?" It is necessary to ask the patient which specific family members and/or significant others have permission to receive information, and this should be documented. Similarly, clarify what types of information may be communicated, and be familiar with facility policy about such communications. Some facilities provide family members approved by the patient a "code" to use when calling the facility to ask about the patient's condition. If the patient objects to disclosure, nurses are not permitted to discuss the patient's health condition with family or friends.

If a patient is not able to communicate objections, such as in an emergency situation or when unconscious, professional caregivers must use their best professional judgment to decide whether to talk to family and friends. Procedural outcomes should be reported to the patient by the health care provider who performed the procedure. For example, the nurse is generally not the caregiver who informs family members that a patient's biopsy has revealed a malignancy. The nurse does, however, often explain what this will mean for the patient after the family has this information. Information should be shared in a manner that is honest, compassionate, and respectful of the person's ability to understand medical concepts.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Incident Reports

An **incident report**, also termed a **variance report** or occurrence report, is a tool used by health care facilities to document unexpected events that result in, or have the potential to result in, harm to a patient or person or damage property. An incident report should be filed whenever an unexpected event occurs. These reports are used for risk management and quality improvement and are not intended to be used for disciplinary action against staff members. Incident reports improve the management and treatment of patients by identifying high-risk patterns so that staff development programs can be initiated to prevent future problems. These forms also make all the facts about an incident available to the facility in case of litigation.

You should be familiar with facility policy about your responsibilities and obligations if involved personally in an incident that results in, or has the potential to result in, harm to a patient, employee, or visitor, or if you witness such an incident. An example of an incident report form and a fuller discussion of this topic appear in Chapter 7.

CONFERRING ABOUT CARE

To **confer** is to consult with someone to exchange ideas or to seek information, advice, or instructions. A nurse may confer with another nurse, such as when a primary care nurse consults with a nurse clinical specialist about a particular patient's care. A nurse may consult a physician or nurse practitioner about treatment plans for a hospitalized patient. A school nurse may confer with a child's teacher or a psychologist about a behavior problem. A community health nurse and a health care provider may confer about a patient's activity regimen. Health practitioners also confer with each other to validate information. Health care professionals increasingly use electronic support groups to consult with clinicians who share similar interests or who have expertise in other specialty areas. See Box 20-7 for an illustration of how one health care system is using creative conferrals to motivate change in contemporary nursing practice and nursing care delivery.

Think back to **Jason Chandler**, the adolescent who was brought into the ED by the police. He was refusing treatment. To determine the legal implications of administering treatment to the patient, the health care provider consulted the hospital's attorney for legal guidance. Doing so helped to clarify which actions were and were not acceptable.

Consultations and Referrals

When nurses detect problems they cannot resolve because the problems are outside the scope of independent nursing practice or the nurses' expertise, they consult with or make referrals to other professionals. The process of inviting another professional to evaluate the patient and make recommendations to you about the patient's treatment is called a **consultation**. The EHR may be designed to automatically initiate nursing consults to selected services based on what you document. For example, if you click on the "yes" box when answering the question, "Does the patient have financial concerns regarding hospitalization?" a nursing consult may be automatically sent to the social work department.

The process of sending or guiding the patient to another source for assistance is called a **referral**. A patient may be referred by a hospital to a community health nursing service for assistance with home care. A school nurse may refer a student to a hospital ED. A community health nurse who learns that a patient with multiple sexual contacts is HIV positive will refer to the Department of Health for tracking of these contacts.

Box 20-7 **Delivering Optimal Care to Patients and Their Families**

Nursing leadership at MedStar Health is committed to leading the organization along a path to a clearly defined goal: the delivery of optimal care to patients and their families. To guide these efforts, the MedStar Way, a set of activities, has been devised to motivate change in contemporary nursing practice and nursing care delivery.

1. Senior Leader Rounding—to promote communication and access within the nursing team
2. Multidisciplinary Team Rounding—to ensure consistent documentation and timely communication, and discuss the care plan

3. Nurse Leader Rounding—to support a culture of service, assess patient and staff needs, and promote the patient/family experience
4. Nursing Staff Hourly Rounds—to anticipate and evaluate patient needs, and improve safety and satisfaction
5. Nurse-to-Nurse Bedside Shift Reports—to ensure safe handoffs, and keep the patient and family involved in the care plan
6. Huddles at the Beginning of Each Shift—to improve teamwork and communication, and ensure timely response to issues and concerns
7. White Boards in Patient Rooms—to encourage communication, teamwork, and efficiency, and to assure the patient that the team is working together to provide optimal care
8. Post-discharge Phone Calls—to ensure quality clinical outcomes and increase patient satisfaction

Source: Reprinted with permission. (2013, June). The MedStar Way: Delivering optimal care to patients and their families. *MedStar Nursing Insights and Innovations*, *1*(2), 7.

Most health facilities have policies for referrals. A facility may use a special form for making referrals. Referral policies usually indicate who may initiate a referral, how it is to be done, and so on. Referrals are especially important for providing continuity of care for people who need a variety of services. The health practitioners to whom a patient is referred must receive the information that is most useful to the continuity of care. The key question is, "What would I want to know about this patient if I were the person who would be continuing their care?" The patient must know and approve of a referral to another facility or to other health personnel.

Before requesting a consultation or making a referral, determine which profession has the needed expertise and which of its practitioners is appropriate for consultation or referral. A great disservice is done to patients when referrals are poorly made. Patients and family members also appreciate a phone number and practical tips about how to easily reach the referred practitioner.

Recall **Millie Delong**, the woman with the wound infection. Obtaining a consultation from a wound, ostomy, and continence nurse may be appropriate to assist with measures for wound care. Additionally, consultation with an infection-control nurse may be necessary if the patient's wound remains infected or fails to heal.

Nursing and Interdisciplinary Team Care Conferences

Nurses and other health care professionals frequently confer in groups to plan and coordinate patient care. Such conferences are also used for instructing students and practitioners. A nursing care conference is a meeting of nurses to discuss some aspect of a patient's care. For example, several nurses who are caring for a generally uncooperative patient may initiate a conference. This would allow each nurse an opportunity to offer their opinion about the patient's problem and its cause, and then together they could discuss possible solutions to the problem.

Nurses may invite other health care practitioners to a nursing care conference concerning a patient's care. For example, in the Jason Chandler scenario, a clinical psychologist may be invited to address the possibility that a mental disorder is influencing this patient's behavior.

Nursing Care Rounds

Nursing care rounds are procedures in which a group of nurses visit selected patients individually, at each patient's bedside. The primary purposes of nursing care rounds are to gather information to help plan nursing care, to evaluate the nursing care patients have received, and to provide patients with an opportunity to discuss their care with those administering it. As each patient is visited, the nurse assigned provides a short summary of the patient's nursing diagnoses and goals and the care being given. Nurses may also make rounds with health care providers to share nursing's perspective with them.

Nursing care rounds have two principal advantages over discussions in a meeting room: Nursing personnel can actually see the patient as a report of care is given, and the patient and family can participate in discussions of patient-centered care. Nurses should use language the patient can understand when holding discussions at the bedside. Otherwise, the patient is likely to feel excluded and cannot intelligently participate in the discussion.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Purposeful Rounding

Purposeful rounding is a proactive, systematic, nurse-driven, evidence-based intervention that helps nurses anticipate and address patient needs (McLeod & Tetzlaff, 2015). Although nurses may struggle to reorganize their day to permit hourly rounding, it is difficult to dismiss the growing body of research that suggests effective, purposeful rounding can promote patient safety, encourage team communication, and improve staff ability to provide efficient patient care. Nurses at Stanford Health Care identified eight behaviors of purposeful rounding, which are listed in Table 20-5. Be sure to note their recommendation to use the recommended key phrase before leaving a patient room, "Is there anything else I can do for you before I go? I have time."

Research on hourly rounding in 14 hospitals revealed dramatic improvements:

- 12% increase in patient satisfaction scores
- 52% reduction in patient falls
- 37% reduction in call light use
- 14% decline in skin breakdowns

In addition, one hospital measured a 20% reduction in the distance walked each day by the nursing staff (Stanford Health Care, n.d.).

Table 20-5 Eight Behaviors of Purposeful Rounding

BEHAVIOR	EXPECTED RESULTS
Use Opening Key Words: Greet the patient and review the plan of care for the day.	Reduces anxiety, contributes to efficiency
Accomplish scheduled tasks.	Contributes to efficiency
Address four Ps: pain, personal needs (toileting), positioning, fall prevention.	Quality indicators, pain management, decubitus, and fall prevention
Address additional personal needs, questions.	Nurse-sensitive indicators: care and respect, listening
Conduct environmental assessment: bed alarms, IV pumps, hats, urinals.	Contributes to efficiency, safety, teamwork and addresses patient satisfaction
Ask "Is there anything else I can do for you before I go? I have time."	Increases efficiency, improves communication and teamwork (respect, caring, listening)
Tell each patient when you will be back.	Contributes to efficiency, provides reassurance
Document the round.	Quality and accountability

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in documenting your nursing care and reporting to colleagues, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

- Does your documentation today leave a complete, accurate, concise, current, timely, factual, and organized record of your nursing care?
- How easy was it for you to know what to chart, when to chart, and where? Are you confident that you followed your facility's protocols?
- Are you becoming sufficiently comfortable working with medical terminology? Are your words spelled correctly? Did you use only acceptable abbreviations?
- Are you able to find the information you need to know about your patient in the paper or electronic health record?
- Are you comfortable and confident both giving and receiving reports about your patient? Are you proficient in bedside reports and patient handoffs?
- Are you becoming skilled in purposeful rounding?

The cultivation of skill in documenting nursing care and reporting to colleagues is a critical component of professional nursing. Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to address their

activity needs? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Interview three practicing nurses and ask them to describe the documentation methods they have used in their practice. Which methods did they prefer? Which method was most effective, time efficient, and easiest to use?
. A nurse overhears you complaining about writing narrative nursing notes and says to you, "Don't sweat it. I never worry about documentation—it's a waste of time. I'd rather spend my time doing things for patients than writing up what I did." Think about what you would like to say to this nurse and your rationale for this. Ask other students for their response, and compare your answers.
. Imagine that you are a nurse in a long-term care facility, and that you and the facility are being sued for negligence by the family of an older resident who fell and fractured her hip last year. You know the resident but do not remember much about the day she fell. What data do you hope to find recorded in her health record? Which documentation system would most likely provide the type of information you think you need to reconstruct the events surrounding her fall?
. How would you respond to each of the following requests for patient information? Compare your responses with those of another student and talk about any differences.

- The mayor of your town, who is up for reelection, was just admitted to your unit after an acute myocardial infarction. You receive a phone call from his office requesting information about his condition.
- A woman you have never seen approaches you in the hallway, identifies herself as a close friend of a married male patient on your unit, and requests information about his condition.
- A case manager from a managed care organization calls you to ask about the progress an older surgical patient is making postoperatively. You have heard that the organization is eager to discharge her quickly, and you feel uncomfortable reporting any information over the phone.
- A family member asks your advice about developing a PHR. She says she has heard that there are privacy concerns. How do you respond?

PRACTICING FOR NCLEX

. A nurse is caring for a postoperative patient who has a prescription for morphine 2 mg IV every 3 hours. Which examples documenting pain management best reflect recommended guidelines? Select all that apply.

a. 6/12/25 0945 Morphine 2 mg administered IV. Patient's response to pain appears to be exaggerated. M. Patrick, RN.
b. 6/12/25 0950 Morphine 2 mg administered IV. Patient appears to be comfortable. M. Patrick, RN.
c. 6/12/25 1015 Administered morphine 2 mg IV at 0945, patient reporting pain as 2 on a scale of 1 to 10. M. Patrick, RN.
d. 6/12/25 0945 Patient reports severe pain in right lower quadrant. M. Patrick, RN
e. 6/12/25 0945 Morphine IV 2 mg will be administered to patient every 3 hours. M. Patrick, RN
f. 6/12/25 0945 Patient states they do not want pain medication despite return of pain. After discussion, patient agrees to try morphine 2 mg IV. M. Patrick, RN

. When documenting a dressing change to a residual right limb, the nurse erroneously documents that the dressing change was performed on the left leg. How will the nurse most appropriately correct the documentation?

a. Use white correction fluid to cover the error and neatly write over the correction
b. Draw a single line through the error, write "mistaken entry," add correct information, and date and initial
c. Blacken out the error with permanent marker and rewrite the note in the next available space
d. Leave the entry in place, create a correctly written entry below, and cite the charting error above

. A patient being discharged from the hospital asks to receive a copy of their medical record. What information will the nurse give the patient?

a. "I'm sorry, but patients are not allowed to copy their medical records."
b. "I can make a copy of your record for you right now."
c. "You can read your record while you are still a patient, but copying records is not permitted according to HIPAA rules."
d. "I'll check with the medical records department to determine how you request a copy."

. A graduate nurse and preceptor are discussing protected health information (PHI) and HIPAA laws. The preceptor explains that PHI can be released without the patient's signed authorization in which situations? Select all that apply.

a. News media are preparing to report on a patient who is a public figure.
b. Data are needed for the tracking and notification of disease outbreaks.
c. Protected health information is needed by a coroner.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

d. Child abuse and neglect are suspected.
e. Protected health information is needed to facilitate organ donation.
f. The sister of a patient with Alzheimer's disease wants to help provide care.

. A nurse receives a call from a friend requesting information on her mother-in-law who was just admitted to the hospital. How does the nurse best respond?
a. "You shouldn't be asking me to do this. I could be fined or lose my job for disclosing this information."
b. "I'm sorry; per privacy laws, I can't give out patient information—even to my best friend or a family member."
c. "Because of HIPAA, you could get in trouble for asking for this information unless you are authorized by the patient to receive it."
d. "Why are you asking? Are you extremely worried?"

. A nurse receives a prescription for an analgesic for a patient who has compound fractures of the tibia and fibula. What schedule will the nurse use to administer the medication?
Electronic health record (EHR)
Health care provider order sheet
8:00 AM: Hydromorphone 1 mg IV every 2 hours PRN severe pain. –S. Jones, MD
a. When the patient requests it
b. Every 2 hours on the even hours
c. Daily, every 2 hours
d. As requested, 2 hours or more after the last dose

. A health care provider has been urgently paged to another unit and asks a nurse to enter a pain medication prescription for their patient in the electronic medical record. Which response by the nurse is most appropriate?
a. "Thank you for taking care of this; I'll be happy to enter a verbal order into the electronic health record."
b. Get a second nurse to listen to the order, write the order on the health care provider order sheet, and ensure both nurses sign it.
c. "I'm sorry; verbal orders can only be accepted in an emergency. Please enter this quickly before leaving this unit."
d. Try calling another resident for the order or wait until the next shift.

. A nurse is looking for trends in a postoperative patient's vital signs. In which part of the electronic health record will the nurse find this information?
a. Admission sheet
b. Admission nursing assessment
c. Progress notes
d. Graphic record

. A nurse is using the PIE format to document care of a patient who is diagnosed with type 2 diabetes. What information does the nurse need to complete documentation in this format?
a. Patient problem list
b. Narrative notes describing the patient's condition
c. Overall trends in patient status
d. Planned interventions and patient outcomes

. A nurse uses the ISBARR format to report the deteriorating mental status of a patient using morphine via a patient-controlled analgesia pump (PCA) for postoperative pain. Place the following nursing statements related to this call in the correct ISBARR order.
a. "I am calling about Mr. Sanchez in Room 202 who is receiving morphine via a PCA pump for pancreatic cancer."
b. "Mr. Sanchez has been difficult to arouse, and his mental status has declined over the past 12 hours."
c. "You want me to discontinue the PCA pump until you see him tonight at patient rounds."
d. "I am Rosa Clark, an RN working on the second floor of South Street Hospital."
e. "Mr. Sanchez was admitted 2 days ago following a diagnosis of pancreatic cancer."
f. "I suggest a decrease in the dose of morphine."

. A new home health nurse and preceptor are reviewing charting for a patient with advanced lung cancer who receives Medicare benefits. When reviewing a draft of the new nurse's documentation, which statement will the preceptor correct?
a. Explained to family that irregular respirations or agitation may occur when the patient is actively dying
b. Patient seemed in better spirits and reported going out for ice cream with his family yesterday
c. Stage 3 pressure ulcer dressing on sacral area is dry and intact; due to be changed tomorrow
d. Performed medication reconciliation with focus on pain management and anticoagulation

. The nurse on an oncology unit is caring for a patient admitted for dyspnea and wheezing. What is most important for the nurse to include in the change-of-shift report to the oncoming nurse?

a. Partial bath was given
b. Patient received physical therapy
c. CT scan revealed a mass in the right lung
d. Patient did not eat lunch today

ANSWERS WITH RATIONALES

. **c, d, f.** The nurse should enter information in a complete, accurate, concise, current, and factual manner, indicating the date and both the time the entry was written and the time of pertinent observations and interventions. When charting, the nurse should avoid the use of stereotypes, derogatory terms, and judgments such as "response to pain appears to be exaggerated" or "seems to be comfortable." Stating that medication will be given does not document care given; this prescription/intervention belongs in the plan of care.

. **b.** The nurse should not black out, use erasers or correcting fluids to correct documentation, or remove a page with an error and rewrite the data on a new page. To correct an error after it has been entered, the nurse should mark the entry "mistaken entry," add the correct information, and date and initial the entry. If the nurse records information in the wrong chart, the nurse should write "mistaken entry—wrong chart" and sign off. The nurse should follow similar guidelines in electronic records.

. **d.** According to HIPAA, patients have a right to view and receive a copy of their health record; update their health record; get a list of the disclosures a health care institution has made, independent of disclosures made for the purposes of treatment, payment, and health care operations; request a restriction on certain uses or disclosures; and choose how to receive health information. The nurse should be aware of facility policies regarding the patient's right to access and copy records.

. **b, c, d, e.** According to HIPAA, a health institution may share PHI without written patient authorization for tracking disease outbreaks, infection control, statistics related to dangerous problems with drugs or medical equipment, investigation and prosecution of a crime, identification of victims of crimes or disaster, reporting incidents of child abuse, neglect or domestic violence, responding to a valid subpoena, and providing information needed by coroners, medical examiners, funeral directors, and law enforcement in the case of a death from a potential crime and for facilitating organ donations. The nurse does not provide information to a news reporter without the patient's express authorization; typically, a hospital representative communicates with the media. A patient who has Alzheimer's disease will still need a release to share information; this may be given by the power of attorney.

. **b.** The nurse should immediately clarify they must adhere to HIPAA laws to protect patient privacy and confidentiality. Mentioning penalties for breaches of privacy sidesteps the need to clearly introduce or reinforce the policy. It may be appropriate to ask the friend about her concerns, only after clarifying privacy laws.

. **d.** PRN means "as needed." The nurse teaches the patient that the medication may be requested every 2 hours to treat pain. If pain occurs before 2 hours elapses, the nurse provides comfort measures and collaborates with the health care provider for a change in prescription.

. **c.** In most facilities, health care providers may only issue verbal orders in an emergency. The provider is present but finds it impossible, due to the situation, to write or enter the order in the electronic health record. Calling another health care provider or waiting until the next shift would be inappropriate; the patient should not have to wait for the pain medication, and a provider is available who can quickly write/enter the order.

. **d.** While one set of vital signs may appear on the admission nursing assessment, the best place to find sequential recordings demonstrating a pattern or trend is the graphic record. The admission sheet and flow sheet do not include ongoing vital sign documentation.

. **a.** In the PIE format, patient problems are numbered; documented in the progress notes; worked up using the Problem, Intervention, Evaluation (PIE) format; and evaluated each shift. Resolved problems are dropped following the nurse's review. Narrative notes allow nurses to describe a condition, situation, or response in their own terms. Overall trends in patient status can be seen immediately when using charting by exception (CBE). Planned interventions and patient-expected outcomes are the focus of the case management model.

. **d, a, e, b, f, c.** The order for ISBARR is: Identity/Introduction, Situation, Background, Assessment, Recommendation, and Read-back.

. **b.** To receive Medicare services, the patient must be homebound, still needs skilled nursing care, or that the patient is dying, among others. Leaving the home for ice cream may interfere with home care benefits.

. **c.** The nurse's shift or handoff report includes basic identifying information about the patient. The outgoing nurse includes the patient's current health status and changes during their shift, response to nursing and medical therapy, pertinent monitoring and assessment findings (e.g., lab and radiology data), pain management, changes in orders (medications, intravenous fluids, diet, and rationale), upcoming/ongoing tests and procedures, and instructions for these, such as NPO after midnight, unfilled prescriptions for the next shift to follow up on, and patient and family

Informatics and Health Care Technologies

Frank Albrecht

Frank is a 72-year-old patient who has chronic obstructive pulmonary disease. His wife, who has been his primary caregiver since his diagnosis 5 years ago, died last year and he now lives alone in their original two-level family home. He has been sleeping on the couch in the living room because he can no longer go upstairs. He has a daughter who lives across country who tries to get home once a month to be sure he has food and medications. Not surprisingly, Frank has had four hospital readmissions in the past year.

Jorge Bobadilla

Jorge is the nurse manager on an orthopedic unit where the majority of patients are older and have had knee or hip replacements. Some have difficulty urinating after surgery and many have urinary catheters placed. Some are admitted to the hospital from nursing homes and have had indwelling urinary catheters for weeks. Jorge's unit is being watched closely for its high incidence of catheter-associated urinary tract infections (CAUTIs). Jorge wants help to monitor this problem.

Danielle Smith

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Danielle is a new nurse manager on a neurology intensive care unit. She has a passion for palliative care and knows that many intensive care unit patients and families would benefit greatly from timely referrals to palliative care so that appropriate treatment goals could be identified, and distressing symptoms addressed.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe nursing informatics and its contributions to nursing and quality health care.
. Describe how the system development lifecycle (SDLC) process can be used to ensure the successful implementation of a new electronic health record (EHR).
. Define terms basic to informatics: system usability, system optimization, standard technologies, interoperability, and security and privacy of electronic data.
. Describe the two types of nurse informaticists and the responsibilities of each.
. Describe how telehealth, telemedicine, and telecare are helping people achieve their health goals. What are the advantages of each?
. Describe how using telehealth, remote monitoring, and mobile care teams, hospital-at-home programs can deliver quality inpatient care in the comfort of one's home.

telehealth
telemedicine
usability

Technology in health care is now pervasive. Nurses in all types of care settings are interacting with increasing numbers of information and communications technologies and medical devices to aid in care delivery. The need for nurses trained in informatics to ensure optimized and evidence-based use of these devices and clinical information systems continues to grow. Nurses understand clinical workflows and how care is delivered, giving them the knowledge needed to help design technologic tools and **clinical information systems** that will support and transform health care. A clinical information system is a computer-based system designed for collecting, storing, manipulating, and making available clinical information important to the health care delivery process.

With an estimated 3.9 million nurses in the United States, all interacting with technology, it is important to ensure that all nurses possess a foundational understanding of how systems work and the concepts that allow for knowledgeable questioning and ongoing innovation. This chapter will help you develop an understanding of the concepts that are essential to nursing informatics (NI) practice; knowledge of these concepts will provide a sound framework to improve health care technologies with input from nurses who actually use the device or system. This chapter also covers emerging informatics trends that will need nursing input as they evolve into quality tools that drive clinical, administrative, and even financial outcomes.

HISTORY OF NURSING INFORMATICS

The science of **informatics** drives innovation that is defining future approaches to information and knowledge management in biomedical research, clinical care, and public health. Although seemingly of recent origin, at its core, informatics has been around for centuries. Many have asserted that the first informatics nurse (IN) was Florence Nightingale, who compiled and processed data to improve sanitation conditions in military hospitals during the Crimean War in the 1850s (Betts & Wright, 2006).

Informatics has come to represent a growing field with a focus on the use of technology and data to improve patient care. The American Nurses Association (ANA) recognized NI as a specialty and developed board certification in 1992. Several disciplines (nursing, medicine, pharmacology, nutrition, and dentistry) have developed informatics expertise within their respective domains, each adding their skills and knowledge to a dynamic field.

The importance of informatics nursing has been highlighted with the widespread implementation of the electronic health record (EHR), a digital version of a patient's chart or medical history. Informatics is not just about the EHR, though. Many areas within the scope of informatics deal with areas such as telehealth, mobile devices, patient portals, data analytics, and technologies for educating nurses in academic settings and for conducting research.

The need for expertise in the field of informatics has undoubtedly increased since the signing of the American Reinvestment and Recovery Act (ARRA) in 2009. The ARRA included the authorization of the Health Information Technology for Economic and Clinical Health (HITECH) Act, which allocated billions of dollars to stimulate the adoption of quality **health information technology (IT)** systems or EHRs that demonstrate **meaningful use** (ONC, 2009). HealthIT.gov defines meaningful as using certified EHR technology to:

- Improve quality, safety, efficiency, and reduce health disparities
- Engage patients and family
- Improve care coordination and population and public health
- Maintain privacy and security of patient health information

Ultimately, it is hoped that the meaningful use compliance will result in:

- Better clinical outcomes
- Improved population health outcomes
- Increased transparency and efficiency
- Empowered people
- More robust research data on health systems

Meaningful use regulations set specific objectives that eligible professionals (EPs) and hospitals must achieve to qualify for Centers for Medicare & Medicaid Services (CMS) Incentive Programs.

The percentage of hospitals with certified EHR technology increased from 72% to 97% between 2011 and 2014. In 2015, nearly 9 in 10 of office-based physicians (87%) had adopted an EHR system, up from 42% in 2008 (Charles et al., 2015; ONC, 2015a). Much of the focus of informatics work between 2003 and 2013 revolved around the EHR in the inpatient setting, but with changing payment models and care delivery systems consolidating and converging, informatics practice has begun to migrate outside the walls of the hospital and infiltrate new areas of practice.

CHALLENGE TO INTELLECTUAL AND ETHICAL SKILLS

I am a Critical Care Nurse Practitioner on a neuro intensive care unit in a university medical center. Because of an interest in palliative care and personal experience of the benefits that accompany early palliative care consults in intensive care units, I am growing more and more concerned with the failure of our staff to initiate consults to palliative care for our critically ill neuro patients with problematic symptoms. Neurocritical illness creates an unpredictable hospital course and many different opinions on a patient's prognosis. Many of our patients suffer permanent disability and with some diagnoses morality rates are above 50%. Palliative care could dramatically increase the well-being of our patients and their families. Sadly, too few of our physicians and nurses are familiar with palliative care and many confuse a referral to palliative care with "giving up" on a patient. Many of our surgeons believe they have an obligation to "rescue" our patients and even when the prognosis is grim, they may continue to order inappropriate life-sustaining/death-prolonging interventions. The medical director of our unit is not a fan of palliative care.

Thinking Outside the Box: Possible Courses of Action

- Accept the status quo and realize that I may just be ahead of my time. In no way do I want to be a martyr for the cause.
- Start trying to win over my colleagues one by one to value palliative care and hope that palliative care referrals increase.
- Educate my colleagues on how to use a validated screening tool to identify patients appropriate for palliative care consults and begin to measure how appropriate palliative care consults relate to length of stay, patient satisfaction/engagement scores, and in-hospital costs.

Evaluating a Good Outcome: How Do I Define Success?

- Our neuro patients and their families get the highest-quality care including timely referrals to appropriate palliative care.
- My ethical integrity is intact, and I am an effective advocate for our patients.
- I don't rock the boat and get our surgeons angry with me.
- I learn how to use data to bring about needed change.
- Staff learn how to use, and are comfortable using, a standardized screening tool to identify patients who would benefit from a palliative care referral. Our informaticists make this tool available electronically.

Personal Learning: Here's to the Future!

Luckily at the same time I was experiencing this challenge I enrolled in a Doctor of Nursing Practice (DNP) program where I learned how to use research to bring about system-wide change. It wasn't an easy journey and there were many obstacles, but I am happy to report that our unit will be examining ways to customize a screening tool that can be standardized for palliative care screenings with each patient admitted to the neuro ICU. Ideally our palliative care consults will increase threefold. I am definitely feeling good about my ability to improve the quality of care for our patients and families.

Danielle McCamey Smith, MS, CRNP, ACNP-BC Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your competencies for professional practice? Can you think of other ways to respond? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients?

Patient-Centered Care: How can you motivate your physician and nurse colleagues to sufficiently value person-centered care to learn more about palliative care and its benefits for your patient population? Similarly, how can you get your colleagues to invest in learning how to use a standardized palliative care screening tool and your institution to use the EHR to facilitate appropriate consults to palliative care?

Teamwork and Collaboration/Quality Improvement: How did you identify potential allies for the change you wished to create and work with barriers to changing the status quo?

Safety/Evidence-Based Practice: What research was most persuasive in getting staff "on board" for change? How did your research project findings support the need for change and convince administration

that your proposal was sound and worth the investment of people and resources?

Informatics: What role might a nurse informaticist have played in bringing about needed change? What else might the nurse have done to ensure a successful outcome?

NURSING INFORMATICS DEFINED

The ANA published the Nursing Informatics Scope of Practice in 1994, followed by Standards of Practice in 1995. Combined and updated versions were published in 2001, revised in 2008 and again in 2015 (ANA, 2015). This document contains standards of professional practice and competencies for INs in 16 categories of informatics practice, each including criteria that describe the expected knowledge, skills, and abilities necessary to meet each standard. Each of these categories supports nursing care delivery and evaluation of care using technology and associated analytics. These 16 areas are summarized in Table 21-1 (on pages 553–554).

The ANA defines **nursing informatics (NI)** as "the specialty that integrates nursing science with multiple information management and analytical sciences to identify, define, manage, and communicate data, information, knowledge, and wisdom in nursing practice. NI supports nurses, consumers, patients, the interprofessional health care team, and other stakeholders in their decision making in all roles and settings to achieve desired outcomes. This support is accomplished through the use of information structures, information processes, and information technology" (ANA, 2015, p. 1). See Figure 21-1. The American Medical Informatics Association (AMIA), which represents multiple disciplines in the field of informatics, defines NI as "the science and practice that integrates nursing, its information and knowledge, with information and communication technologies to promote the health of people, families, and communities worldwide" (AMIA, 2009). To put it simply and broadly, NI ensures that information used by nurses supports improvement in patient care delivery.

In addition to these definitions, nursing theorists introduced a classic NI framework. In the 1980s, Graves and Corcoran described the concepts of data, information, and knowledge as key components of NI practice. These components, each building on the next, lay the foundation for informatics in terms of how technology and clinical systems are used to continually advance care delivery and improve clinical outcomes. Taking individual data elements and combining them to provide meaningful information that leads to knowledge and enhanced patient care delivery is the essential premise of this framework. In the 2008 revision of the Informatics Scope and Standards, an additional concept, "wisdom," was added to reflect the appropriate use of knowledge (ANA, 2015; Topaz, 2013). Box 21-1 describes each of the components that provide the underpinnings for informatics practice. To read more about nursing informatics check out the American Nurses Informatics Association website (https://www.ania.org/) and the Healthcare Information and Management Systems Society, Inc. (HIMSS) website (https://www.himss.org/resources/what-nursing-informatics).

Box 21-1 Informatics Scope and Standards Definitions: "DIKW"

Data: Discrete entities that are described without interpretation
Information: Data that have been interpreted, organized, or structured
Knowledge: Information that is synthesized so that relationships are identified
Wisdom: Appropriate use of knowledge to manage and solve human problems

NURSING INFORMATICS EDUCATION

The ANA differentiates two types of nurse informaticists: the information nurse (IN) and the informatics nurse specialist (INS). The IN is a registered nurse with an interest or experience in an informatics field. This may be a nurse who has assisted with the implementation of an EHR and is considered a "superuser," with training being primarily on the job. Superuser is a term frequently used when describing someone who has become a system expert and can navigate the EHR with ease as they enter and review patient data. An INS is a registered nurse with formal graduate-level education in the field of informatics. The INS is often responsible for strategy development, implementation, and maintenance and evaluation of clinical systems requiring collaboration with multiple disciplines (ANA, 2015).

To educate these nurse specialists, universities began offering graduate education in NI, first at the University of Maryland and the University of Utah beginning in the 1980s. More than 40 NI graduate programs are now available across the United States, including several that are available completely online. NI education typically consists of a master's degree program, although some universities offer a post-master's program for those who already possess another graduate nursing degree.

Table 21-1 ANA Informatics Competencies

STANDARDS OF PRACTICE AREA	STANDARD	EXAMPLES OF COMPETENCIES
1. Assessment	The informatics nurse collects comprehensive data, information, and emerging evidence pertinent to the situation.	Uses evidence-based assessment technologies, instruments, tools, and effective communication strategies in collecting pertinent data to define the issue or problem Uses workflow analysis to examine current practice, workflow, and the potential impact of an informatics solution on that workflow
2. Diagnosis, problems, and issues identification	The informatics nurse analyzes assessment data to identify diagnoses, problems, issues, and opportunities for improvement.	Uses standardized clinical terminologies, taxonomies, and decision support tools, when available, to identify problems, needs, issues, and opportunities for improvement
3. Outcomes identification	The informatics nurse identifies expected outcomes for a plan individualized to the health care consumer or the situation.	Defines expected outcomes in terms of the health care consumer, health care worker, and other stakeholders, and their values, ethical considerations, and environmental, organizational, or situational considerations
4. Planning	The informatics nurse develops a plan that prescribes strategies, alternatives, and recommendations to attain expected outcomes.	Develops a customized plan considering clinical and business characteristics of the environment and situation Integrates current scientific evidence, trends, and research into the planning process
5. Implementation	The informatics nurse implements the identified plan.	Partners with the health care consumer, health care team, and others, as appropriate, to

		implement the plan on time, within budget, and within the plan requirements
5a. Coordination of activities	The informatics nurse coordinates planned activities.	Organizes components of the plan Provides leadership in the coordination of the information technology and health care activities for integrated delivery of efficient and cost-effective health care services
5b. Health teaching and health promotion	The informatics nurse employs informatics solutions and strategies for education and teaching to promote health and a safe environment.	Integrates informatics solutions, resources, ergonomics, and disability adaptations into clinical practice workflow and patient care routines
5c. Consultation	The informatics nurse provides consultation to influence the identified plan, enhance the abilities of others, and effect change.	Synthesizes data, information, knowledge, theoretical frameworks, and evidence when providing consultation
6. Evaluation	The informatics nurse evaluates progress toward attainment of outcomes.	Conducts a systematic, ongoing, and criterion-based evaluation of the outcomes in relation to the structures and processes prescribed by the project plan and indicated timeline
7. Ethics	The informatics nurse practices ethically.	Uses Code of Ethics for Nurses with Interpretive Statements (ANA, 2015) Employs informatics principles, standards, and methodologies to establish and maintain health care consumer confidentiality within legal and regulatory parameters
8. Education	The informatics nurse attains knowledge and competence that reflect current nursing and informatics practice.	Participates in ongoing education to advance their knowledge base and professional practice Shares educational findings, experiences, and ideas with peers
9. Evidence-based practice and research	The informatics nurse integrates evidence and research findings into practice.	Uses data to communicate evidence to promote effective care processes and decisions Uses the skills and tools available to the informatics nurse for research studies
10. Quality of practice	The informatics nurse contributes to quality and effectiveness of nursing and informatics practice.	Demonstrates quality by documenting the application of the nursing process in a responsible, accountable, and ethical manner, and by facilitating a unified or defined level of documentation by

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		nurses in clinical practice Analyzes quality data to identify opportunities to improve nursing and informatics practice or outcomes
11. Communication	The informatics nurse communicates effectively in a variety of formats in all areas of practice.	Supports communication preferences of health care consumers, families, and colleagues Communicates strategies to improve and enhance the value of documentation
12. Leadership	The informatics nurse demonstrates leadership in the professional practice setting and the profession.	Promotes the organization's vision, the associated goals, and the strategic plan Mentors colleagues for the advancement of nursing informatics practice, the profession, and quality health care
13. Collaboration	The informatics nurse collaborates with the health care consumer, family, and others in the conduct of nursing and informatics practice.	Partners with others to effect change and produce positive outcomes through the sharing of data, information, and knowledge of the health care consumer or situation
14. Professional practice evaluation	The informatics nurse evaluates their own nursing practices in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations.	Supports delivery of appropriate care and services in a culturally, ethically, and developmentally sensitive manner Interacts with peers and colleagues to enhance their own professional nursing practice or role performance
15. Resource utilization	The informatics nurse employs appropriate resources to plan and implement informatics and associated services that are safe, effective, and fiscally responsible.	Monitors the health care information needs of individual consumers and communities, as well as the available operational and technical enterprise resources to achieve desired outcomes
16. Environmental health	The informatics nurse supports practice in a safe and healthy environment.	Promotes a practice environment that reduces ergonomic and environmental health risks for workers and health care consumers Assists in the development of health and safety alerts within the clinical documentation and technology solutions

NURSING INFORMATICS PRACTICE

The field of nursing has a wide variety of specialties, one of which is informatics. Even within the field of informatics there are multiple areas of practice where nurses can focus their work. Typically, an IN will have primary responsibilities in one of the areas described in the following sections but may be knowledgeable in many.

Nurses practicing in direct care roles should have general knowledge of these areas of informatics practice at a conceptual level to ensure efficient, effective, and safe use of clinical information systems and other technologies. A basic understanding of these concepts will also help nurses participate and collaborate in the required and ever-evolving interdisciplinary work of embedding technology into care delivery to drive improvement. The following sections describe several nurse informatics practice concepts and areas of practice, all essential for the effective use of technologic tools.

SYSTEM DEVELOPMENT LIFECYCLE

A fundamental framework for nurse informaticists in any care setting is the **system development lifecycle (SDLC)**. The concepts or phases of the SDLC are very similar to the concepts of the nursing process but with an informatics or technology focus. While for a practicing nurse, the areas of Assess, Plan, Implement, and Evaluate make up the foundational concepts of care, the SDLC requires focus in the areas of Analyze and Plan, Design and Build, Test, Train, Implement, Maintain, and Evaluate. A brief description of each phase of the SDLC follows.

QSEN INFORMATICS

Nurses who will be using a clinical information system should be involved in all phases of the SDLC to ensure the best chance that the system will meet its intended need.

Analyze and Plan

Before considering the employment of any type of new technology or an update to a system already in place, analysis and planning must take place. Questions need to be answered, such as:

- What is the purpose of this new technology or change to the current technology?
- What problem do we hope to solve?
- What data do we have to indicate the current state of the issue (how bad is the problem)?
- How will its use be incorporated into the current workflow of the nurse?
- Will it streamline nursing documentation, or will it increase the burden of documentation?
- Will it improve the overall usability and experience with the EHR?
- What technologic options are available if there are more than one?

Often this step is not given the necessary attention; well-intentioned people may go straight to the technologic solution without a thorough analysis of the actual need. In this phase of the SDLC, it is imperative to understand the organizational need and provide the supporting baseline data to justify the effort (Sengstack, 2016). Tools and resources used during this phase may include need assessment tools, data analytics programs, or workflow diagrams (Ozkaynak et al., 2016). During this phase, nurses can help to clarify the need and provide expertise in the current workflow.

Recall the example above, in which **Danielle**, the new nurse manager was concerned about patient's receiving appropriate and timely palliative care. During this phase, Danielle would be instrumental in working with the informatics team to help understand the problem and explore potential solutions.

Design and Develop

Once thorough planning and analysis has resulted in an identified need for a new technology or an enhancement to a current system, the more granular work of designing begins. A basic tenet for informatics success is that nurses and other care providers using the clinical information system must be involved in the design for successful outcomes to be achieved (St. John, 2015).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Danielle would be integral in helping the interdisciplinary team to design the best technical solution to support an improved process. With Danielle on the design team, all aspects of appropriate patient identification and subsequent follow-up actions could be addressed.

Questions asked during this phase may include:

- What should the screen display look like? How should it be laid out to be consistent with other screen layouts?
- Can the design support or improve the nurse's workflow as mapped out during the analysis and planning phase?
- Is there evidence supporting the effectiveness of the new technology and, if so, does it provide recommendations for the design?
- Can we use standard nursing terminology in the electronic system to better capture nursing's contribution to care delivery and patient outcomes?

Test

Testing of technology has several phases.

Technology Alert

Thorough testing helps to avoid unexpected issues (some of which can affect patient safety), since technology is complex with multiple interrelated components. A change or update to one part of a clinical information system, such as an EHR, can have effects on other areas not initially identified.

As part of the implementation for any new technology, or even a small change to a current EHR, an overall testing plan is developed that includes the use of testing scripts. These test scripts, ideally developed in collaboration with nurses who will be using the technology, ensure that all components of the system are working as designed and will support workflow during interaction with the system (Carlson, 2015). While testing is typically carried out by informatics specialists experienced in the testing of systems, the nurses using the system should provide input into the testing scripts and participate in user acceptance testing.

In our scenario, **Danielle** would be able to provide the essential components of test scripts to ensure that the new system updates are working as designed before they are built into the live system.

The phases of testing with brief descriptions are listed in Table 21-2.

Table 21-2 Technology Testing Phases

TESTING PHASE	WHEN PERFORMED	DESCRIPTION
Unit testing	During design and development	This is basic testing that occurs initially. • Do the screens contain the right information? • Was anything left out? • Is everything in the right place on

		the screen? • Are there any typos?
Function testing	After unit testing is complete	Uses test scripts to validate that a system is working as designed for *one* particular function. For example: • The EHR system sends a lab order to the lab system on the day they are scheduled 6 hours in advance. • The EHR system sets any order that has been active for over 365 days to a status of “auto-complete.”
Integration testing	After function testing is complete	Uses test script to validate that a system is working as designed for an entire workflow that integrates multiple components of the system. For example: All steps in an EHR work as designed from order entry to administration of a medication (including the proper functioning and communication between order entry screens, the pharmacy system and the medication administration record).
Performance testing	After integration testing	Performance testing is more technical and ensures proper functioning of the system when there are high volumes of end users or care providers using the system at the same time. Can it handle the load?
User acceptance testing	After all testing above	An important final phase of testing where the nurse (or other system end user) test drives the new system or new functions of the EHR to ensure it’s working as designed.

Source: From Carlson, S. (2015). Testing in the healthcare informatics environment. In P. Sengstack & C. Boicey (Eds.). *Mastering informatics: A healthcare handbook for success*. Sigma Theta Tau International Honor Society of Nursing (Sigma). Adapted and reprinted with permission of Sigma Theta Tau International Honor Society of Nursing (Sigma).

Train

Effective end-user training is a key element to an implementation’s success. EHRs are complex and multifaceted. They have linkages that require end users to negotiate between different areas of the chart that can be confusing. While training end users effectively often takes a backseat to more visible activities like system configuration, it can make or break an implementation. Poor training can produce decreased efficiency, staff turnover, patient care errors, and poor-quality documentation followed by decreased billing revenue (Kulhanek, 2015).

The type of training required depends on the implementation project. For the installation of a new EHR, a classroom model of education will most likely be needed. If you are adding only a new module to a current system, web-based or online training may be adequate. If the change is a simple addition to current functionality, a tip sheet or just-in-time training may suffice. An organization’s informatics training team should use principles of adult learning theory along with a framework, such as the five steps of ADDIE—analysis, design, development, implementation, and evaluation—in

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the training development process. The development of training materials needs nursing input to ensure that the technology supports nursing processes and workflows that will enable nurses to navigate the system as easily as possible (Kulhanek, 2015).

Implement

Implementation refers to the activities surrounding the activation of the new technology, or "flipping the switch" to begin using the new functionality in the EHR. The planning for this phase includes ensuring all testing has been completed, end users have been educated, and support resources are ready for any questions that arise (Houston, 2015). Nurse superusers are often employed during this implementation phase to assist if help is needed.

Maintain

Once a new technology is up and running, the maintenance phase begins. Many think that the most difficult work is behind them at this point; however, this next phase can be just as, if not more challenging than, previous phases. Keeping a system up and running requires ongoing allocation of resources and attention to detail (Settergren, 2015). A few of the tasks that occur during the maintenance phase for an EHR include:

- Ongoing updates to hospital and ambulatory order preference lists
- Ongoing updates to hospital and ambulatory medication preference lists
- Ongoing updates to provider patient lists
- Ongoing updates to scheduling blocks (ambulatory, radiology, and procedure areas)
- Monthly loads (new medications, medication pricing, and clinical alerts)
- Error work queue maintenance (e.g., billing errors, sure script errors, many types of interface errors)
- Pricing updates
- Quality measures updates
- Clinical decision support tools/rules
- Monthly updates from EHR vendor

Evaluate

The acquisition and management of EHRs represent a significant portion of an organization's financial bottom line. Millions of dollars are invested in these systems, not just to meet meaningful use objectives for the financial incentive, but to provide a higher quality of care than paper and pencil probably could. Once implemented, administrators across the nation are asking, "Is our EHR helping us realize our organizational goals? Is it reducing medication errors? Is it eliminating duplicate ordering of diagnostic testing? Is it allowing more time for our care providers to spend with the patients? Is it improving the overall health of our patients?" With expertise, guidelines, and tools still emerging in this area, organizations are beginning to address the evaluation of health IT. Evaluation may be the last phase of the SDLC, but it represents an essential step for nurses to be involved in before circling back to Assess and Plan based on the results of the evaluation (Sengstack, 2015).

This would also be one of the most important phases for **Danielle** in our continued example. Are patients now receiving appropriate and timely palliative care? With the significant investment of the team's time to develop the new system functionality, it would seem that this is something Danielle should ensure happens.

See Table 21-3 (on page 558) for an example of the steps that should be taken when evaluating the effectiveness of the technology.

INFORMATICS CONCEPTS

The field of informatics possesses a unique body of knowledge and often uses terms that are not commonly part of typical health care interactions or communication. These terms—*usability, optimization, standard terminologies, interoperability*, and *security and privacy*—represent core concepts in the implementation and maintenance of clinical information systems. The discussion of these terms and concepts that follows is intended to heighten awareness among practicing nurses so that they can ask questions and use systems safely, and so that improvements can continue to be

made to all technologies.

System Usability

The National Institute of Standards and Technology defines **usability** as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" (NIST, 2017). EHRs and order entry systems are complex. Sometimes the way screens are formatted can be confusing, making it a real challenge to perform nursing tasks in a way that makes sense. The Healthcare Information and Management Systems Society (HIMSS) Electronic Health Record Usability Task Force report cited that usability was perhaps the most important factor that hindered the widespread adoption of EHRs prior to the signing of the HITECH Act in 2009 (Belden et al., 2009). Making clinical systems easy to use, intuitive, and supportive of nurses' workflow is what usability is all about. A system with effective usability can save time, reduce errors, and improve end user satisfaction (St. John, 2015). That is why it is so important to include nurses who will be using the technology in the planning and design phases of the SDLC.

Comprehensive tools for usability evaluation can be found through a number of sources both internal and external to the health care IT industry. The HIMSS EHR Usability Task Force (2009) supports the usability principles described in Box 21-2 (on page 559). These principles may seem foundational or simply common sense, but they are essential in the effective designing of safe, high-quality clinical information systems.

System Optimization

Once an EHR or other clinical information system is in use, and as nurses and other care providers become more proficient with the system, the need for improvements to better support and improve care delivery will usually become evident. Definitions of EHR **optimization** vary, but commonly include strategies to improve processes, maximize effective use, reduce errors, reduce costs, eliminate workflow inefficiencies, improve clinical decision support, and improve end-user skills and satisfaction with the system. Nurses in all settings can participate in organization-wide committees that discuss and make recommendations for improvements to the system. As EHR users, nurses quickly become the system experts and provide the richest source of ideas for strategies to improve system usability that can help to reduce potential errors and add value to patient care delivery. Optimization is all too often lumped into post-live maintenance and support, but it should be treated separately from routine maintenance (Settergren, 2015). Examples of EHR optimization include:

- Updating a nursing care plan to support an update to a procedure based on new evidence
- Reordering the sequence of screens that initially required nurses to go to three different places in the EHR to document a procedure
- Creating an alert to a nurse when a patient's urinary catheter has been in place for longer than 48 hours
- Adding a patient's code status and allergies to the header of the patient's main screen
- Configuring the system so that data entered by nurses in the pre-admission testing area then flows into the admission section of the chart so the admitting nurse does not need to duplicate the data entry

Table 21-3 Examples of Technology Evaluation Steps

STEPS IN INFORMATICS EVALUATION	DESCRIPTION
1. Determine what will be evaluated.	Determine what to evaluate. Examples: • Adoption and use of the patient portal • Safety of using copy/paste function in the EHR • Effectiveness of modified early warning system on reducing codes called outside of the ICU • Effectiveness of allergy alerting
2. Determine the question.	A clear, focused question helps the team determine what data will need to be collected and how the data ultimately should be reported. Examples: • Has the implementation of the nurse-driven urinary catheter protocol reduced the number of catheter days for patients? • Have the new admission assessment screens resulted in timesaving and improved support of workflow for nurses? • What is the estimated amount of financial savings if automated report printouts were reduced by 50%?
3. Conduct a literature search.	Searches should be conducted in peer-reviewed journals

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	by searching available databases such as Cumulative Index to Nursing and Allied Health Literature (CINAHL), PubMed, and Cochrane Reviews. • Has this topic been studied before? • What data was collected? • What were the findings? • Can we replicate the methods of the study?
4. Determine the needed data.	In this step, the specific data elements to be collected need to be determined. • What data is needed to answer the question? • Is it available? Can the data be easily queried and pulled into a report or spreadsheet for data manipulation? • Who will collect it? • What data collection tool will be used?
5. Determine the study type.	When determining your study design, first take into account the question you are asking, and the data you are collecting to answer the question. • Pre- or postevaluation of an intervention • Retrospective study • Observational study • Time/motion study • Case study • Randomized control trial • Descriptive evaluation of current state
6. Determine the data collection method and sample size.	Clarify exactly how the data will be collected. • Is the data already available in the EHR database (or other database), and you will need the assistance of someone skilled in running a query or developing a report? • Will you need to conduct a manual chart review? • Will you need to observe end users as they interact with the system? • Will you need to conduct a survey? • Will you need a focus group to gather data? • Check sample size and date ranges in previous studies on the same topic • Secure the help of a statistician.
7. Collect, analyze, and display data.	Whether using a table, bar chart, pie chart, or other method, ensure data displays include: • Title with date range and sample size as appropriate • Legends that clearly explain the content and colors • Labels on the x and y axis so the numerical value can be understood • Other descriptors necessary for interpretation
8. Document your outcome evaluation.	Without comprehensive documentation of your evaluation, the chance that any practice improvements occur becomes unlikely. Can use STARE-HI guidelines: http://www.imia-medinfo.org/new2/Stare-HI_as_published.pdf

Source: From Sengstack, P. (2015). Conducting quality healthcare IT outcome evaluations: Guidelines and resources. In P. Sengstack & C. Boicey (Eds.). *Mastering informatics: A healthcare handbook for success*. Sigma Theta Tau International Honor Society of Nursing (Sigma). Adapted and reprinted with permission of Sigma Theta Tau International Honor Society of Nursing (Sigma).

Box 21-2	**Usability Concepts in System Design**

Simplicity: Simplicity in design refers to everything from lack of visual clutter and concise information display to inclusion of only functionality that is needed to effectively accomplish tasks. A "less is more" philosophy is appropriate, with emphasis being given to information needed for decision making.

Naturalness: Naturalness refers to how automatically "familiar" and easy to use (intuitive) the application feels to the user.

Consistency: The more users can apply prior experience to a new system, the lower the learning curve, the more effective their usage, and the fewer their errors.

Minimizing cognitive load: Presenting all the information needed for the task at hand reduces cognitive load. For example, when reviewing results of a lipid profile, the provider will want to see the patient's latest and prior results, the medication list, the problem list, and the allergy list all in the same visual field so that decisions and subsequent actions may be performed without changing screens. Displaying information organized by meaningful relationships is one method of providing cognitive support to the user.

Efficient interactions: One of the most direct ways to facilitate efficient user interactions is to minimize the number of steps it takes to complete tasks and to provide shortcuts for use by frequent and/or experienced users.

Forgiveness and feedback: Forgiveness means that a design allows the user to discover it through exploration without fear of disastrous results. This approach accelerates learning while building in protections against unintended consequences.

Effective use of language: All language used in an EMR should be concise and unambiguous. Terminology used also must be that which is familiar and meaningful to the end users in the context of their work; no terms related to computers, technology, HL7, databases, and so forth should appear in the user interface.

Effective Information Presentation

Appropriate density when designing EMR screens: In clinical applications, there can be so much relevant information to display it can be tempting to pack as much as possible onto a screen. However, visual search times and user errors increase in proportion to density.

Meaningful use of color: Color should be used to convey meaning to the user.

Readability: Screen readability also is a key factor in objectives of efficiency and safety. Clinical users must be able to scan information quickly with high comprehension.

Preservation of context: Screen changes and visual interruptions should be kept to a minimum during completion of a particular task. Visual interruptions include anything that forces users to shift visual focus away from the area on the screen where they are currently reading or working to address something else, and then reestablish focus afterward.

Source: Data from St. John, C. (2015). Designing a usable healthcare information system. In P. Sengstack & C. Boicey (Eds.). *Mastering informatics: A healthcare handbook for success*. Sigma Theta Tau International.

Standard Terminologies

When entering data into an EHR, nurses typically select items from drop-down lists or check boxes that represent an assessment parameter, an intervention, or a patient outcome. Behind the scenes, the data are stored in tables similar to spreadsheets. Each column in the table represents one concept—for example, activity level. The "activity level" column has data in rows that represent each time the data was entered by the nurse for a patient. It can also pull together many patients' activity levels that can be used in a report or analysis.

Whenever possible, data should be entered into the system using **standard terminology** instead of free text. For example, in Table 21-4 on page 560, the column A activity level was allowed to be entered as free text; nurses could type in anything. In column B, nurses were required to pick from a drop-down menu; responses were standardized. Imagine trying to find all the patients over the age of 65, who are on Medicare, whose activity level is "requires assistive device" from column A, where free text data entry was used; it would be impossible. Also, when assessing the acuity of patients to determine case mix and nurse shift assignments, it's important to know patient activity level. Using standard terms allows the development of reports and data that can help to make assignments based on patient care needs.

Without the ability to aggregate and analyze data entered into the EHR, it is a challenge to represent nursing's contribution to patient outcomes and to the organization's bottom line (Whittenburg & Jacobs, 2015). Data entered that represents patient assessment, interventions, and resultant outcomes need to be consistent so the care delivered by nurses can be quantified and nursing's contributions represented. Within this context, the nursing profession, with an estimated 3.4 million members, can contribute an enormous amount of valuable data related to the care of the patient.

Technology Alert

With data stored in a standardized electronic format, the value and contributions of nursing to patient

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

outcomes can be measurable or retrievable (Welton & Harper, 2016). Using standard terminologies is just as important as the ability to use increasingly sophisticated tools to pull data from databases that can unlock an unlimited supply of data just waiting to be tapped into.

Nursing terminologies identify, define, and code care delivery concepts in an organized structure to represent nursing knowledge. The ANA recognizes 12 standard terminologies, which are listed in Table 21-5 on page 560; many of these systems and classifications are described elsewhere in this text (see Chapters 16, 17, and 18).

Table 21-4 Activity Level Descriptions: Free Text versus Standard Terminology

	COLUMN A	COLUMN B
	Free Text	***Standard Terminology (Drop-Down Menu Used)***
Patient A	Stable—doesn't need help with walking	Walks without assistance
Patient B	Walks without problems	Walks without assistance
Patient C	Can't ambulate	Nonambulatory
Patient D	Needs a cane	Requires assistive device
Patient E	Can walk fine	Walks without assistance
Patient F	Okay—but sometimes uses a walker	Requires assistive device

In addition to sharing data among the various entities of a single organization, we are on a journey to share data across the nation, no matter where the data originates or where the patient is seen. Using standard terminology is a foundational step in this journey to ensure patient care can be delivered across the care continuum, and care providers have the right patient data, at the right time, to make safe clinical decisions.

Sharing data and information across nonaffiliated organizations has been an initiative of the Office of the National Coordinator for Health Information Technology, or ONC, part of the U.S. Department of Health and Human Services. In April 2015, Congress declared "a national objective to achieve widespread exchange of health information through interoperable certified EHR technology nationwide by December 31, 2018" (ONC, 2015b). The use of standard terminologies representing nursing care is a first step.

Interoperability

The term used to describe the ability to share patient data across health care systems is **interoperability**. The ONC (2015b) defines interoperability as:

> the ability of a system to exchange electronic health information with and use electronic health information from other systems without special effort on the part of the user. This means that all individuals, their families and health care providers should be able to send, receive, find and use electronic health information in a manner that is appropriate, secure, timely and reliable to support the health and wellness of individuals through informed, shared decision-making. With the right information available at the right time, individuals and caregivers can be active partners and participants in their health and care.

Table 21-5 Nursing Terminologies Recognized by the ANA

ANA-RECOGNIZED TERMINOLOGY/DATA SET	YEAR DEVELOPED	NURSING CONTENT
NANDA-Nursing Diagnoses, Definitions, and Classification	1973	Diagnoses
Omaha System	1975	Diagnoses, interventions, outcome ratings
Nursing Minimum Data Set (NMDS)	1985	Clinical data elements
Nursing Interventions Classification (NIC)	1987	Interventions
Perioperative Nursing Data Set (PNDS)	1988	Diagnoses, interventions,

		outcome
Clinical Care Classification (CCC) System	1988	Diagnoses, interventions, outcome ratings
Nursing Management Minimum Data Set (NMMDS)	1989	Management data elements
International Classification for Nursing Practice (ICNP)	1989	Diagnoses, interventions, outcome
Nursing Outcomes Classification (NOC)	1991	Outcomes
Logical Observation Identifiers Names and Codes (LOINC)	1994	Assessments, outcomes
ABC Codes	1996	Billing codes
SNOMED CT	2000	Diagnoses, interventions, outcomes, findings

Source: From Office of the National Coordinator for Health IT (ONC). (2017). *Standard nursing terminologies: A landscape analysis*. https://www.healthit.gov/sites/default/files/snt_final_05302017.pdf

In 2015, the ONC published *Connecting Health and Care for the Nation: A Shared Nationwide Interoperability Roadmap* (https://www.healthit.gov/sites/default/files/hie-interoperability/nationwide-interoperability-roadmap-final-version-1.0.pdf), which described a long-term goal to "build a strong foundation of health IT in our health care system, equipping every person with a long-term, digital picture of their health over their lifespan" (ONC, 2015b, p. iv). Whether a patient is cared for in a hospital, an ambulatory practice, an outpatient surgery center, or a skilled nursing facility, either in their home state or elsewhere in the country, the patient's data should be easily available to caregivers. Many EHR vendors are now beginning to provide the functionality to pull in patient data from other hospitals where the patient has received care in the past.

This journey toward interoperability will continue, and it will include advances in technologies that support the appropriate sharing of data and the use of standard terminologies. Not surprisingly, to support this effort, federal policies will need to address privacy and security issues surrounding data sharing for patient care and research, and nurses will need to educate themselves and their patients on the importance of understanding how their data is stored and used.

Security and Privacy of Electronic Data

The transition from paper charting to electronic documentation leads to an increased focus on security and privacy. In the paper-and-pen era, the chart was in only one physical location; a limited number of people had access to the chart, and you typically needed to fill out a request form to access it from Medical Records for review. Today, with data residing in electronic systems connected to networks, available from virtually anywhere with an Internet connection, the patient's data now becomes much easier to access by many more people—some without a justified need. Pertinent to this is the Health Insurance Portability and Accountability Act (HIPAA) and the Privacy Rule (see Chapter 20) as well as strategies to ensure the privacy and confidentiality of patient data (see Chapter 7).

Box 21-3 Keeping Data Safe Using Strong Passwords

Never share your password. Don't put it on a sticky note on the front of your computer or any other place that could be identified.

No well-managed site or business asks for your password. Be wary of e-mails, sites, or even callers who request your password—for any reason.

Don't reuse passwords. The password you use for social media should not be the same as the one for your bank account. You can use a common root for the password and make minor changes to reflect the system it's used for.

Use passwords that are easy to remember but hard to guess. You can use a mnemonic device that works for you but is unlikely to work for someone else. For example, create a phrase or sentence such as "I got my RN in 2010 from University of Miami" and then use the initial of each word to create a password, like this: IgmRNin2010fUM. To extend a password's usefulness to multiple sites, make variants by adding or deleting a couple of unique characters for each one. For some sites, you may want to use the entire phrase. You can also use a pass phrase as well, such as: "I like Wisconsin cheese" or "I will graduate in 2020."

Use at least eight characters for your password. Some sources recommend up to 15 characters at a minimum.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Consider using strong authentication or multifactor authentication. To prevent unauthorized users from accessing your account via a device not belonging to you, many companies or websites now offer users the option of verifying their identity. The typical method is to send a code via text or other message format to a mobile device registered to you. You then type in that code to verify that the person seeking access is really you.

Consider using a password manager. There are several programs or web services that let you create a different, very strong password for each of your sites. But you only have to remember that one password to access the program or secure site that stores all of your other passwords. Logons for sites you've selected can even populate the logon automatically when you "land" on those pages.

Source: Adapted from Finn, D., & Dion, W. (2017). *Security tips for using personal technology. Reflections on nursing leadership*. Sigma Theta Tau International Honor Society of Nursing (Sigma). http://www.reflectionsonnursingleadership.org/features/more-features/Vol43_1_security-tips-for-using-personal-technology

Blockchain

Blockchain is digital information (the "block") stored in a public database (the "chain"). Carroll (2020) notes that blockchain can significantly increase data security within health care and the nursing profession due to its superior data accessibility, privacy, auditability, and efficiency. Some of the ways nurses can use blockchain to safeguard patient and personal data as well as purvey knowledge, adding value to the nursing profession include:

- Optimizing patient data management and portability
- Managing professional nurse credentialing and education
- Safeguarding clinical trials and expediting nursing research (pp. 62–63).

QSEN SAFETY

Nurses are responsible to minimize the risk of harm to patients and providers through both system effectiveness and individual performance. Ensuring secure and appropriate access to clinical systems starts with good management of passwords. Guidelines for keeping electronic systems secure with strong passwords can be found in Box 21-3.

EMERGING AREAS IN THE FIELD OF INFORMATICS

As technology becomes increasingly sophisticated, and as care providers, patients, and consumers become more comfortable and proficient with the technologies, we will continue to see advances in health IT and informatics. Reportedly, computers double their capabilities every 12 to 18 months, as do the information technologies and software that use them (Emerging Future, 2012). Health care IT is seeing the emergence of numerous innovations that nurses will need to be familiar with as the pervasiveness of health care technologies grows. The following areas are evolving rapidly, and a basic understanding will help nurses prepare for, adapt to, and participate in the development, implementation, innovation, and evaluation of these tools.

Patient Portals

Engaging patients in their care and working together to improve health with supportive technology is an area that continues to advance. A primary patient engagement tool is the **patient portal**. This web-based tool can be securely accessed and provides functions to increase engagement. Portals are rapidly becoming the platform that links people to telehealth services, remote monitoring, and sometimes are a way to bring patient generated data to the health team. Portals can be accessible via a home computer or a smartphone, making engagement even easier. Depending on the vendor, patient portals can enable the patient to:

- Access medical history and other health information
- Complete various forms and questionnaires online
- Communicate securely and conveniently with providers
- Request prescription refills
- Pay bills
- Review lab results
- Schedule appointments
- Receive reminders for appropriate screenings (e.g., mammograms, flu shots, colonoscopy)
- Enter clinical data, such as blood pressure, glucose levels, weight, Fitbit data, and other activity tracking data
- Review progress notes
- Access educational materials based on diagnosis or procedure

Nurses are beginning to weave the functions of the portal into care delivery workflows in all settings, as patients are now beginning to expect their providers to be able to communicate using the functions and convenience that a portal

provides. Supporting strong patient engagement using a tool such as the patient portal has shown to have multiple benefits (ONC, 2016), including:

- **Better health outcomes.** Encouraging patients to participate in their own health care can result in better preventive care and improve medication adherence.
- **Chronic condition management.** Patient access to information and direct communication with providers can increase the quality of life for patients with chronic disease. Patients can enter their own data on a daily basis for the provider to assess the need for intervention.
- **Timely access to care.** Engagement can result in a level of education that empowers patients to seek the right care at the right time.
- **Patient retention.** Patients who use the portal are nearly 2.6 times more likely to stay patients.
- **Patient-Centered Medical Home recognition.** Patient engagement is a basic element for all levels of Patient-Centered Medical Homes (PCMH) certification.

Encouraging patient engagement using the patient portal is a new competency for nurses that can occur during many different touchpoints in the care delivery process. Whether the patient is in the hospital, visiting a provider in the ambulatory clinic, or in the home health setting, use of the patient portal can be demonstrated and taught. Proxy access for children or for aging adults can also be a great benefit for those caring for loved ones. The convenience of being able to manage a loved one's care plan and communicate with providers via a portal can be an essential tool for healthy outcomes and reduced stress.

Health Care Analytics

Since the implementation of the first EHRs in the 1970s, organizations have been capturing and storing data in an electronic format. You can imagine that the data in those databases has grown exponentially over the years as nurses are continually contributing patient information. The tools to extract the data in order to identify trends and opportunities for improvement are becoming more mainstream and easier to use. Questions can be asked of the data to help drive clinical transformation and assess organizational program effectiveness. Data are now available to address problems in multiple areas. Here are some examples:

- **Clinical:** How many patients with congestive heart failure admitted over the last 3 months have been discharged to home with more than five medications? How many patients currently have had an indwelling urinary catheter in place for longer than 24 hours?
- **Populations:** Can we get a listing of all patients in our organization's Accountable Care Organization (ACO) who are diabetic and have not had a hemoglobin A1c drawn in the last year? (Note: The hemoglobin A1c test tells you the average level of blood sugar over the past 2 to 3 months. It's also called HbA1c, glycated hemoglobin test, and glycohemoglobin. People who have diabetes need this test regularly to see if their levels are staying within range. It can tell if you need to adjust your diabetes medicines.)
- **Administrative:** What nurse staffing ratios are recommended based on patient acuity? What is the hospital's daily census broken down by unit along with occupancy rate?
- **Financial:** Has revenue increased since implementing a new electronic bill pay system?

One way to think about **analytics** is this: If it is entered or stored in a database, then it can be pulled into a report. With increasing sophistication of analytical tools, the ability now exists for data from disparate databases to be pulled into a single report. Organizations are taking data from Medicare claims and melding it with patient satisfaction data and clinical data. The questions that can be asked are virtually limitless with the right tools and expertise. As the tools become increasingly user friendly, nurses will have more opportunities to "self-serve" and "data mine" to find answers to questions that are posing a challenge to care delivery.

Three areas of analytics for which nurses should have a high level of understanding are *data visualization*, *predictive analytics*, and *big data* (Boicey, 2015). Each of these terms is used to describe aspects of analytics work that continues to evolve and is gaining traction in nursing and NI.

Data Visualization

Data visualization is the presentation of data in a pictorial or graphical format (Fig. 21-2). It enables decision makers to see analytics presented visually, so they can grasp difficult concepts or identify new patterns. Because of the way the human brain processes information, using charts or graphs to visualize large amounts of complex data is easier than poring over textual or numerical spreadsheets or reports (Boicey, 2015). Data visualization is a quick, easy way to convey concepts in a universal manner. These graphical formats can be bar charts, pie charts, maps (which can be interactive), bubble graphics, or infographics, and many other formats as well.

Predictive Analytics

Predictive analytics encompasses a variety of statistical techniques that analyze current and historical facts to make predictions about future or otherwise unknown events. In health care, we see this used as organizations attempt to identify patients who are at risk for readmission so case managers can intervene.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

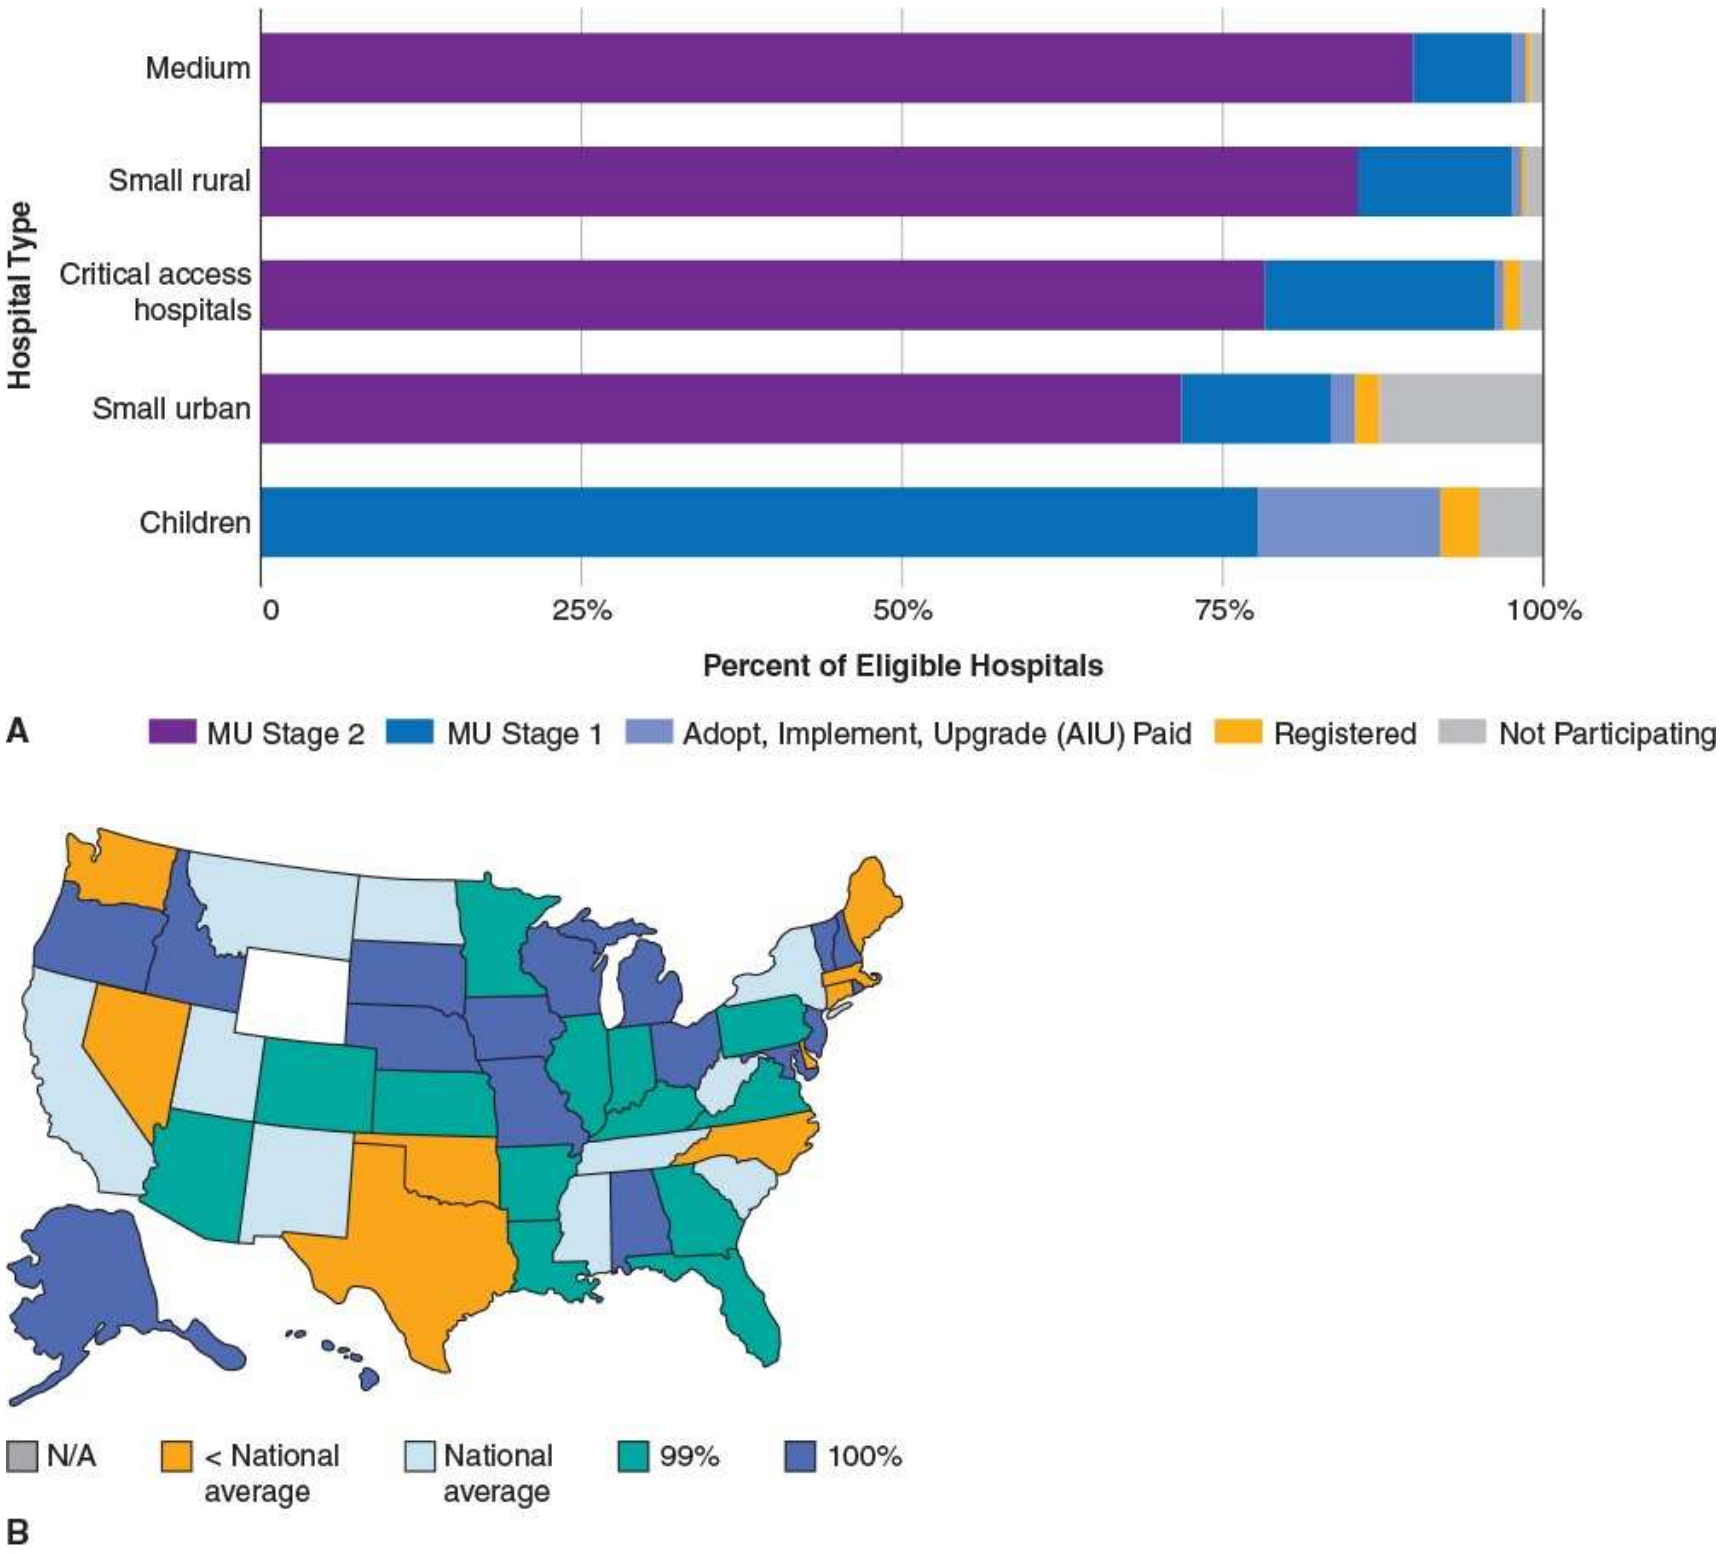

FIGURE 21-2. A. Bar chart showing hospital progress to meaningful use by size, type, and urban/rural location. **B.** Map demonstrating hospitals participating in the CMS EHR incentive programs. Over 95% of all eligible and critical access hospitals have demonstrated meaningful use of certified health IT. (*Source:* From https://dashboard.healthit.gov/quickstats/quickstats.php)

In the case of predicting which patients may develop catheter CAUTIs, recall **Jorge**, who needed a way to identify those patients at risk. Most EHRs now have the ability to display real-time analytic dashboards that indicate which patients on a given unit have had a catheter in place for more than 24 hours, putting them at a higher risk of developing a CAUTI. Many also have the ability to then trigger an alert to the nurse or to the manager to alert them to take action. With a real-time dashboard such as this, Jorge can easily identify any patient that may be at risk and intervene appropriately.

We also see predictive screening for patients who may be at risk for deterioration based on a number of clinical factors so that a preemptive rapid response can be called. Alerts and warnings built into clinical systems based on predictive models continue to evolve as evidence on their effectiveness grows.

Big Data

Big data comprises the accumulation of health care–related data from various sources, combined with new technologies that allow for the transformation of data to information, to knowledge, and ultimately to wisdom. The management of patients who are hospitalized, seen in clinics, or transferred to specialty facilities, as well as those seen in the home, will require us to look at analytics through a new lens. Delivering the required analytics functionality to manage patients, regardless of the setting, necessitates the adoption of big data technologies into our practice. Pulling together data from multiple sources will help health care organizations answer questions and make predictions never before possible as

clinical systems advance, data entered into systems becomes increasingly interoperable, and analytics technology evolves to allow easier use.

Sources of available data can include the following:

- The EHR
- Medical devices such as from physiologic/hemodynamic monitors
- Radiology, laboratory, and pathology systems
- Ventilators
- Wearable devices
- Financial databases
- Genomics information
- Home monitoring systems
- Open sources
- Patient portals
- Real-time location systems
- Smart pumps
- Social media

A team of nurses based at the University of Minnesota has been providing leadership on big data pertinent to nursing practice. In 2016, these nursing leaders brought together expert nurse informaticists to ensure that nursing practice, through use of technology, contributes to a healthier nation. Their vision is described in the 2016 conference proceedings (https://www.nursing.umn.edu/sites/nursing.umn.edu/files/nursing_big_data_proceedings_2016.pdf) and excerpted below:

> We share a vision of better health outcomes resulting from the standardization and integration of the information nurses gather in electronic health records and other information systems, which is increasingly the source of insights and evidence used to prevent, diagnose, treat and evaluate health conditions. The addition of contextual data about patients, including environmental, geographical, behavioral, imaging, and more, will lead to breakthroughs for the health of individuals, families, communities and populations.
>
> This is now an annual conference and includes nurse leaders from around the country.

Example: Using Analytics and Big Data to Support Population Health

Population health addresses the health status and health issues of aggregate populations. It brings significant health concerns into focus and addresses ways in which communities, health care providers, and public health organizations can allocate resources to overcome the problems that drive poor health conditions in the population, such as diabetes, obesity, heart disease, and so forth. Information technology is a part of the core infrastructure on which population health can be assessed and addressed. As organizations transition from the traditional fee-for-service model to value-based payment models (including ACOs), data, information, and knowledge about populations rather than individual patients will be required (HIMSS, 2017). Population health analytics can help organizations identify patients at risk of needing additional assistance to manage their health.

Recall **Frank**, the 72-year-old with COPD from the beginning of the chapter. Population health analytical tools would identify him as being high risk based on data pulled and trended from his record and possibly from other available data sources such as Medicare claims and pharmacy data.

Pulling data together from Medicare and other payor claims and data in the EHR can help predict which patients are at risk for readmission as well as locate patients who are receiving care outside of an organization's network. With this information, care managers can intervene appropriately and target those patients for whom resources will have the greatest impact. An example of the use of analytics to support population health can be seen in Figure 21-3.

Telehealth and Mobile Technologies

Perhaps the most accurate term for this section would be "broadband-enabled health care–related interactions," but the terms *telehealth*, *telemedicine*, and *telecare* are more popular and easier to remember, and all three terms are used. Telehealth seems to be the most commonly used term, as it represents a broad range of interactions, but we sometimes hear all three terms used interchangeably (Fig. 21-4).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

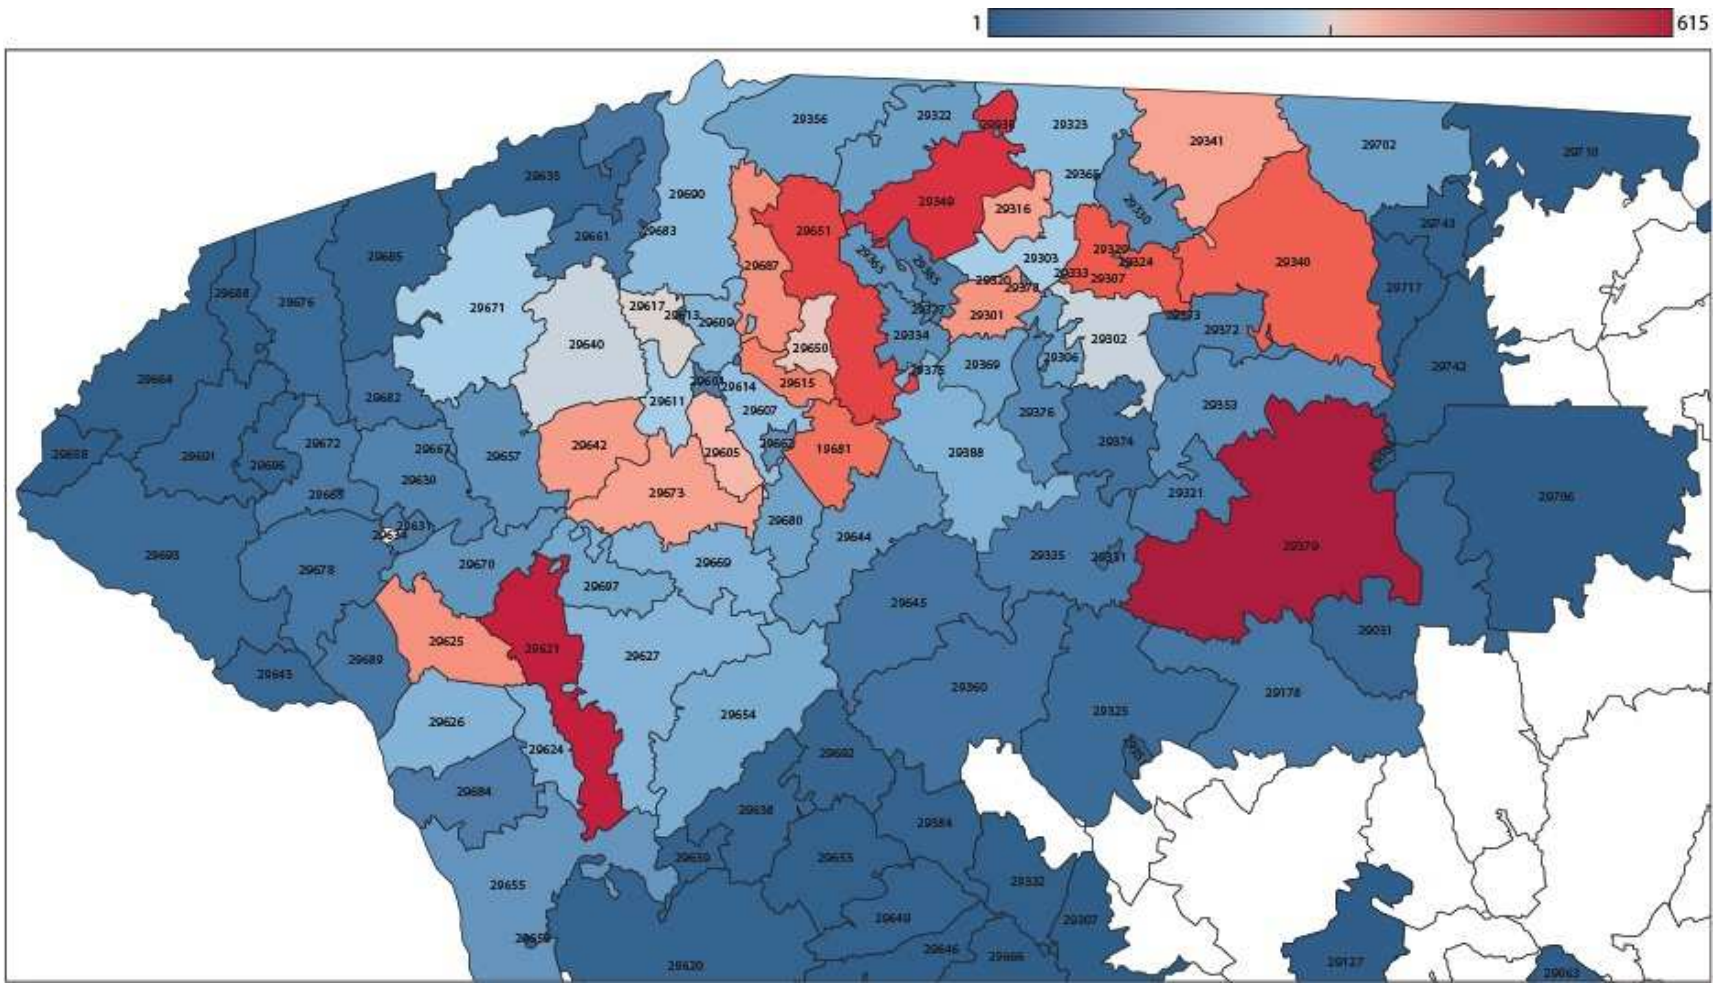

FIGURE 21-3. This example of data visualization illustrates the geographic location (zip codes in South Carolina) for all the patients from an accountable care organization (ACO) who have visited an emergency department (ED) because of the lack of availability of clinics or urgent care centers. The darker red areas indicate the greatest numbers of ED visits and help to provide the information needed by organizations to determine optimal placement of community outreach and establishment of care facilities. (*Source:* Adapted from Bon Secours Health System and Akbar Khan, 2017.)

The Health Resources and Services Administration (HRSA) of the U.S. Department of Health and Human Services defines **telehealth** as "the use of electronic information and telecommunications technologies to support and promote long-distance clinical health care, patient and professional health-related education, public health, and health administration. Technologies include videoconferencing, long distance imaging review, streaming media, and terrestrial and wireless communications" (HRSA & Federal Office of Rural Health Policy, 2015). Telehealth can involve more than just clinical services; it can also include remote nonclinical services such as provider training, administrative meetings, and continuing medical education.

FIGURE 21-4. This nurse is using a telehealth visit to check up on a patient in his home. During the COVID-19 pandemic, he was reluctant to come to the clinic in the hospital. (*Source:* Used with permission form Shutterstock. *Photo by lakshmiprasada S.*)

The Federal Communications Commission defines **telemedicine** as the use of telecommunications technologies to support the delivery of all types of medical, diagnostic, and treatment-related services, usually by physicians or nurse practitioners. Examples include conducting diagnostic tests, monitoring a patient's progress after treatment or therapy, and facilitating access to specialists that are not located in the same place as the patient. Telemedicine involves only remote *clinical* services (FCC, n.d.).

Telecare generally refers to technology that allows consumers to stay safe and independent in their own homes. It may include consumer-oriented health and fitness apps, sensors and tools that connect consumers with family members or other caregivers, exercise tracking tools, digital medication reminder systems, and early warning and detection technologies (FCC, n.d.).

Telehealth does not necessarily promote new health care services, but simply provides a new way to deliver existing

health care services. One of the key advantages of telehealth is allowing patients to remain in their communities while being seen by a health care provider at a remote site. Telehealth saves time and money for patients and reduces the time that patients are away from work. It also plays a more important role as we move away from the traditional fee-for-service system and toward new models of care, including Accountable Care Organizations (ACOs), PCMHs, and other strategies that focus on outcomes. Telehealth technologies are becoming more widely available in the marketplace, much easier to use and implement, and much more affordable (Arellano & Gagnon, 2015).

There are many examples of innovative ways that telehealth is being used to improve care within all health care settings. Simple technologies, such as videoconferencing equipment, provide patients with a live, real-time interaction with a specialist across town or across the country. The provider is able to conduct an evaluation of the patient that includes questioning about history and current symptoms while using electronic diagnostic equipment and peripheral cameras to provide the visual examination. For example, in teledermatology, a high-resolution camera is used for the dermatologist to see a close-up view of the patient's wound or skin condition. Remote monitoring equipment used in home health care allows a nurse to monitor a patient's adherence to medications or vital sign and weight readings. Telepsychiatry is also being explored within skilled nursing facilities located in communities where psychiatrists and other mental health providers are limited. By visually connecting with a provider early to evaluate the patient in the skilled nursing facility, these technologies show a great deal of promise to aid in the reduction of unnecessary hospital readmissions (Arellano & Gagnon, 2015).

Other mobile technologies include the use of "apps" or applications that are available on mobile devices such as smartphones or tablets. The term "mHealth" is used to describe the rapidly evolving use of mobile technologies to track and improve health outcomes. Nurses, physicians, other care providers, and patients are using apps that enable quick and easy access to screens that provide information and can track progress. They often provide a communication platform that allows discussion among key stakeholders including between peers, patients with similar conditions, or care providers. These apps can be interactive and engage users in ways that a typical website cannot. In 2012, 85% of adults in the United States owned a mobile phone, with 53% of these phones categorized as smartphones with the ability to install apps. In addition, nearly 19% of U.S. adults who owned a smartphone had at least one health care–related application on their phone. The majority of these apps focus on tracking diet and/or physical activity (Boudreaux et al., 2014). The number of mobile phone users with a health-related app installed will continue to increase at a rapid pace. With over 40,000 health-related apps available, it is important to evaluate the credibility and reliability of the app prior to use. While there is no one standard methodology or tool to assess the quality of an app, there are some emerging tools and frameworks that can be used including:

. Health On the Net Foundation (HON) (https://www.healthonnet.org)
. Healthcare Information and Management System Society: Selecting a Mobile App: Evaluating the Usability of Medical Applications (http://www.himss.org/selecting-mobile-app-evaluating-usability-medical-applications-0)
. Commonwealth Fund: Developing a Framework for Evaluating the Patient Engagement, Quality, and Safety of Mobile Health Applications (http://www.commonwealthfund.org/~/media/files/publications/issue-brief/2016/feb/1863_singh_framework_evaluating_mobile_health_apps_ib_v2.pdf)

As nursing apps are constantly changing, we recommend that you consult with your faculty about what apps will be most helpful for your clinical experiences and NCLEX preparation. If you use the search phrase "apps for nurses," you will find multiple recommendations for helpful apps.

Hospital at Home

According to Khoury (2021), the hospital-at-home model is just one way health care is evolving to meet patient and cultural demands, better access, equity, and experience. Ideally, treating more patients at home will save inpatient care for the sickest patients. Using telehealth, remote monitoring, and mobile care teams, hospital-at-home programs deliver quality inpatient care in the comfort of one's home. There are numerous benefits to hospital-at-home models which target medium acuity patients whose conditions have well-defined treatment protocols (e.g., COPD and CHF):

- About a third of hospitalized patients over the age of 65 experience delirium, impacting their future health and functioning.
- Older patients also run the risks of hospital-acquired infections, functional decline, falls, and pressure injuries.
- Hospitalization exacts a financial and social tool by keeping patients from work and family responsibilities.

While hospital at home is claimed to benefit patients, providers, and hospitals, there is no question that a major driver is the financial benefit to hospitals and systems who continue to struggle to staff their hospitals, especially the emergency rooms and acute care units. While there is a great opportunity for nurses to provide leadership in what can be an enhanced experience to thousands of patients across the country, nurses must always use their lens of human dignity and well-being to make sure that patients benefit from this shift in delivery models. What experience do you have with patients and families who have experienced hospital at home? Is this available in your area? Would you recommend this experience if asked?

Unique Nurse Identifiers

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Nursing has always struggled to identify and quantify nursing contributions to quality patient outcomes since nurse-sensitive outcomes have been difficult to quantify. "Implementing a unique nurse identifier (UNI) to leverage across systems and technologies will provide evidence of nursing's value to patient care delivery from multiple data sources" (Beale et al., 2021, p. 21). A UNI is a defined code or series of characters that represent an individual nurse within healthcare technology systems and across health care organizations. See the accompanying Table 21-6 to better understand the benefits of UNIs.

Genetics and Genomics: Precision Medicine

The field of genomics has the potential to significantly change the way health care is delivered. Genomics play a role in 9 of the 10 leading causes of death, including heart disease, cancer, stroke, diabetes, and Alzheimer's disease (WHO, 2004). Because genomic health care is heavily dependent on data storage and interpretation, no other area is better suited than informatics to support this evolving work.

Table 21-6 Unique Nurse Identifiers

TERM	DEFINITION	EXAMPLE
Audit trail	Records show who accessed a computer system, when it was accessed, and what actions or operations were performed.	Data are found and displayed in a report about barcode medication administration use derived from the technology and documentation within the electronic health record (EHR).
Interoperability	Different systems, devices, applications, and technologies access, exchange, and use health information for seamless portability.	Interoperability between an IV smart pump and the EHR creates a seamless and closed loop for medication ordering, dispensing, administration, and documentation.
Master data	Consistent and uniform set of identifiers describes core entities (patients, nurses, doctors, hospitals, units) that comprise a health system.	A list of patients in the health system master patient index can be referenced within all technologies and systems.
Meta data	Technology user footprint is created behind the scenes, showing what changes were made in an EHR, who made them and when, as well as what parts of a record were reviewed, for how long, how often, and by whom.	When a user marks a new lab value in a system as "reviewed," the system captures who the user was along with the date and time the reviewed button was selected. Similarly, when an order is marked as signed in the EHR, the user who signed the order is captured, along with the date and time the order was placed.
System integration	Design or construction of an application or technology to incorporate with new or existing hardware or software.	Clinical content from a vendor, such as clinical references or patient education material, are integrated into the EHR.

Source: Used with permission from Beale, N., Carroll, W., Aldrich, K., Alexander, S., Baernholdt, M., & Fields, W. (2021). What a unique nurse identifier means for the future. *American Nurse Journal*, *16*(9), 21–24.

Genomics, or genomic medicine, is defined by the National Human Genome Research Institute (NHGRI) as "an emerging discipline that involves using genomic information about a person as part of their clinical care (e.g., for diagnostic or therapeutic decision making) and the other implications of that clinical use" (NHGRI, 2012). The World Health Organization differentiates the study of genetics and genomics in that genetics scrutinizes the functioning and composition of the single gene whereas genomics addresses all genes and their interrelationships in order to identify their combined influence on the growth and development of the organism.

Genomics can be used to make a diagnosis to assist in treatment decisions or to screen for risks for the development of certain diseases. This screening, or carrier testing, is a type of genetic testing performed on people who display no symptoms for a genetic disorder but may be at risk for passing it on to their children. A carrier for a genetic disorder has inherited one normal and one abnormal allele for a gene associated with the disorder. A child must inherit two abnormal

alleles, one copy from each parent, in order for symptoms to appear (FDA, 2015).

Pharmacogenomics uses information about a person's genetic makeup, or genome, to choose the drugs and drug doses that are likely to work best for that particular person. This new field combines the science of how drugs work, called pharmacology, with the science of the human genome. Until recently, drugs have been developed with the idea that each drug works essentially the same at the prescribed dose for everyone. But genomic research has changed the "one-size-fits-all" approach and has opened the door to more personalized approaches to using and developing drugs. Some drugs may work differently in one person than in another, depending on a person's genetic makeup. Likewise, some drugs may produce more or fewer side effects depending on a person's gene expression. As the body of evidence grows, practitioners will be able to routinely use information about a patient's genetic makeup to choose the most effective and safe drugs (FDA, 2015).

EHR vendors are developing the ability to capture a patient's genetic information in the medical record. Standard terminologies to represent genetic information and gene variants in an electronic system will be imperative to ensure consistency across all care settings and throughout the patient's lifetime. Similar to alerts and reminders for allergies that appear when ordering medications, alerts can be configured in an EHR to notify providers that a genetic test indicates a need to tailor a dosage.

The field of genomics is in its infancy, but we are starting to see examples of its spread to larger populations. For example, the proportion of women with a family health history of breast or ovarian cancer who received genetic counseling increased from 34.6% to 52.9% from 2005 to 2010 (ODPHP, 2017). Also, the Affordable Care Act covers genetic counseling as a preventive service with no out-of-pocket costs for women who have a family health history consistent with increased risk for *BRCA* mutations. And, in 2015, the U.S. Food and Drug Administration (FDA) authorized and approved marketing for a carrier test from genetics testing and analysis company 23andMe. Their Bloom syndrome carrier test is a direct-to-consumer genetic test that can determine whether a healthy person has a variant in a gene that could lead to their offspring inheriting the serious disorder (FDA, 2015). As genomics becomes gradually more mainstream, nurses will see more functionality built into clinical information systems to address personalized care based on a patient's genetic makeup. Exciting times!

Box 21-4 Examples of Pharmacogenomics in Action

- Before prescribing the antiviral drug abacavir for human immunodeficiency virus, doctors now routinely test HIV-infected patients for a genetic variant that makes them more likely to have a bad reaction to the drug.
- The breast cancer drug trastuzumab works only for women whose tumors have a particular genetic profile that leads to overproduction of a protein called HER2.
- The FDA is considering genetic testing for another blood thinner, clopidogrel bisulfate, used to prevent dangerous blood clots. Researchers have found that clopidogrel bisulfate may not work well in people with a certain genetic variant.
- Cancer is a very active area of pharmacogenomic research. Studies have found that the chemotherapy drugs gefitinib and erlotinib work much better in lung cancer patients whose tumors have a certain genetic change. On the other hand, research has shown that the chemotherapy drugs cetuximab and panitumumab do not work very well in the 40% of colon cancer patients whose tumors have a particular genetic change.

Source: From National Human Genome Research Institute (NHGRI). (2016). *Frequently asked questions about pharmacogenomics*. https://www.genome.gov/27530645

Box 21-4 lists some examples of pharmacogenomics in action.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in informatics, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

The cultivation of skill in informatics is a critical component of professional nursing. Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of planning, delivering, and evaluating quality care? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Does your organization use an EHR? If yes, does it use a standard terminology?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Talk with professional nurses about their experiences with both paper and electronic health records and see what they believe are the advantages and disadvantages of both.

. Your unit is encouraging you to discuss the use of patient portals with your patients and families during discharge planning. You understand that portals can deliver personal health information, online appointment scheduling, and personalized, condition-focused alerts and reminders in the form of e-mails, automated telephone calls, or text messages. You have never personally used a patient portal and aren't sure what to discuss in your discharge planning. What do you do?

. You understand that your hospital and unit is far from reaching targeted rates on compliance with handwashing, which is resulting in an unacceptable number of hospital-acquired infections. Someone suggests that your nurse informaticist may be able to help you design and implement a solution. How might you be part of making this happen?

PRACTICING FOR NCLEX

. A nurse informaticist is using the steps of the SDLC to design a new system for home health care documentation. The nurse analyzes the old system and develops plans for the new system. What step of this process will the nurse take next?

a. Testing
b. Designing
c. Implementing
d. Evaluating

. After instituting a new system for recording patient data, a nurse evaluates the "usability" of the system. Which actions will the nurse include in this step? Select all that apply.

a. Checking that the screens are formatted to allow for ease of data entry
b. Reordering the screen sequencing to maximize effective use of the system
c. Ensuring that the computers can be used by specified users effectively
d. Checking that the system is intuitive and supportive of nurses
e. Improving end-user skills and satisfaction with the new system
f. Ensuring patient data is shareable across health care systems

. A nurse is using informatics technology to determine which patients may be at risk for readmission. What term best describes this type of analytic?

a. Data visualization
b. Predictive analytics
c. Big data
d. Data recall

. Nursing students enrolled in an informatics course question the purpose of "big data." Which statement do the students find best describes use of big data?

a. Gathering data from multiple sources to help organizations answer questions and make predictions in multiple settings
b. Predicting patients likely to be readmitted, allowing early intervention
c. Promoting the most efficient staffing model for the organization
d. Developing charts or graphs to visualize large amounts of complex data

. A nurse incorporates use of the patient portal in the discharge teaching for a patient who received a kidney transplant. What services does the nurse explain are available with this technology? Select all that apply.

a. Reviewing diagnostic and lab test results
b. Making follow-up appointments
c. Using health and fitness apps
d. Entering clinical data, such as blood pressure
e. Providing digital medication reminders
f. Requesting prescription refills

. A nurse is testing a new computer program designed to store patient data. During which phase of testing does the nurse determine whether the system can handle high volumes of end users and care providers using the system at the same time?

a. Unit
b. Function
c. Integration
d. Performance

. Nurses test new technology in phases. When will the nurses plan to "test drive" the new system?

a. Unit
b. Function
c. User acceptance
d. Integration

. A nurse is using the steps in informatics evaluation to assess a patient portal. Which activities might occur in the "determining the question" step? Select all that apply.

a. Developing a clear, focused question to determine the data to be collected
b. Determining what to evaluate
c. Determining how the data ultimately should be reported
d. Deciding what specific data elements need to be collected
e. Clarifying exactly how the data will be collected
f. Performing comprehensive documentation of the data collected

. When signing in to the electronic medical record, a nurse is prompted to change their password. Which best-practice guideline does the nurse use to formulate the new password?

a. Password should be at least 8 characters long and unique.
b. Passwords should be memorable and used in other applications.
c. Date of birth makes an ideal password.
d. Nurses should share their passwords with their nurse managers.

. A nurse designing a new EHR system for a pediatric office follows usability concepts in system design. Which concepts are recommended in system design? Select all that apply.

a. Users should not explore with forgiveness for unintended consequences.
b. Shortcuts for frequent users should not be incorporated into the system.
c. Content emphasis should be on information needed for decision making.
d. The less times users need to apply prior experience to a new system the better.
e. All the information needed should be presented to reduce cognitive load.
f. The number of steps it takes to complete tasks should be minimized.

. A nurse wants to be an ethical practitioner. When using informatics, which action best represents ethical practice?

a. Selecting appropriate standardized care plans to meet the patient's needs
b. Gathering data for research studies using the electronic health record of multiple patients
c. Maintaining confidentiality of patient records within legal and regulatory parameters
d. Carrying out all electronic orders entered by the health care provider

. During a feedback session on the updates to the electronic health record, nurses complain that they must use standard terminology rather than enter "free text" data in their own words. How will the nurses developing the system explain the purpose of standardization?

a. It leads to fewer spelling errors and less misrepresentation of data.
b. It provides for easier retrieval of data for use.
c. The program was designed this way, and we cannot change it.
d. Standardization uses preselected terminology, reducing lawsuits.

. A nursing student who is planning their career trajectory tells the nurse preceptor how much they enjoy working with the electronic health record and informatics. What type of graduate program could the preceptor suggest?

a. Clinical nurse specialist
b. Nurse leader
c. Superuser
d. Informatics nurse specialist (INS)

ANSWERS WITH RATIONALES

. **b.** The SDLC focuses on the areas of Analyze and Plan, Design and Build, Test, Train, Implement, Maintain, and Evaluate. After analyzing and planning the new system, the nurse would move on to the design step in which the basic design of the new system is developed. The nurse would then test the system, train employees, and implement, maintain, and evaluate the new system in that order.

. **a, c, d.** Usability refers to the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use. Checking that screens are formatted to allow ease of data entry, ensuring that computers can be used by specified users effectively, and checking that the system is

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

intuitive and supportive of nurses are all tasks related to the "usability" of the system. Maximizing screen sequencing and improving end-user skills and satisfaction with the new system refer to optimization. The ability to share patient data across health care systems is termed interoperability.

- **b.** Predictive analytics uses statistical techniques to analyze current and historical facts to make predictions about future or otherwise unknown events. This is used by health care organizations to identify patients who are at risk for readmission, allowing case managers to intervene. Data visualization presents data in a pictorial or graphical format for analysis. Big data comprises the accumulation of health care–related data from various sources, transforming the data to information, to knowledge, and ultimately to wisdom. Data recall is not a technical term for analytics.
- **a.** As organizations transition from traditional fee-for-service models to value-based payment models, information about populations rather than individuals is needed. Big data comprises the accumulation of health care–related data from multiple sources, combined with new technologies that allow for the transformation of data to information for patient care regardless of setting. Sources of available data can include the EHR; medical devices such as monitors, ventilators, and smart pumps; radiology, laboratory, and pathology systems; wearable devices and home monitoring systems; financial databases; genomics; open sources; patient portals; and real-time location systems. Predictive analytics uses statistical techniques to make predictions about future or unknown events, such as patients who are at risk for readmission. Data visualization presents data in a pictorial or graphical format for analysis. The growing population of older adults with complex health needs and a potential understaffing are important but are not the driving force for the development of this technology.
- **a, b, c, d, f.** The patient portal can streamline services by allowing access to medical history and other health information; facilitating completion of online forms and questionnaires; offering secure and convenient communication with providers; and having the ability to place request prescription refills, pay bills, review lab results, schedule appointments, receive reminders for screenings and immunizations, enter clinical data such as blood pressure, glucose levels, weight, and other activity tracking data, review progress notes, and access educational materials based on diagnosis or procedure.
- **d.** Performance testing is technical and ensures proper functioning of the system and its ability to handle high volumes of care providers using the system at the same time. Unit testing is basic testing that occurs initially. Function testing uses test scripts to validate that a system is working as designed for one particular function. Integration testing uses test script to validate that a system is working as designed for a workflow that integrates multiple components of the system.
- **c.** During the phase "user acceptance," the nurse would "test drive" the new system to ensure it's working as designed. Unit testing is basic testing that occurs initially. Function testing uses test scripts to validate that a system is working as designed for one particular function. Integration testing uses test script to validate that a system is working as designed for an entire workflow that integrates multiple components of the system.
- **a, c.** The nurse develops a clear, focused question to determine the data to be collected and the nurse determines how the data ultimately should be reported during the "determine the question" step. The nurse determines what to evaluate during the step "determine what will be evaluated." The nurse decides what specific data elements need to be collected during the "determine the needed data" step. The nurse clarifies exactly how the data will be collected during the "determine the data collection method and sample size" step. The nurse performs comprehensive documentation of the data collected during the "document your outcome evaluation" step.
- **a.** Passwords should contain 8 to 15 characters, never be shared or re-used, and be easy to remember but hard to guess. Using multifactor authentication and a password manager can help organize and protect information. The password should not be shared with the nurse manager or others.
- **c, e, f.** When designing a system, content emphasis should be on information needed for decision making. All the information needed should be presented to reduce cognitive load. The number of steps it takes to complete tasks should be minimized. The more users can apply prior experience to a new system, the lower the learning curve, the more effective their usage, and the fewer their errors. Forgiveness means that a design allows the user to discover it through exploration without fear of disastrous results or unintended consequences. Minimizing the number of steps needed to complete tasks and to provide shortcuts for use by frequent and/or experienced users facilitates efficient user interactions.
- **c.** The ANA asserts ethical use of informatics principles, standards, and methodologies to establish and maintain health care consumer confidentiality be used within legal and regulatory parameters.
- **b**. Using standard terminology in the electronic health record allows data to be easily retrieved and better captures nursing's contribution to care delivery and patient outcomes. For example, to capture all patients using canes, quad canes, and walkers, a common phrase such as "uses assistive device" allow data for all these mobility issues to be captured.
- **d.** The INS is a registered nurse with formal graduate-level education in informatics. This nurse participates in strategy development, implementation, and maintenance and evaluation of clinical systems, in collaboration with multiple disciplines. The information nurse (IN) is a registered nurse with an interest or experience in informatics, who can assist with the implementation of the EHR or other types of informatics. "Superusers," often trained on the job, assist

others to navigate the EHR. The clinical nurse specialist and nurse leader are patient care focused leadership roles.

UNIT V Actions Basic to Nursing Care

The chapters in Unit IV focus on growth and development through the life cycle. By considering all aspects of the person, nurses provide health care oriented toward wellness and maximize each patient's strengths to reach their potential. (The influences of the family on growth and development are discussed fully in Chapter 4.)

Chapter 22 gives an overview of developmental concepts and theories necessary to understanding growth and development across the lifespan. Major theorists and their contributions to the understanding of psychosocial, physical, cognitive, moral, and spiritual development are described.

Chapter 23 considers the individual from conception through young adulthood. Influences on biological growth and development, as well as physiologic, cognitive, psychosocial, moral, and spiritual development, are discussed. Common health problems of each age group and the role of the nurse in health promotion and illness prevention for each age group are considered.

Chapter 24 discusses the adult years in early, middle, and older-adult stages. The benefits, challenges, and problems associated with normal and abnormal aging are considered. The nurse's role in health care for the adult continues to be important through older adulthood. The chapter ends with a look at the paradigm of aging and stereotypes of older adults. Gerontology and the health care system related to this field are discussed.

Ernestine Wiedenbach (1900–1996), *a faculty member at Yale University School of Nursing, who developed her model of nursing from years of experience in various nursing positions*.

"The concern of nursing is with man in his entirety, his wholeness. Nursing's body of scientific knowledge seeks to describe, explain, and predict about human beings."

Martha Rogers (1914–1994), *a nationally renowned nurse theoretician, author, lecturer, and consultant, whose "theory of man" inspired tremendous creativity, research activity, and intellectual growth in the nursing profession*.

22

Developmental Concepts

Melanie Kimber

Melanie, a 24-year-old single mother, voices concerns about rearing her 12-month-old daughter by herself. “She is just so active, putting toys in her mouth and getting into everything. I’m afraid to look away for even a second because she might get hurt. I don’t know how other parents do it.”

Juan Alvarez

Juan, an 8-year-old boy with encephalitis, becomes violent and combative at times, throwing himself against the bed and muttering words. He immediately calms down when spoken to in Spanish by both an interpreter who visits him and by some of the nurses.

Joseph Logan

Joseph, a 70-year-old man who fell and fractured his hip while repairing the exterior of his home, states, “Go away and leave me alone. I’m a grown man, I can take care of myself … and get rid of this tray. I’m not hungry.” Further investigation reveals that Mr. Logan has been the traditional head of his household and is now troubled by needing others, including his wife, to care for him.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Summarize basic principles of growth and development.
. Identify the impact of genetics, genomics, and epigenetics/epigenomics on growth and development.
. Discuss the theories of Freud, Erikson, Havighurst, Gould, Levinson, Piaget, Kohlberg, Gilligan, and Fowler.
. Describe the importance of incorporating theories of growth and development in assessing and planning nursing care for individuals.
. Explain implications for nursing practice based on an understanding of growth and development.

Humans grow and develop throughout life. **Growth** is an increase in body size or changes in body cell structure, function, and complexity. **Development** is an orderly pattern of changes in structure, thoughts, feelings, or behaviors resulting from maturation, experiences, and learning. Development is a dynamic and continuous process as the individual progresses through life, characterized by a series of ascents, plateaus, and declines. The human processes of growth and development result from the interrelated effects of heredity and environment. Humans simultaneously grow and develop in physical, cognitive, psychosocial, moral, and spiritual dimensions. Each dimension represents an essential part of the whole person.

Nurses promote health in people from birth to death. All people, regardless of age, have unique health care needs that result from their physical, intellectual, emotional, sociocultural, spiritual, and environmental dimensions, which are influenced by their developmental level. To plan and give holistic and individualized care, the nurse must understand typical growth and development characteristics, tasks, and needs of patients of all ages. (See the accompanying Reflective Practice box on pages 576–577.)

This chapter presents theories and principles of growth and development across the lifespan that help us understand both healthy and ill people at various life stages. The major theories examining cognitive, psychosocial, spiritual, and moral development are discussed.

PRINCIPLES OF GROWTH AND DEVELOPMENT

Everyone's physical development has a predetermined genetic base because of inheritance patterns carried on the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

chromosomes. Thus, an unborn child begins life with specific physical attributes. Environmental factors from birth through the early years of growth provide initial psychological and social contact through positive or negative experiences with caregivers. As environmental influences expand beyond the immediate caregivers or family, development is influenced by a wide variety of psychosocial experiences as well as circumstances in the physical environment. Cognitive, moral, and spiritual developments are fostered through interactions within the family (as defined by the individual), school, and community.

The nurse can better understand these interrelated variables at specific life stages through theories of human growth and development. Growth and development are orderly and sequential as well as continuous and complex. All humans experience the same general growth patterns and developmental levels, but, because these patterns and levels are individualized, a wide variation in biological and behavioral changes is normal. Within each developmental level, certain milestones can be identified, such as the first time the infant rolls over, crawls, walks, or says their first words. Although growth and development occur in individual ways for different people, certain generalizations can be made about the nature of human development. These generalizations, outlined in Box 22-1 (on page 577), form the principles that help us understand growth and development.

FACTORS INFLUENCING GROWTH AND DEVELOPMENT

Many factors influence both growth and development. A person's growth and development may be facilitated or delayed by genetics; prenatal, individual, and caregiver factors; and environment and nutrition. Other factors influencing growth and development are health–illness state (discussed in Chapters 3, 4, 23, and 24) and culture (discussed in Chapter 5).

Think back to **Juan**, the 8-year-old boy with encephalitis described at the beginning of the chapter. Although his behavior could be attributed to his infection, we have to consider social determinants of health when considering a child's lived experience.

Because of these often interrelated and interdependent factors, each person's growth and development is individualized. Scientists also continue to debate the idea of nature versus nurture, which considers the relative importance of the combined genes and environment that affect the development of a person.

Genetics, Genomics, and Epigenetics/Epigenomics

At conception, every human receives an equal number of chromosomes from each biological parent. The characteristics inherited from each parent are carried in gene pairs on the 23 pairs of chromosomes, which carry the genetic information that determines the person's cellular differentiation, growth, and function. As a result, physical characteristics such as height, bone size, and eye and hair color are inherited from our family of origin. Other characteristics, such as personality, are not as clearly identified with genetics, but research is ongoing in this area. Genetics also influences the development of many diseases, such as cancer and diabetes. **Heredity** is a term that is sometimes used interchangeably with genetics, but it more directly addresses the transmission of genetics, or what is passed down and inherited from generation to generation.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

Two summers ago, while working in a nurse externship program, I worked with Juan, a Spanish-speaking 8-year-old boy diagnosed with encephalitis inflammation of the brain often secondary to viral or bacterial infection). The boy would become violent and combative at times, throwing himself against the bed and muttering words. Although the brain infection and inflammation could explain Juan's behavior, he became calm when a Spanish interpreter was with him. Juan also would appear calmer when nurses recognized his preferred language and attempted to speak Spanish. Unfortunately, most nurses and physicians would ignore Juan's screams in a language they did not understand, complain about his behavior, and rely on medication to calm him.

On one particular day, I was in the room with a physician who was writing an assessment note for Juan while I was getting Juan's bath water ready for morning care. As usual, Juan was muttering words and thrashing in the bed. I knew some measures to calm him; for example, I would try to use the few Spanish

words I knew. The physician remained in her chair, looking at me and complaining about Juan's behavior, not making any effort to calm him. She said that she could not do anything to calm him down except prescribe sedative medications. I felt bad for the patient and knew he was frustrated. I knew that I could possibly help in this situation but did not want to show disrespect to the physician.

Thinking Outside the Box: Possible Courses of Action

- I could nod in agreement with the physician. After all, I was only a nursing student and appreciated that she certainly knew more than I did.
- I could tell her what measures I had used to help calm Juan.
- I could refrain from saying anything at all, wait until the physician had left, and then try to calm Juan.

Evaluating a Good Outcome: How Do I Define Success?

- The patient benefited from my actions.
- I did not disrespect the physician, and worked to develop a collaborative relationship with her.
- I was able to use my intuition, authority, and common sense to the best of my ability.
- Did I have the authority to jump in and give the physician advice on how to care for the patient?
- In this situation, my intuition and common sense told me to jump up and take action to provide compassionate care to Juan, who was frustrated and upset.

Personal Learning: Here's to the Future!

Unfortunately, in this situation, I did not respond as I would have liked to. I did not say anything, but watched Juan become upset and mutter Spanish words. During this whole time, the physician shook her head, looked down on him, and told me she just "couldn't do anything about him" except to give him medications. I waited until the physician left, and then tried to calm Juan myself. In this situation, I should have let the physician know about the methods used to calm Juan previously, which may have minimized the perceived or actual need for sedatives. However, as a junior level nursing student, I did not feel comfortable enough to use this type of authority. I now see how important it is for nurses and all staff members to communicate their opinions, beliefs, and observations about patients for the benefit of the patient. These suggestions and opinions need to be heard so that patients receive the best possible care. In the future, as a practicing nurse, I will respect my fellow staff members, but always make sure that my voice is heard concerning a patient's needs.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? Can you think of other ways to respond or approach the situation? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety when caring for patients like Juan?

Patient-Centered Care: Why was a third-party medical interpreter/translator not considered for Juan? What do you think Juan might have been experiencing and why? What if the nursing student had approached the physician about using other methods to calm Juan? Would you consider that action to be disrespectful? How do you think the physician would have responded to the nursing student's feedback about the use of the Spanish language to calm Juan? Would simply modeling the interventions and behavior that previously had worked with Juan provide cues for the physician?

Teamwork and Collaboration/Quality Improvement: Did the physician's age or gender impact on your decision making? What communication skills do you need to improve to ensure that you function as a member of the patient care team and minimize risk of harm to Juan? Would collaboration with your instructor or Juan's nurse have resulted in additional alternatives or another approach to communicate calmly and safely with Juan?

Safety/Evidence-Based Practice: Would Juan's stage of growth and development influence your nursing care? Do you think that the nursing student's stage of growth and development may have played a role in the student's response? Why or why not? Would an effort to identify common Spanish words and phrases and have them available to all caregivers make a difference? Are we missing cultural or other factors due to the language barrier? What evidence in nursing literature provides guidance for decision making about methods to ensure a safe environment for a young child who does not understand English? How do we

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

begin to assess and address social determinants of health related to Juan and his family and caregivers?

Informatics: Can you identify the essential information that needs to be included and documented in Juan's electronic record regarding efforts to communicate with him and give nursing care? Is it important to document your assessments and interventions? Can you identify any additional information that supports safe patient care and coordination of care? What technology can be used to ensure Juan has the medical interpreter/translator he may need? How can we ensure holistic care for Juan that takes into consideration individual and environmental factors?

The Human Genome Project (HGP), completed in 2003, was an international 13-year collaborative research program whose goal was to map the genes in human DNA, determined to number approximately 20,500 by the HGP (National Human Genome Research Institute, 2020b). A **genome** is the complete set of DNA in an organism, including all its genes. You can appreciate the challenging complexity of the HGP when you consider that human DNA, developed from four different chemical building blocks called *bases*, involves approximately 3 billion bases arranged along the chromosomes in a particular order that is unique for each person (U.S. National Library of Medicine, 2021). The HGP deciphered the human genome by: (1) determining the order or sequence of all the bases in human DNA, (2) making maps that show the locations of genes on chromosomes, and (3) making linkage maps that track inherited traits over generations (National Human Genome Research Institute, 2020b). Another initiative, the 1000 Genomes Project (International Genome Sample Resource [IGSR], 2021), which ran between 2008 and 2015, provided the largest public catalog of human genome data available to date, while focusing on identifying genetic variances with frequencies of 1% or greater in the populations studied. These projects have led to the discovery of genetic sequencing and variants that provide valuable information regarding genomics.

Box 22-1 Principles of Growth and Development

Growth and development are orderly and sequential, as well as continuous and complex. All humans experience predictable growth patterns and developmental levels. Because these patterns and levels are complex and individualized, a wide variation in biological and behavioral changes is considered normal. Within each developmental level, certain milestones can be identified. For example, the timing of when the infant rolls over, crawls, walks, or talks is fairly predictable.

Growth and development follow regular and predictable trends. Cephalocaudal (proceeding from head to tail) development is the first trend, with the head and brain developing first, followed by the trunk, legs, and feet. The second trend is proximodistal development, which means that growth progresses from gross motor movements (such as learning to lift the head) to fine motor movements (such as learning to pick up a toy with the fingers). The last trend is symmetric development of the body, with both sides of the body developing equally.

Growth and development are both differentiated and integrated. As nerve pathways develop, they become more specialized, allowing the growing child to respond to different stimuli. Throughout the lifespan, each new learned ability builds on previously learned abilities so that increasingly complex tasks can be accomplished. For example, the toddler learning to use a spoon combines motor skills, hand–eye coordination, cognitive patterning, and social imitation from watching others. As children grow and develop, the task of learning to use a spoon becomes basic, forming the foundation for learning skills requiring more manual dexterity.

Different aspects of growth and development occur at different stages and at different rates and can be modified. For example, muscles and bones both grow most rapidly during the first year of life. During the toddler and preschool years, bone growth slows, but muscle fibers increase in size and strength. The most intense period of speech development is between 3 and 5 years of age. Sexual maturity begins during the preadolescent years and progresses into the adult years but is based on gender and sex role identity established from birth. Many factors can modify growth and development, including social determinants of health, love and affection from caregivers, and illnesses.

The pace of growth and development is specific for each person. Both physical and psychological skills and maturation vary among people. For example, while learning to walk, a child may concentrate energies on that task and temporarily lag in language development. In addition, a person's genetics places restrictions on the upper limits that can be achieved in growth.

QSEN INTERNATIONAL GENOME SAMPLE RESOURCE

The 1000 Genomes Project led to the creation of the IGSR to ensure access to the 1000 Genomes

reference data, to track and incorporate additional published data on the existing populations, and to expand the project to populations not included in the original 1000 Genomes Project. This online database gives scientists access to data on genomes for research projects and is an excellent example of a high-quality electronic source that provides insight into the human genome.

Genomics is the study of the structure and interactions of all the genes in the human body, including their interactions with each other and the environment. Health care providers all over the world integrate genomics into their research, education, and practice (Office of Disease Prevention and Health Promotion, 2021). Genetic tests, coupled with family history tools, have the potential to identify people at risk for diseases. There are several emerging challenges related to genomic discoveries:

- Evidence-based review panels are needed to thoroughly evaluate the possible benefits and harms related to the expanding number of genetic tests and family health history tools.
- Valid and reliable national data are needed to establish baseline measures and track progress for populations while identifying disparities in their use and outcomes.
- Translating research recommendations into practice and policy requires specific knowledge of the topic and consideration of efficacy, equity, and transparency.
- Privacy and confidentiality must be considered when integrating genomic information into electronic health records (EHRs), clinical decision models, and education curricula (Office of Disease Prevention and Health Promotion, 2021).

Epigenetics is an emerging field of study that is still undergoing definition and refinement. First appearing in the 1940s, **epigenetics** is generally defined as the study of the changes that occur in organisms due to modification of gene expression and hereditability, not a change in the DNA sequence (Deans & Maggert, 2015; National Cancer Institute, 2020). One of the primary challenges when considering epigenetics is determining whether changes in gene expression are due to the inheritance of an expression state or another stimulus (Deans & Maggert, 2015). For example, **epigenomics**—epigenetic changes that occur in many genes or the entire organism—considers whether smoking, which affects how genomes are expressed in the person who smokes, also affects offspring of the person who smokes (National Cancer Institute, 2020; National Human Genome Research Institute, 2020a). Social epigenomics considers social determinants of health, specifically adverse social and environmental experiences in childhood and their relationship to the development of dysfunctional physiologic changes later in life (National Cancer Institute, 2020). See Chapter 3 for more on the social determinants of health.

Nurses must be prepared to answer questions and discuss the impact of genetic findings on health and illness. Advances in genetics and genomics affect everyday nursing practice in areas such as screening, diagnoses, treatment plans, and pharmacogenomics, as well as lifestyle choices and associated ethical challenges (American Nurses Association [ANA], n.d.). Resources for genetic technology and information are included in Box 22-2.

Box 22-2 Genetic Technology and Information Resources

American Academy of Pediatrics (AAP)

Council on Genetics (COG), https://www.aap.org/en/community/aap-councils/genetics/. Provides information about genetic testing and counseling for providers and patients.

American Nurses Association (ANA)

Ethics topics and articles, genetics, and personalized medicine, https://www.nursingworld.org/practice-policy/nursing-excellence/ethics/genetics/. Provides current publications and resources focused on genetics and genomics, with a focus on education and ethical issues.

International Society of Nurses in Genetics (ISONG)

https://www.isong.org/. Focused on supporting the professional growth of nurses with respect to human genetics and genomics in practice, education, and research; global perspective; precision medicine.

United States Surgeon General

My Family Health Portrait: https://www.cdc.gov/genomics/famhistory/knowing_not_enough.htm, from the Surgeon General. Aids in construction of a family health history, including risks for conditions that run in the family.

National Human Genome Research Institute (NHGRI)

www.genome.gov. Provides continued access to data obtained from the HGP, information about genetic services, and access to relevant research.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

National Institutes of Health (NIH)

Genetic Testing Registry (GTR): http://www.ncbi.nlm.nih.gov/gtr. Serves as a repository for patient-submitted data on genetic conditions, genes, and labs; provides resources.

National Society of Genetic Counselors (NSGC)

Find a Genetic Counselor: http://www.nsgc.org/page/find-a-gc-search. Locates genetic nurse counseling services according to zip code location, and provides patient information, policies, and publications.

Prenatal, Individual, and Caregiver Factors

Fetal development can be affected by maternal age (with greater risk in pregnant persons younger than 15 years of age and those older than 35 years of age), inadequate prenatal care, inadequate maternal nutrition, and maternal substance use disorder. Individual factors that can affect development from birth through adolescence include congenital or genetic disorders, brain damage from accidents or abuse, vision and hearing impairments, chronic illness, inadequate nutrition, chemotherapy or radiation therapy, lead poisoning, poverty, and substance abuse. Caregiver factors that negatively affect development include neglect and abuse, mental illness, intellectual disabilities, and severe learning disabilities.

Environment and Nutrition

Environment and nutrition influence all stages of development. Environmental factors that may alter development include social determinants of health such as poverty, violence, unsafe living conditions, the presence of lead or mold in the home, and the quality of air and water in the surrounding environment. Environmental and nutritional effects can occur independently, but they are more likely to be interrelated, as seen in these examples:

- Infants who are malnourished in utero develop fewer brain cells than infants who have had adequate prenatal nutrition.
- Substance use disorder by a pregnant person increases the risk for congenital anomalies, low birth weight, and prematurity in the developing fetus.
- Failure to thrive, a condition of early infancy, has been linked to both nutritional and emotional deprivation.
- Environmental challenges, such as substandard housing and inadequate medical care, can compound the effects of poor nutrition.
- Child abuse, which is an extreme example of physical and emotional harm or deprivation, leads to deficits in physical or psychosocial development, or both.
- Substance use disorder by adolescents and young adults is associated with an increased incidence of teenage pregnancy, violence, accidents, and suicide. Abuse of alcohol and drugs is more prevalent in teenagers who have poor family relationships, low self-esteem, and poor social skills.
- Nutritional influences such as overeating and inactivity as well as genetic factors are directly related to obesity.

OVERVIEW OF CLASSIC DEVELOPMENTAL THEORIES

Human development and behavior have been studied since the beginning of the 20th century. Many theories seek to explain typical human responses at specific ages and stages of life. Although a psychological approach is common to most developmental theories, each theory has a different focus. The theories discussed in the following sections examine cognitive, social, and instinctual influences on human growth and development, with key points summarized in Table 22-1 (on page 580).

Theory of Psychoanalytic Development

Sigmund Freud

Freud's theory emphasizes the effect of instinctual human drives on behavior. Freud identified the underlying stimulus for human behavior as sexuality, which he called *libido*. Libido is defined as general pleasure-seeking instincts rather than purely genital gratification.

The four major components of the mind according to Freud's theory are the unconscious mind, the id, the ego, and the superego:

- The *unconscious mind* contains memories, motives, fantasies, and fears that are not easily recalled but that directly affect behavior.
- The *id* is the part of the mind concerned with self-gratification by the easiest and quickest available means. *Defense mechanisms* are a means of unconscious coping to reduce stress in the conscious mind when the id's impulses cannot be satisfied. (Defense mechanisms are discussed in Chapter 43.)
- The *ego* is the conscious part of the mind that serves as a mediator between the desires of the id and the constraints of reality so that a person can live effectively within their social, physical, and psychological environment. The ego includes intelligence, memory, problem solving, separation of reality from fantasy, and incorporation of experiences and learning into future behavior. Freud noted that the death of a loved one can result in the loss of a person's sense of identity, but once the loss is accepted, the ego is able to reconcile the loss and search for new attachments.

Development of the ego allows the infant, by age 6 months, to view self as separate from others and to begin to alter behaviors in response to cues. Ego development continues throughout life.

- The *superego* is the part of the mind commonly called the conscience. It develops from the ego during the first year of life, as the child learns praise versus punishment for actions. The superego represents the internalization of rules and values so that socially acceptable behavior is practiced.

Each of the following developmental stages typically involves certain issues; any unresolved issues can persist into adulthood. Freud's work describes sexuality (including sex, gender, and sexual orientation) through a heteronormative lens.

ORAL STAGE (AGES BIRTH TO 18 MONTHS)

During the oral stage, the infant uses the mouth as the major source of gratification and exploration. Pleasure is experienced from eating, biting, chewing, and sucking. The infant's primary need is for security. A major conflict occurs with weaning.

Recall **Ms. Kimber**, the young, single, frustrated mother of a 12-month-old child. The nurse might apply the concepts of Freud's theory in the nursing care of Ms. Kimber and her child by explaining the oral behaviors typical of the stage of her child's development.

Table 22-1 **Key Points of Developmental Theories: Instinctual, Cognitive, and Social**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	FREUD PSYCHOSEXUAL	PIAGET COGNITIVE	ERIKSON PSYCHOSOCIAL[a]	HAVIGHURST DEVELOPMENTAL
Infancy to toddlerhood	*Oral stage:* Focus on sucking, biting, chewing, and swallowing *Anal stage:* Focus on bowel and bladder control; anus becomes the center of gratification	*Sensorimotor stage:* Basic reflexes; coordinates more than one thought at a time; begins to reason and anticipate events	*Trust versus mistrust (infant):* Uncertainty; development of hope *Autonomy versus shame and doubt (toddler):* Exploration of the limits of abilities; development of will	Learning to walk; learning to talk; learning to control body waste elimination
Preschool to early school years	*Phallic stage:* Resolving Oedipal/ Electra complex	*Preoperational stage:* Increased language; increased understanding of life events and relationships	*Initiative versus guilt:* Development of interpersonal skills through activities with others; development of purpose	Learning sex differences; forming concepts; getting ready to read
School years	*Latent stage:* No meaningful focus	*Concrete operational stage:* Develops logical thinking; incorporates others' perspectives; uses abstract thinking and deductive reasoning; tests beliefs to establish values *Formal operational stage:* Adopts life-guiding values or religious practices	*Industry versus inferiority:* Self-esteem based on feedback from others; development of competence	Learning physical skills; learning to get along with others; developing conscience and morality; developing fundamental skills in reading, writing, and math; developing concepts related to everyday living; achieving personal independence; developing attitudes toward social groups, institutions, and toward oneself
Adolescent to adult years	*Genital stage:* Reaching full sexual maturity		*Identity versus role confusion (adolescence):* Exploration for personal identity and a sense of self; development of fidelity *Intimacy versus isolation (young adulthood):* Development of happy relationships and a sense of commitment, safety, and caring; development of love	Achieving a gender role; achieving emotional independence; acquiring a set of values and an ethical system to guide socially responsible behavior; preparing for marriage, a family life, and a career
Middle adult years			*Generativity versus stagnation:* Establishment of career, relationships, family, and societal engagement; development of care	Achieving social and civic responsibility; accepting and adjusting to physical changes
Later adult years			*Ego integrity versus despair:* Change in productivity goals and evaluation of success; development of wisdom	Adjusting to decreasing physical status and health; adjusting to retirement

FIGURE 22-1. Sharing baking experiences allows this preschool girl to imitate activities that she often sees her mother enjoy.

ANAL STAGE (AGES 8 MONTHS TO 3 YEARS)

This stage begins with the development of neuromuscular control to allow control of the anal sphincter. Toilet training is a crucial issue that requires delayed gratification as the child compromises between enjoyment of bowel function and limits set by social expectations.

PHALLIC STAGE (AGES 3 TO 7 YEARS)

The child has increased interest in sex differences and in their own sex (Fig. 22-1). The child experiences conflict and resolution of that conflict with the parent of the same sex (named the *Oedipus complex* in boys and the *Electra complex* in girls, based on feelings of intimate sexual possessiveness for the opposite-sex parent). Curiosity about the genitals and masturbation increases during this stage.

LATENCY STAGE (AGES 7 TO 12 YEARS)

This stage marks the transition to the genital stage during adolescence. Increasing sex-role identification with the parent of the same sex prepares the child for adult roles and relationships.

GENITAL STAGE (AGES 12 TO 20 YEARS)

At this stage, sexual interest can be expressed in overt sexual relationships. Sexual pressures and conflicts typically cause turmoil as the adolescent makes adjustments in relationships.

Theory of Cognitive Development

Jean Piaget

Piaget and Inhelder (1969) developed a theory of **cognitive development** from infancy through adolescence. Piaget believed that learning occurs as a result of the internal organization of an event in which a mental schema (plan) is formed and serves as a base for further schemata as one grows and develops. Intellectual growth is a continual restructuring of knowledge to progress to higher levels of problem solving and critical thinking. Two continual processes of restructuring knowledge—assimilation and accommodation—stimulate intellectual growth in the child. **Assimilation** is the process of integrating new experiences into existing schemata. **Accommodation** is an alteration of existing thought processes to manage more complex information.

Piaget and Inhelder described four stages of cognitive development (although Piaget sometimes referred to three periods and combined the preoperational and concrete operational stages).

SENSORIMOTOR STAGE (BIRTH TO AGE 2 OR 3 YEARS)

This stage is marked by progression through a series of six substages with specific developmental tasks:

- Birth to 1 month: Demonstrates basic reflexes, such as sucking
- 1 to 4 months: Discovers enjoyment of random behaviors (such as smiling or sucking thumb) and repeats them
- 4 to 8 months: Relates own behavior to a change in environment, such as shaking a rattle to hear the sound or manipulating a spoon to eat
- 8 to 12 months: Coordinates more than one thought pattern at a time to reach a goal, such as repeatedly throwing an object on the floor; only objects in sight are considered permanent
- 12 to 18 months: Recognizes the permanence of objects, even if out of sight; can understand simple commands
- 18 to 24 months: Begins to develop reasoning and can anticipate events

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Ms. Kimber**, the single mother of a 12-month-old infant. Applying Piaget's theory, the nurse could develop a teaching plan for the mother that addresses appropriate anticipatory guidance to prevent injury while fostering the child's cognitive development.

PREOPERATIONAL STAGE (AGES 2 OR 3 TO 6 OR 7 YEARS)

This stage is characterized by the beginning use of symbols, through increased language skills and pictures, to represent the preschooler's world (Fig. 22-2 on page 582). This stage is divided into two parts: the preconceptual stage (ages 2 to 4 years) and the intuitive stage (ages 4 to 7 years). Play activities during this time help the child understand life events and relationships.

CONCRETE OPERATIONAL STAGE (AGES 6 OR 7 TO 11 OR 12 YEARS)

During this stage, children learn by manipulating concrete or tangible objects and can classify articles according to two or more characteristics. Logical thinking is developing, with an understanding of reversibility, relations between numbers, and loss of egocentricity that develops into the ability to incorporate another's perspective. Children become increasingly aware of external events and realize that their feelings and thoughts are unique and may not be the same as those of other children of their age. They have the ability to focus on multiple parts of a problem at the same time.

FIGURE 22-2. This child's cognitive development is characterized by the ability to learn simple sequences and relationships. (*Source: Photo by Yulia_B./Shutterstock*.)

FORMAL OPERATIONAL STAGE (AGES 11 OR 12 TO 14 OR 15 YEARS)

This stage is characterized by the use of abstract thinking and deductive reasoning. General concepts are related to specific situations and alternatives are considered. The world is evaluated by testing beliefs in an attempt to establish values and meaning in life.

Theories of Psychosocial Development

Erik Erikson

Erikson's (1963) developmental theory expanded on Freud's work to include cultural and social influences in addition to biological processes. His psychosocial theory is based on four major organizing concepts:

- Stages of development
- Developmental goals or tasks
- Psychosocial crises
- Process of coping

Erikson believed that development is a continuous process with distinct stages, characterized by the achievement of developmental goals that are affected by the social environment and significant others. He identified eight stages that progress from birth to old age and death. Each stage is characterized by a developmental crisis to be mastered, with possible successful or unsuccessful resolution of the crisis. Unsuccessful resolution at any one stage may delay progress through the next stage, but mastery can occur later.

FIGURE 22-3. This caregiver provides comfort and affection to his daughter, teaching her to trust in others. (*Source:* Used with permission from Shutterstock. *Photo by Joe Mitchell.*)

TRUST VERSUS MISTRUST (INFANT)

The infant learns to rely on caregivers to meet basic needs of warmth, food, comfort, and forming trust in others. Mistrust can result from inconsistent, inadequate, or unsafe care (Fig. 22-3).

AUTONOMY VERSUS SHAME AND DOUBT (TODDLER)

As motor and language skills develop, the toddler (ages 1 to 3 years) learns from the environment and gains independence through encouragement from caregivers to feed, dress, and toilet themselves. If the caregivers are overprotective or have expectations that are too high, shame, doubt, and feelings of inadequacy may develop in the child.

Think back to **Ms. Kimber**, the mother raising her child on her own. The nurse could apply Erikson's theory to explain her daughter's "getting into everything" as her need for learning about the environment and gaining independence. Additionally, the mother's anxiety level and the child's attempts to investigate the environment through locomotion and oral exploration, place the child at risk for injury from a fall or aspiration of a small object. With astute observation and knowledge of child development, the nurse plays a primary role in prevention by educating the mother.

FIGURE 22-4. School-aged children focus on the end results of accomplishments—recognition and praise from family, teachers, and peers—in their development of a sense of competition and industry.

INITIATIVE VERSUS GUILT (PRESCHOOL)

Confidence gained as a toddler allows the preschooler (ages 4 to 6 years) to take the initiative in learning so that the child actively seeks out new experiences and explores the how and why of activities. If the child experiences restrictions or reprimands for seeking new experiences and learning, guilt results, and the child hesitates to attempt more challenging skills in motor or language development.

INDUSTRY VERSUS INFERIORITY (SCHOOL-AGED CHILDREN)

Focusing on the end result of achievements, the school-aged child gains pleasure from finishing projects and receiving recognition for accomplishments (Fig. 22-4). If the child is not accepted by peers or cannot meet parental expectations, a feeling of inferiority and lack of self-worth may develop.

Think back to **Juan**, the 8-year-old boy described at the beginning of the chapter. The nurse could help to foster Juan's industry by offering positive reinforcement when he responds appropriately to efforts to calm him. The nurse also could incorporate activities that interest Juan into his plan of care to provide him with opportunities to succeed.

IDENTITY VERSUS ROLE CONFUSION (ADOLESCENCE)

With many physical changes occurring, the adolescent is in transition from childhood to adulthood. Hormonal changes produce secondary sex characteristics and mood swings. Trying on roles and even rebellion can be normal behaviors as the adolescent acquires a sense of self and decides what direction to take in life. Role confusion occurs if the adolescent is unable to establish identity and a sense of direction.

INTIMACY VERSUS ISOLATION (YOUNG ADULTHOOD)

The tasks for the young adult are to establish close, honest, loving relationships and make commitments to others. Fear of such commitments results in isolation and loneliness.

Recall **Ms. Kimber**, the mother described at the beginning of the chapter. She has identified a limited support system. Recognizing this, the nurse can assess further to identify the mother's potential problems with intimacy and subsequently, her progression toward generativity.

GENERATIVITY VERSUS STAGNATION (MIDDLE ADULTHOOD)

The middle adult years are marked by involvement with family, friends, and community. There is also a tendency to become concerned for the next generation and desire to make a contribution to the world. If this task is not met,

stagnation occurs, and the person becomes self-absorbed and obsessed with their own needs, or regresses to an earlier level of coping.

EGO INTEGRITY VERSUS DESPAIR (LATER ADULTHOOD)

As a person enters the older years, reminiscence about life events provides a sense of fulfillment and purpose. Some older adults may not be fearful of dying if they feel they have achieved integrity. If a person believes their life has been a series of failures or missed opportunities, a sense of despair may prevail.

Think back to **Mr. Logan**, the 70-year-old man who broke his hip. Applying Erikson's theory, the nurse could assess Mr. Logan for indications of despair due to his feelings of dependency on others, and plan appropriate interventions that foster a sense of fulfillment and purpose.

Robert J. Havighurst

Havighurst (1972) believed that living and growing are based on learning, and that a person must continuously learn to adjust to changing conditions. He described learned behaviors as **developmental tasks** that occur at certain periods in life. Successful achievement leads to happiness and success in later tasks, whereas unsuccessful achievement leads to unhappiness, societal disapproval, and difficulty in later tasks. The developmental tasks arise from maturation, personal motives, and values that determine occupational and family choices and civic responsibility.

INFANCY AND EARLY CHILDHOOD

Developmental tasks for infancy and early childhood include:

- Achieving physiologic stability
- Learning to eat solid foods
- Learning to walk and talk
- Forming simple concepts of social and physical reality
- Learning to relate emotionally to parents or caregivers, siblings, and other people
- Learning to control the elimination of body wastes
- Learning to distinguish between right and wrong
- Learning sex differences and sexual modesty

MIDDLE CHILDHOOD

Developmental tasks for middle childhood include:

- Learning physical skills necessary for games
- Learning to get along with peers
- Developing fundamental skills in reading, writing, and mathematics
- Developing a conscience, morality, and a set of values
- Achieving personal independence

ADOLESCENCE

Developmental tasks for adolescence include:

- Accepting their body and using it effectively
- Achieving a masculine or feminine gender role (this binary reflects the time of Havighurst)
- Achieving emotional independence from parents and other adults
- Preparing for a career
- Preparing for marriage and family life
- Desiring and achieving socially responsible behavior
- Acquiring an ethical system as a guide to behavior

YOUNG ADULTHOOD

Developmental tasks for young adulthood include:

- Selecting a mate (Fig. 22-5)
- Learning to live with a (marriage) partner
- Starting a family and rearing children
- Managing a home
- Getting started in an occupation (see the accompanying Research in Nursing box)
- Taking on civic responsibility

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Finding a congenial social group

FIGURE 22-5. Choosing a life partner is often an important developmental task for young adults.

Research in Nursing

BRIDGING THE GAP TO EVIDENCE-BASED PRACTICE

The Impact of Job Loss on Maternal Sensitivity

Maternal sensitivity, the ability of a mother to be attuned and responsive to their child in nondistressed contexts, affects developmental outcomes in the child. The relationship between mother and child, especially the first 3 years of life, impacts social, cognitive, and emotional development. Job instability and unexpected job loss affect more than income; changing roles, emotional reactions, work–family conflict, change in caregiving dynamics, and education-related job mobility all potentially impact the mother–child bond.

Related Research

Prickett, K. C. (2020). Mothers' job loss and their sensitivity to young children's development. *Child Development*, *91*(6), 1970–1987. https://doi.org/10.1111/cdev.13398

Using the National Institute of Child Health and Human Development (NICHD) longitudinal Study of Early Child Care and Youth Development (SECCYD) dataset, which was started in 1991 with 1,364 infants from 10 locations across the United States, the researcher used autoregressive cross-lagged structural equation models to analyze data from the 1,211 mothers who engaged in the 36-month interview cycle. Four mediators were considered simultaneously: family income, work satisfaction, childcare transitions, and maternal depression. Although the analysis does not explain or control for all of the potential internal and external variables, findings from this analysis were threefold: (1) unexpected job loss, especially during the child's first year of life, was negatively associated with maternal sensitivity; (2) decreases in total family income and maternal depression are factors that explain the association between job loss and maternal sensitivity; and (3) maternal education level matters, with the strongest negative association between job loss and sensitivity seen in mothers who graduated high school or completed a GED but did not complete a bachelor's degree.

Relevance to Nursing Practice

Responsive parenting rooted in maternal sensitivity is a consistent predictor of short- and long-term child well-being. Considering the impact of myriad internal and external factors on maternal sensitivity is challenging. Targeting policy changes, specifically involving providing support for working mothers and reconsidering unemployment/maternal leave benefits, provides increased job stability. Intentional consideration and support of women and children at these vulnerable times decreases the negative impact of instability on maternal sensitivity and responsiveness.

MIDDLE ADULTHOOD

Developmental tasks for middle adulthood include:

- Accepting and adjusting to physical changes
- Attaining and maintaining a satisfactory occupational performance
- Assisting children to become responsible adults
- Relating to the spouse as a person
- Adjusting to aging parents
- Achieving adult social and civic responsibility

LATER MATURITY

Developmental tasks for later maturity include:

- Adjusting to decreasing physical strength and health
- Adjusting to retirement and reduced income
- Adjusting to death of a spouse
- Establishing an explicit affiliation with the person's age group
- Adjusting and adapting social roles in a flexible way
- Establishing satisfactory physical living arrangements

Recall **Mr. Logan**, the older man with the fractured hip described at the beginning of the chapter. Based on Mr. Logan's comments, the nurse could apply Havighurst's theory to conclude that Mr. Logan may be fluctuating between feelings of nonadjustment and feelings of acceptance of his declining health.

Roger Gould

Gould (1978), a psychiatrist trained in a psychoanalytic perspective, studied people between the ages of 16 and 60 years. He labeled the central theme for adults transformation and identified specific beliefs and developmental phases.

AGES 18 TO 22 YEARS: LEAVING THE PARENTS' WORLD

During the young adult years, individuals typically struggle with leaving their parents' world and challenging false assumptions from their childlike consciousness (e.g., "Only my parents can guarantee my safety."). However, these assumptions may be replaced with new false assumptions, such as, "Rewards will come automatically if I do what I am supposed to do."

AGES 22 TO 28 YEARS: GETTING INTO THE ADULT WORLD

Individuals in their 20s feel established as adults and separate from their families but believe they must still prove to their parents or guardians that they are competent, independent adults. They want to enjoy the present but build for the future.

AGES 29 TO 34 YEARS: QUESTIONING AND REEXAMINATION

Self-acceptance increases as the person's need to prove their competence disappears. Marriage and careers are generally well established, and young parents want to accept their own children for what they are becoming without imposing unnecessary rules. Questions about life in general are still present.

FIGURE 22-6. As her sons grow into young adults, this mom adapts to remain a positive influence in their lives. (*Source:* Used with

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

permission from Shutterstock. *Photo by Joe Mitchell.*)

AGES 35 TO 43 YEARS: MIDLIFE DECADE

Adults in this age group tend to continually look inward and question themselves, their values, and their life. They see time as having an end and believe they have little time left to shape the behavior of their adolescent children (Fig. 22-6). They may be critical of their own parents, blaming them for many of their own problems.

AGES 43 TO 50 YEARS: RECONCILIATION AND MELLOWING

At this phase, adults accept the reality of boundaries for the lifespan and believe that personalities are set. They are interested in an active social life, community service, friends, and spouse. Life is viewed as neither simple nor controllable, which may result in periods of passivity, rage, depression, and despair.

AGES 50 AND OLDER: STABILITY AND ACCEPTANCE

Previous patterns of reflection and contemplation generally result in increased self-approval and self-acceptance. Increased marital happiness and contentment are associated with seeing the spouse as a valued companion.

Daniel Levinson and Associates

Levinson et al. (1978) based their theory on the organizing concept of "the evolution of individual life structure" (p. 40). The theory centers on the belief that the cycle of life at any point in time is formed by the interaction of three components: the self (values, motives), the social and cultural aspects of the person's life (family, career, religion, racial/ethnic background), and the person's particular set of roles (husband, father, friend, student). When anything changes in one component, the whole life structure must then reorganize. According to Levinson and associates, there are three major phases in young and middle adult life: novice, settling down, and midlife transition.

NOVICE PHASE

Early Adult Transition

The major concerns of the young adult (ages 17 to 22 years) are to break away from their parents or guardians, make initial career choices, and establish intimate relationships. Many separations, losses, and transformations are necessary to terminate old relationships. This is also a time to begin to select personal values and establish goals, as the young adult's life structure begins to be more integrated.

Box 22-3 **Key Points of Moral and Faith Developmental Theories**

Kohlberg: Moral Development

Preconventional, stage 1: Punishment and obedience—Oriented to obedience and punishment; right and wrong defined by punishments

Preconventional, stage 2: Instrumental relativist—Defines acts satisfying to self (and some satisfying to others) as right

Conventional, stage 3: Interpersonal concordance—Morality of maintaining good relations and approval of others; right and wrong are determined by the majority

Conventional, stage 4: Law and order—Being good extends to a person's duty to society; aware of need to respect authority

Postconventional, stage 5: Social contract—Right and wrong determined by personal values; laws are considered, but may be ignored or discounted

Postconventional, stage 6: Universal ethical principle—Deeply held moral principles are in accordance with a sense of self and are more important than laws; few adults ever reach this stage of development

Fowler: Faith Development

Fowler's six stages may occur over the course of a person's adult life.

Prestage: Undifferentiated faith—Centers on relationship with primary caregiver and the safety of the environment

Stage 1: Intuitive-predictive faith—Imitates religious behaviors of others; learning also occurs through stories and images

Stage 2: Mythic-literal faith—Accepts existence of deity; strong belief in justice; metaphors and symbolism often taken literally

Stage 3: Synthetic-conventional faith—Selection of principles to follow; development of a personal identity; concern for the rights and needs of others

Stage 4: Individuative-reflective faith—Angst possible; personal accountability for beliefs and feelings;

awareness of conflicts in the complexities of faith
Stage 5: Conjunctive faith—Conflicts resolved; identification of truth
Stage 6: Universalizing faith—Enlightenment; universality of faith and principles

Entering the Adult World

The years of the middle to late 20s (ages 22 to 28 years) are a time to build on previous decisions and choices, and to try different careers and lifestyles. By the late 20s, the young adult enters the age-30 transition period. The person often feels uneasy that something is missing. During this transition, decisions are made either to find a new direction in life or to make a stronger commitment to previous choices.

Age-30 Transition

This represents a transition time (ending around age 33 years) during which the overriding task of the novice phase—to establish a place in the world and create a viable, suitable life structure—is evaluated. This time of reflection allows for reconsideration of choices and the opportunity to make changes.

SETTLING DOWN: BUILDING A SECOND ADULT LIFE STRUCTURE

In the settling-down phase (ages 33 to 40 years), the adult invests energy into the areas of life that are most personally important. The areas of investment are primarily family, work, and community. The person strives to gain respect, status, and a sense of authority.

MIDLIFE TRANSITION AND ENTERING MIDDLE ADULTHOOD

Midlife Transition

Midlife transition (ages 40 to 45 years) involves a reappraisal of goals and values. The person's established lifestyle may continue, or they may choose to reorganize and change careers. This is an unsettled time, with the person often anxious and fearful. There is a focus on leaving a legacy and how short life is.

Entering Middle Adulthood

By this time (ages 45 to 50 years), the person has made choices and formed a new life structure. This allows for time to commit to new tasks.

Theories of Moral Development

Lawrence Kohlberg

Kohlberg (1969) developed a theory of **moral development** using levels that closely follow Piaget's theory of cognitive development (Box 22-3). Kohlberg recognized that a person's moral development is influenced by culture. Culture and sociocultural obligations affect the person's perceptions of justice in interpersonal relationships. A child's beginnings of moral development result from caregiver–child communications during the early childhood years, as the young child tries to please their parents and other caregivers (Fig. 22-7). The concept of morality emerges as a subset of a person's beliefs or values and governs choices made throughout life. Kohlberg's stages of moral development begin in childhood but may develop well into adolescence and adulthood. Rules and regulations established by society are eventually challenged and evaluated as a person either accepts societal rules into their own internal set of values or rejects them.

Remember **Juan**, the 8-year-old with encephalitis. Juan's language barrier and cultural heritage may be adding to the child's already heightened fears and anxieties related to hospitalization. The nurse's astute observation and application of Kohlberg's theory can further an understanding of the child's perceptions, beliefs, and, ultimately, his choices and actions.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 22-7. This grandfather reads traditional stories to their young granddaughter, teaching her important cultural values and beliefs, thereby influencing her moral development. (*Source:* Used with permission from Shutterstock. *Photo by Joe Mitchell.*)

PRECONVENTIONAL LEVEL

Kohlberg's preconventional level of moral development is based on external control, as the child learns to conform to rules imposed by authority figures. At stage 1, *punishment and obedience orientation*, the motivation for choices of action is the fear of physical consequences of authority's disapproval. As a result of the consequences, a perception of goodness or badness develops. At stage 2, *instrumental relativist orientation*, the thought of receiving a reward overcomes fear of punishment, and thus actions that satisfy this desire are selected.

CONVENTIONAL LEVEL

The conventional level of moral development involves identifying with significant others and conforming to their expectations. The person respects the values and ideals of family and friends, regardless of consequences. In stage 3, *"good boy–good girl" orientation*, the person strives for approval in an attempt to be viewed as good. At stage 4, *law and order orientation*, behavior follows social or religious rules from a respect for authority. In his later work, Kohlberg maintained that many adults are at this stage because they think abstractly and view themselves as members of society.

POSTCONVENTIONAL LEVEL

The postconventional level of moral development involves moral judgment that is rational and internalized as standards or values. At stage 5, *social contract and utilitarian orientation*, correct behavior is defined in terms of society's laws. These laws can be changed to meet society's needs, as long as they support respect for self and others. Stage 6, *universal ethical principle orientation*, represents the person's concern for equality for all human beings, guided by personal values and standards, regardless of those set by society or laws. Justice maybe internalized at an even higher level than society's level. Few adults ever reach this stage of development.

Carol Gilligan

Gilligan (1977, 1982) originally worked with Kohlberg. As she listened to women discuss their own real-life moral conflicts, she recognized that there was a conception of morality from the female viewpoint that was not represented in Kohlberg's work. Gilligan's theory views girls and women as developing a morality of response and care, and boys and men as developing a morality of justice. Gilligan's work must be considered within the context of gender roles and feminism of the 1970s and 1980s.

In Gilligan's theory, men and women have different ways of looking at the world. Men are more likely to associate morality with obligations, rights, and justice, whereas women are more likely to see moral requirements emerging from the needs of others within the context of a relationship. This moral orientation of women is called the *ethic of care*, which develops through three levels. Each level ends with a transitional period, a time when the girl or woman considers new approaches to moral considerations and moves to a new level.

LEVEL 1—PRECONVENTIONAL: SELFISHNESS

In level 1, the focus is on the girl's or woman's own needs. *Should* and *would* are the same. Morality is seen in terms of sanctions by society. Relationships are often disappointing, and as a result, a woman may isolate herself to avoid getting hurt. The transition that follows this level is characterized by the move from selfishness to responsibility—a move that

integrates the responsibility to care for oneself with the desire to care for others.

LEVEL 2—CONVENTIONAL: GOODNESS

In level 2, moral judgment is based on shared norms and expectations, and societal values are adopted. Acceptance by others becomes critical, and the ability to protect and care for others becomes the defining characteristic of female goodness. This goodness involves self-sacrifice and bearing responsibility for others. As a woman examines her self-sacrifice, the second transition occurs, with the woman asking if her own needs are not also important. A shift from *goodness* to *truth* (as well as a new conception of goodness) takes place.

Think back to **Ms. Kimber**, the single mother. The nurse could apply Gilligan's theory to assist Ms. Kimber in adjusting to her role as both a single parent caring for a child and as a woman with her own set of needs.

LEVEL 3—POSTCONVENTIONAL: NONVIOLENCE

In level 3, a changed understanding of self and a redefinition of morality allow reconciliation of selfishness and responsibility. Nonviolence (the injunction against hurting) governs all moral judgments and actions. Care becomes a universal obligation toward self and others. Moral problems are usually considered within the contexts of maintaining relationships and promoting the welfare or preventing the harm of others.

Theory of Faith Development

James Fowler

Fowler (1981, p. 4) postulated a developmental theory of the spiritual identity of humans, based on work by Piaget, Kohlberg, and Erikson. Fowler describes **faith** as follows:

> Faith is not always religious in its content or context…Faith is a person's or group's way of moving into the force field of life. It is our way of finding coherence in and giving meaning to the multiple forces and relations that make up our lives. Faith is a person's way of seeing him or herself in relation to others against a background of shared meaning and purpose. Faith, therefore, is not necessarily religious, but it comprises the reasons one finds life worth living.

Fowler's theory is composed of a prestage and six stages of faith development (see Box 22-3 on page 586). The age when a certain stage occurs varies, but the sequence does not. Fowler explained that a relationship among self, shared causes or values, and others is the unifying factor in all stages, and that relationship is based on trust. Equilibrium, or a plateau in faith development, can occur at any stage from stage 2 and beyond.

PRESTAGE: UNDIFFERENTIATED FAITH

During the prestage, trust, courage, hope, and love compete with threats of abandonment and inconsistencies in the infant's environment. The strength of faith in this stage is based on the infant's relationship with the primary caregiver.

STAGE 1: INTUITIVE–PROJECTIVE FAITH

Intuitive–projective faith is most typical of the 3- to 7-year-old child. Children imitate religious gestures and behaviors of others, primarily their parents or guardians. They take on their elders' attitudes toward religious or moral beliefs without a thorough understanding of them. Imagination in this stage leads to long-lived images and feelings that they must question and reintegrate in later stages.

STAGE 2: MYTHICAL–LITERAL FAITH

Mythical–literal faith predominates in the school-aged child, who is having more social interaction. Stories represent religious and moral beliefs, and the child accepts the existence of a deity. The child can appreciate the perspectives of others as well as the concept of reciprocal fairness.

STAGE 3: SYNTHETIC–CONVENTIONAL FAITH

Synthetic–conventional faith is the characteristic stage of many adolescents. As the person experiences increasing demands from work, school, family, and peers, the basis for identity becomes more complex. The person has an emerging ideology but has not closely examined it until now. The person begins to question life-guiding values or religious practices in an attempt to stabilize their own identity.

STAGE 4: INDIVIDUATIVE–REFLECTIVE FAITH

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Individuative–reflective faith is crucial for older adolescents and young adults because they become responsible for their own commitments, beliefs, and attitudes. Many adults do not develop to this stage, and for some people, it does not emerge until they are in their 30s or 40s. Searching for self-identity that is no longer defined by the faith of significant others, is a primary concern.

STAGE 5: CONJUNCTIVE FAITH

Conjunctive faith integrates other viewpoints about faith into a person's understanding of truth. The person can see the real nature of their own beliefs. Along with this realization, the person observes the divisions of faith development among people.

STAGE 6: UNIVERSALIZING FAITH

Universalizing faith involves making tangible the values of absolute love and justice for humankind. The faith relationship is characterized by total trust in the principle of actively *being in relation* to others in whom we invest commitment, belief, love, risk, and hope, and in the existence of the future, regardless of what religion or image of faith is involved.

APPLYING THEORIES OF GROWTH AND DEVELOPMENT TO NURSING CARE

The complex and interrelated elements that contribute to human growth and development involve not only biophysical factors, but also factors of personality development. The theories summarized in this chapter help us understand cognitive, psychosocial, moral, and spiritual development. To understand the whole person, nurses need to evaluate all the components of growth and development to appreciate certain life events or concerns (Fig. 22-8).

Although these theories offer a great deal of insight into the processes of human growth and development, they do have some limitations. You need to consider these developmental theories within the context of when they were developed. Although they have sustained relevance, some concepts are based on assumptions and beliefs that may not hold true in today's world. We also have a more-nuanced understanding of disparities, vulnerabilities, and social determinants of health that impact on growth and development. When planning holistic nursing care for patients with diverse needs, backgrounds, and ages, nurses should assess the patient as an individual and use interventions based on rationales from multiple developmental theories to provide comprehensive health care. Watch for the Vulnerable Population Alerts and Challenging Topics throughout this text—take time to reflect and acknowledge your role in addressing issues that impact health equity. Guidelines for incorporating the principles and theories of growth and development in nursing care are listed in Box 22-4.

Health care needs change quickly as a person grows and passes through life. These needs are unique for each person but have certain similarities in specific developmental stages. The nurse must plan care based on the patient's general and unique health needs and must continually revise aspects of care as the growth process evolves or alterations in health status occur.

FIGURE 22-8. A. To provide holistic and individualized care, the nurse applies theories of growth and development when she displays compassion and provides emotional support to a young, hospitalized child. **B.** The nurse caring for an older adult includes the daughter, with whom the patient now lives, in discharge teaching. (*Source:* B: Used with permission from Shutterstock. *Photo by B. Proud.*)

The nurse is also uniquely positioned to address the sensitive emotional, psychological, and educational issues related

to genetic, genomic, and epigenetic discoveries. This focus on health rather than disease has the potential to result in significantly positive outcomes for the growth and development of all people.

Box 22-4 Incorporating Principles and Theories of Growth and Development

General guidelines for incorporating principles and theories of growth and development and family dynamics into daily practice of nursing care are listed here. They are provided as suggestions for working with patients of all ages.

- Be knowledgeable about the various stages of cognitive, psychosocial, moral, and spiritual development and prepared to support developmental stages typical of certain ages.
- Maintain flexibility in assessing patients and respect the uniqueness of each person. Although the literature describes development typical of a particular age, not everyone fits into an exact mold.
- Anticipate possible regression during difficult periods or times of crisis, then accept and support a person's return to a forward progression in development.
- Understand that environmental and cultural influences have a strong effect on development, especially psychosocial development. A deprived environment can be detrimental, whereas an enriched environment enhances development.
- Assess each person with an awareness that within each stage of development, a person may retain some behaviors of a previous stage, attain goals of the current stage, and begin to exhibit behaviors of the next stage. There is a time of transition to the next stage with no definitive beginning or ending.
- Remember that patients are members of families, and that the family can have both positive and negative influences on the development of individual members. Keep in mind that *family* is whomever the person identifies as family. Attempt to support good family relationships and healthy environments that assist members to reach their greatest potential for growth. Provide patient teaching to individuals and their families to aid in their understanding of periods of development.
- Be ready to provide health care to patients who are ill or who fail to meet developmental goals. Collaborate with other members of the health care team in providing care to prevent or minimize disruption of development and to promote optimal health throughout life.
- Provide environments and experiences that are developmentally challenging.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Identify developmental challenges for five of your family members or friends at different ages across the lifespan. Explain why meeting developmental needs is an essential role of nursing.
. Compare and contrast the psychosocial theories of Erikson and Gould. Are the concepts in these theories relevant today? If yes, explain why. If no, what would you delete and what would you add?
. Using Piaget's theory of cognitive development, describe how you would explain the death of a parent to children ages 4, 9, and 13 years.

PRACTICING FOR NCLEX

. A nurse assessing a toddler in a pediatric office tells the parents that the child is in the 90th percentile for height and weight and has blue eyes. The nurse explains these physical characteristics are primarily determined by which of the following?

a. Socialization with caregivers
b. Maternal nutrition during pregnancy
c. Genetic information on chromosomes
d. Meeting developmental tasks

. A nurse caring for newborns understands that babies grow and develop according to individual growth patterns and developmental levels. Which terms describe these patterns? Select all that apply.

a. Orderly
b. Simple
c. Sequential
d. Unpredictable
e. Differentiated
f. Integrated

. A 2-year-old grabs a handful of cake from the table and stuffs it in their mouth. According to Freud, what part of the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

mind is the child satisfying?

a. Id
b. Superego
c. Ego
d. Unconscious mind

. A nurse is teaching parents of preschoolers the types of behavior to expect from their children based on developmental theories. Which statements describe this stage of development? Select all that apply.

a. According to Freud, the child is in the phallic stage.
b. According to Erikson, the child is in the trust versus mistrust stage.
c. According to Havighurst, the child is learning to get along with others.
d. According to Fowler, the child imitates religious behavior of others.
e. According to Kohlberg, the child defines satisfying acts as right.
f. According to Havighurst, the child is achieving gender-specific roles.

. When caring for older adults in a long-term care facility, a nurse encourages an older adult to talk about past life events. One patient tells the nurse they were an angry person, lost many jobs, and ended up alone. According to Erikson, this patient is in what developmental stage?

a. Despair
b. Stagnation
c. Inferiority
d. Industry

. Nursing students attending a class on genomics are discussing its use in current nursing practice. Which statements by the students identify genetic principles that will challenge nurses to integrate genomics in their research, education, and practice? Select all that apply.

a. Genetic tests plus family history tools have the potential to identify people at risk for diseases.
b. Pharmacogenetic tests can determine if a patient is likely to positive therapeutic response to a drug or develop adverse reactions from the medication.
c. Evidence-based review panels are in place to evaluate the possible risks and benefits related to genetic testing.
d. Valid and reliable national data bases exist to establish baseline measures and track progress toward targets.
e. Genetic variation can either accelerate or slow the metabolism of many drugs.
f. It is beyond a nurse's scope of practice to discuss the impact of genetic findings and impact on health and illness.

. A nurse who is working with women in a drop-in shelter studies Carol Gilligan's theory of morality in women to use when planning care. According to Gilligan, what is the motivation for female morality?

a. Law and justice
b. Obligations and rights
c. Response and care
d. Order and selfishness

. A school nurse uses Kohlberg's theory of moral development as a basis for a roundtable discussion with parents on bullying. According to Kohlberg, what factor initially influences the moral development of children?

a. Parent/caregiver–child communications
b. Societal rules and regulations
c. Social and religious rules
d. A person's beliefs and values

. A school nurse uses Havighurst's principles and theories of growth and development when planning programs for high school students. With this information, the nurse can assist students to correlate their behavior and decisions to which age-appropriate developmental task?

a. Finding a congenial social group
b. Developing a conscience, morality, and a scale of values
c. Achieving personal independence
d. Achieving a masculine or feminine gender role

. While assessing a patient in the medical clinic, the patient tells the nurse: "I'm currently a sales associate, but I'm considering a career move, which makes me somewhat anxious." According to Levinson, what phase of adult life is this patient experiencing?

a. Entering the adult world
b. Settling down

c. Midlife transition
d. Entering middle-adulthood

. When teaching parents about achievements in children, the nurse explains that, according to Piaget, children in which age group are able to grasp abstract ideas?
a. Toddler
b. Adolescence
c. Preschool age
d. School age

. A parent shares with the nurse in the pediatric clinic that their 12-month-old cries when they leave the room or hide a favorite stuffed animal. The nurse explains that object permanence typically occurs in which group?
a. 0 to 6 months
b. 12 to 18 months
c. 24 to 36 months
d. 36 months to 4 years

. A nurse working in a hospice setting uses reminiscence to help patients determine whether their life had meaning or if they wish to make amends. What stage of Erickson's development is the nurse applying with this approach?
a. Industry versus inferiority
b. Initiative versus guilt
c. Generativity versus stagnation
d. Ego integrity versus despair

ANSWERS WITH RATIONALES

. **c.** Physical appearance and growth have a predetermined genetic base in inheritance patterns carried on the chromosomes.

. **a, c, e, f.** Growth and development are orderly and sequential as well as continuous and complex. Growth and development follow regular and predictable trends and are both differentiated and integrated.

. **a.** Freud defined the id as the part of the mind concerned with self-gratification by the easiest and quickest available means.

. **a, d, e.** According to Freud, the child is in the phallic stage. According to Fowler, the child imitates religious behavior of others. According to Kohlberg, the child defines satisfying acts as right. According to Erikson, the child is in the initiative versus guilt stage. According to Havighurst, the child is learning sex differences, forming concepts, and getting ready to read. According to Havighurst, the adolescent, not the preschooler, is achieving gender-specific social roles.

. **a.** Reminiscence during the older years of a person's life provides a sense of fulfillment and purpose (ego integrity). Generativity versus stagnation is a developmental stage of the middle adult years. Industry versus inferiority states that if a child is not accepted by peers or cannot meet parental expectations, feelings of lack of self-worth may develop.

. **a, b, e.** Health care providers are being challenged to integrate genomics into their research, education, and practice. Genetic tests plus family history tools have the potential to identify people at risk for diseases. Pharmacogenetics studies how genetic variation affects a person's response to drugs, helping to determine if a patient is likely to have a strong therapeutic response or develop adverse effects to a drug. Genetic variation can either accelerate or slow the metabolism of many drugs (see Chapter 30). The need for (1) evidence-based review panels to thoroughly evaluate the possible benefits and harms related to the expanding number of genetic tests and family health history tools; and (2) valid and reliable national data to establish baseline measures and track progress toward targets (Office of Disease Prevention and Health Promotion, 2021) are emerging challenges in genomics. Nurses must be prepared to answer questions and discuss the impact of genetic findings on health and illness.

. **c.** In Gilligan's theory, men and women have different ways of looking at the world. Women typically see moral requirements emerging from the needs of others within the context of a relationship. This moral orientation of women is called the *ethic of care*, which develops through three levels: Level 1—Preconventional: Selfishness, Level 2—Conventional: Goodness, Level 3—Postconventional: Nonviolence. Men typically associate morality with obligations, rights, and justice.

. **a.** The beginnings of moral development result from parent/caregiver–child communications during early childhood, as the young child tries to please parents and caregivers. Kohlberg's stages of moral development begin in childhood but may continue developing into adolescence and adulthood. Rules and regulations established by society are eventually challenged and evaluated as a person either accepts societal rules into his or her own internal set of values or rejects them.

. **d.** According to Havighurst, the role of the adolescent is to achieve a masculine or feminine gender role. Developing a

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

conscience, morality, and a scale of values and achieving personal independence are roles of middle childhood. Finding a congenial social group is a role of young adulthood.

. **c.** Midlife transition (ages 40 to 45 years) involves a reappraisal of goals and values. The established lifestyle may continue, or the person may choose to reorganize and change careers, creating anxiety or fear. In the middle to late 20s (ages 22 to 28 years) young adults build on previous decisions and choices and to try different careers and lifestyles. In the settling-down phase (ages 33 to 40 years), the adult invests energy into the areas of life that are most personally important. The years of entering middle adulthood (ages 45 to 50 years) revolve around having made choices and having formed a new life structure, and committing to new tasks.

. **c.** According to Piaget's preoperational stage, increased language, increased understanding of life events, and relationships occur with language greatly increasing from ages 3 to 5 years.

. **b.** Object permanence typically develops at age 12 to 18 months.

. **d.** Reminiscence for the older adult provides a sense of fulfillment and purpose (integrity), perhaps removing the fear of dying. A sense of despair may ensue if a person believes that their life has been a series of failures or missed directions. Preschoolers (ages 4 to 6 years) take the initiative in learning and seeking out new experiences; when experiencing restrictions or reprimands, they typically hesitate to attempt more challenging (initiative vs. guilt). The school-aged child enjoys finishing projects and receiving recognition for accomplishments; children who are not accepted by peers or cannot meet parental expectations develop feelings of inferiority and lack of self-worth may develop (industry vs. inferiority). Middle adult years are marked by involvement with family, friends, community, and concern for the next generation; if this task is not met, stagnation occurs, and the person becomes self-absorbed or regresses to an earlier level of coping (generativity vs. stagnation).

23

Conception Through Young Adulthood

Nate Pelton

Nate, who is 11 years old, collided with another player while running in the outfield during a Little League baseball game. He was removed from the game after the collision because he reported a headache and, according to his coaches, appeared slightly dazed. His parents took him to the emergency department at the local hospital where Nate told the ED nurse, “I felt a little dizzy after the collision, but I feel fine now.”

Darlene Schneider

Darlene, a pregnant 14-year-old in her third trimester, comes to the prenatal clinic for the first time. Her history reveals sexual activity with multiple partners, smoking two packs of cigarettes per day, beer “four or five nights a week,” and eating mostly “fast foods.” She has received no prenatal care and hasn’t been taking any prenatal vitamins. She is experiencing homelessness but occasionally stays with an older girlfriend since her parents “threw me out of the house.”

Hillarie Browning

Hillarie, who is 2 years old, is brought to the emergency department by her father, James Browning. She is unresponsive. Mr. Browning says that she “took a tumble” down the stairs, but assessment reveals that her injuries are inconsistent with this type of fall.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Summarize major physiologic, cognitive, psychosocial, moral, and spiritual developments from conception through young adulthood.
. Apply specific theoretical models and theories to each developmental period from conception to young adulthood.
. List common health problems of each age period from conception through young adulthood.
. Describe developmental and situational stressors common in each developmental period from conception to young adulthood.
. Describe nursing interventions to promote health in patients from conception through young adulthood.

Nursing Concepts

sudden infant death syndrome (SIDS)
sudden unexpected infant death (SUID)
temperament
toddler
young adult

Growth and development start at conception and continue over the course of a person's life. The nurse's knowledge of growth and developmental milestones provides a base for planning and implementing holistic, individualized nursing care. This chapter continues the discussion of developmental theories introduced in Chapter 22, with specific information related to the sequential stages of growth and development from conception through young adulthood.

Childhood encompasses the entire period before young adulthood and is divided into different stages. Included within this time span are the fetus, neonate, infant, toddler, preschooler, school-aged child, and adolescent. This chapter's discussion of each of these stages, as well as the period of young adulthood, includes physiologic, cognitive, psychosocial, and moral and spiritual development, as appropriate. We will also explore the nurse's role in promoting and maintaining health with each group of children and young adults. For an example that addresses the adolescent, see the Reflective Practice box.

CONCEPTION AND PRENATAL DEVELOPMENT

Human growth and development begin the moment the ovum is fertilized by the sperm. The fertilized ovum (zygote) contains the full complement of genetic information provided by each parent that determines biologic sex and influences personality, intellect, physical traits, and psychological traits. The growth and development stages of the fetus are orderly and continuous.

Pre-embryonic Stage

The pre-embryonic stage lasts for about 3 weeks. The zygote, which implants in the uterine wall, has three distinct cell layers. The endoderm (inner layer) becomes the respiratory system, the digestive system, the liver, and the pancreas. The mesoderm (middle layer) becomes the skeleton; connective tissue; cartilage; muscles; and the circulatory, lymphoid, reproductive, and urinary systems. The ectoderm (outer layer) becomes the brain, spinal cord, nervous system, and outer body parts (skin, hair, and nails).

Embryonic Stage

The embryonic stage occurs from the 4th through the 8th week. Rapid growth and differentiation of the cell layers take place. By the end of this stage, all basic organs have been established, the bones have begun to ossify, and some human features are recognizable. Because this is a period of such rapid growth and change, the embryo is especially vulnerable to any factor that might cause congenital anomalies (such as maternal use of alcohol, nicotine, over-the-counter [OTC] medications, or other drugs).

Fetal Stage

The fetal stage lasts from 9 weeks to birth. All body organs and systems continue to grow and develop. At the end of the first trimester (12 weeks' gestation), some reflexes are present, kidney secretion begins, the heartbeat can be heard by Doppler, and the sex of the fetus is distinguishable by outward appearance. At the end of the second trimester (24 weeks' gestation), fetal heart tones are able to be auscultated, the liver and pancreas are functioning, hair forms, sleep–wake patterns are established, lung surfactant is produced, and the eyelids open. At the end of the third trimester (40 weeks' gestation), the testes have descended, lung alveoli are formed, subcutaneous fat is deposited, and the fetus actively kicks. By birth, the average neonate weighs 7.5 lb (3.4 kg) and is 20 inches (50.8 cm) long.

During pregnancy, adequate maternal nutrition is essential for normal growth and development of the embryo and fetus. A fetus not receiving adequate nutrition may be small for gestational age, fail to have normal brain development, have learning disabilities as a child, and be at increased risk for chronic illnesses as an adult. Vitamin and mineral deficiencies can result in fetal megaloblastic anemia and neural tube defects (folic acid deficiency), inadequate bone calcification (vitamin D and calcium deficits), and hypothyroidism (iodine deficiency).

The number of premature births (those occurring before 37 weeks' gestation; also referred to as preterm births) decreased from 2007 to 2014 due in part to a decrease in the number of adolescents and young women giving birth. However, there was a slight increase in preterm births 5 years in a row between 2014 and 2019 (Centers for Disease Control [CDC], 2020c). Low birth weight is one of the leading causes of infant mortality and the leading cause of infant death during the first month of life. In 2018, 17% of infant deaths were related to preterm birth and low birth weight. Infants born preterm are at increased risk for disorders such as respiratory problems, feeding and digestive difficulties, cerebral palsy, developmental delay, and sensory problems such as vision or hearing impairment (CDC, 2020c). Racial and ethnic disparities persist in relation to preterm birth. In 2019, the rate of preterm births among non-Hispanic Black women (14.4%) was higher than the rate among non-Hispanic White women (9.3%) or Hispanic women (10%; CDC, 2020c). Many people, including health care workers, are unaware of the magnitude of the potential and actual problems associated with preterm birth.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

I was admitting Darlene Schneider, a pregnant, unmarried 14-year-old, to the prenatal clinic. This was her first visit, and she was already in her third trimester. A quick history revealed multiple factors putting both her and her fetus at risk for health problems: lack of family support (experiencing homelessness, occasionally staying with an older friend), father of the baby unknown, multiple sexual partners, diet consisting mainly of fast food, no prenatal vitamins, little to no exercise, and history of smoking (two packs of cigarettes per day) and alcohol consumption ("beer four to five times a week"). When she was seen by the medical resident, he asked her quite curtly if she was trying to kill her baby, telling her that it was probably too late for her to get the care she needed. "Why should we waste our time on you when other women here really want to be helped?" Although Darlene was trying to hide her emotions, I could tell from her expression that she was both angry and hurt. While I shared some of the resident's frustration, I knew

we had to give Darlene a reason to trust us if we wanted her to start taking better care of herself and her fetus. I was also upset by the resident's lack of professionalism and wondered if I should say something to him.

Thinking Outside the Box: Possible Courses of Action

- Take advantage of the resident having been so harsh: after the resident finished his visit, I could try to be especially caring and explain why we were all concerned about her and her fetus. Then I could talk to her about what she needed to do to maximize good outcomes.
- Challenge the resident in the patient's presence, thereby showing her that at least I honestly cared about her.
- Confront the resident later in a moment when my emotions are not running so high, and directly address the issue. I would also indicate that although I am hopeful change will occur, I am prepared to report my concerns to a supervisor should this behavior occur again.
- Approach the resident outside the patient's presence and explain my concerns. Persuade the resident to apologize to Darlene in the interests of winning the patient's trust and compliance with the prenatal care program.

Evaluating a Good Outcome: How Do I Define Success?

- The respect for each person's human dignity (Darlene, the resident, myself) is affirmed.
- Each person feels empowered to make personal decisions that advance their interests and goals.
- The patient makes the needed lifestyle changes, with good outcomes for herself and her fetus.
- Personal integrity is maintained; no one has to sacrifice beliefs and values.
- Professional integrity is maintained.

Personal Learning: Here's to the Future!

In this situation, I don't think that I chose the best alternative because I tried to comfort Darlene and make excuses for the resident's behavior. I tried to explain that the resident was very busy and simply "out of sorts." I have to admit that, initially, I was probably just as shocked by the resident's response as Darlene. I did speak to the resident alone later and learned that this tactic was intentional. The resident had previous success with what he referred to as a form of "tough love" that involves shocking a patient into compliance. However, in this encounter, Darlene had no way of knowing that his response was well intended, and it was wholly unsuccessful. The resident ignored communication cues and did not take Darlene's specific circumstance into consideration. While talking further with Darlene, I became convinced that she wouldn't start hearing us until she could trust us. I wish I had had the courage to ask the resident to apologize to Darlene. His apology might have been exactly what was needed to get her to trust us, but that was not going to happen. I knew that I needed to work even harder to establish a trusting relationship with Darlene. Although this encounter did negatively affect this process, I needed to move forward and do my best to give Darlene and her fetus their best chance at a positive outcome. I'm learning that when patient welfare is at stake, I may have to sacrifice my own comfort level to challenge other professional caregivers and take the lead when the patient's relationship with the health care team is at risk. Hopefully, I'll learn how to do this in a way that promotes respectful, collaborative relationships.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and the adequacy of your skills for professional practice? Can you think of other ways to respond? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety when caring for patients like Darlene?

Patient-Centered Care: What information should be communicated to Darlene regarding concerns about her pregnancy and the developing fetus? How could you involve the patient as a partner in coordinating her care to promote trust? How might you talk with Darlene about the various risk factors contributing to her health and that of her fetus? What is the best way to communicate emotional support to Darlene?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to continue to function as a resource and advocate for Darlene? What if the nurse confronted the resident in front of the patient? Would you consider this professional behavior? Do you feel that the resident functioned in a professional manner? What is your role in facilitating the ongoing professional development and education

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of the resident? How will your constructive feedback make a difference? Do you agree with the nurse in the thinking that an apology from the resident would help encourage Darlene to trust health care professionals? Why or why not? Are there other community resources that may help Darlene in the care of her baby following the baby's birth?

Safety/Evidence-Based Practice: Is there anything more you could have done to acknowledge you understand Darlene's reasons for lack of trust and possible unwillingness to make changes to promote a positive outcome? How might a nurse's developmental stage have affected the actions taken toward the resident and the patient? What evidence in nursing literature provides guidance for decision making regarding ensuring a safe environment and giving Darlene the support that she needs?

Informatics: Can you identify essential information that must be documented in Darlene's electronic record about efforts to communicate with her and the specific concerns that she expressed? What other information must be available to support safe care for Darlene and her fetus and coordination of her care? Can you think of other ways to respond or approach the situation?

Other health risks for the developing fetus are discussed later in this chapter.

NEONATES: BIRTH TO 28 DAYS

At birth, the **neonate** must adapt to extrauterine life through several significant physiologic adjustments. The most important adjustments occur in the respiratory and circulatory systems as the neonate begins breathing and maintains circulation independent of the umbilical cord. The neonate is assessed immediately after birth. Of several existing measurement scales, the Apgar (1953) rating scale is the most commonly used tool for standardized assessment. This scale is used to assess neonates 1 and 5 minutes after birth (Table 23-1). An expanded Apgar score reporting form that includes ongoing assessment at 10, 15, and 20 minutes is recommended (as needed) to document resuscitative interventions (American College of Obstetricians and Gynecologists, 2015/2021).

Table 23-1 Apgar Scoring Chart

Category[a]	0	1	2
Heart rate	Absent	<100 beats/min	>100 beats/min
Respiratory effort	Absent	Slow, irregular	Good, crying
Muscle tone	Flaccid	Some flexion of extremities	Active motion
Reflex irritability	No response	Weak cry or grimace	Vigorous cry
Color	Blue, pale	Body pink, extremities blue	Completely pink

[a]Each category is rated as 0, 1, or 2. The rating for each category is then totaled to a maximum score of 10. Normal neonates score between 7 and 10. Neonates who score between 4 and 6 require special assistance; those who score below 4 are in need of immediate life-saving support.

Physiologic Development

The physical characteristics and behaviors of normal neonates are as follows:

- Reflexes include the Moro reflex, the stepping reflex, grasp reflex, hand-to-mouth activity, sucking, swallowing, blinking, sneezing, and yawning (Fig. 23-1).
- Body temperature responds quickly to the environmental temperature.
- Senses are used to respond to the environment; see color and form; hear and turn toward sound, smell, and taste; and feel touch and pain.
- Stool and urine are eliminated.
- Both an active crying state and a quiet alert state are exhibited (see Fig. 23-1).

The neonate inherits a transient immunity from infections as a result of maternal immunoglobulins that cross the placenta. Breastfeeding provides further protection against bacterial and viral infections through antibodies, immunoglobulins, and leukocytes in breast milk. The high lactose content in breast milk, combined with limited protein, promotes an acid environment that is unsuitable for bacterial growth. The American College of Obstetricians and Gynecologists (ACOG, 2018) recommends exclusive breastfeeding for the first 6 months of life, with continued breastfeeding, complemented by the introduction of solid foods, through the first year of life or for as long as mutually

desired by the person breastfeeding and the infant.

FIGURE 23-1. Reflexes and behaviors of the neonate. (*Source:* A, B, D, F. Used with permission from Shutterstock. *Photos by Joe Mitchell*.)

Health of the Neonate

Difficulties related to the birth process, the transition to extrauterine life, or congenital anomalies may require intervention by health care personnel.

Respiratory difficulties may occur, especially if drugs given to the birthing person during labor and delivery have sedated the neonate. Premature neonates are vulnerable to respiratory distress syndrome because of their relatively immature lung function. Neonates delivered by cesarean birth are at risk for respiratory difficulties because of excess mucus in the lungs and may require frequent suctioning.

Incompatibility between the neonate's and birthing person's blood groups (Rh factor) requires prompt care at birth. Congenital malformations, such as cleft palate and cleft lip or neural tube defects (such as spina bifida) and hydrocephalus, may result in long-term health problems. When there are birth traumas that cause temporary symptoms —for example, caput succedaneum (localized edema of the scalp), molding (elongation of the skull as the baby passes through the birth canal), and subconjunctival hemorrhage—the parents and caregivers need to be reassured that the symptoms will disappear. The nonthreatening nature of physiologic jaundice, which commonly occurs in the neonate's first days, should also be explained to the parents and caregivers.

Neonates born to birthing persons who smoke cigarettes, drink alcohol, or use drugs are at risk for developmental deficits as well as complications during birth. Smoking during pregnancy can lead to preterm birth, low birth weight, certain birth defects, and infant death (CDC, 2020b). Fetal alcohol spectrum disorders (FASDs) caused by a birthing person's drinking include a range of neurodevelopmental disorders involving neurocognitive, neurobehavioral, and neuropsychological components; learning disorders and difficulties at school; growth disorders; and characteristic facial features (Oei, 2020; Schölin et al., 2021). A newly proposed mental health diagnosis in the *Diagnostic and Statistical Manual, Fifth Edition* (DSM-5), the standard reference for clinical diagnosis and practice for the field of mental health, includes Neurobehavioral Disorder associated with Prenatal Alcohol Exposure (ND-PAE). This diagnosis applies to

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

children with a known exposure to alcohol in utero who present with impairment in neurocognition (general, executive functioning, learning, memory, visual–spatial reasoning), impairment in self-regulation (mood, behavior, attention, impulse control), and adaptive dysfunction in two areas (communication, social, daily living, motor), that are not explained by other factors (Hagan et al., 2016; Kable & Mukherjee, 2017).

Bonding might occur in the first few hours after birth or later in the first few months and is necessary for later attachment.

As the infant enters the second half of her first year, play will begin to involve manipulation of objects and the environment.

Developmental tasks of the first year include eating solid food.

Later infancy is characterized by the ability to pull-to-stand, cruise, and often walk.

FIGURE 23-2. Development in the infant. (*Source:* A. Used with permission from Shutterstock. *Photo by Joe Mitchell*. B. Used with permission from Shutterstock. *Photo by Oksana Kuzmina*. D. Used with permission from Shutterstock. *Photo by Blend Images*.)

INFANTS: 1 MONTH TO 1 YEAR

The neonate becomes an **infant** at 1 month, with the period of infancy lasting until the first birthday (Fig. 23-2).

Physiologic Development

The physical characteristics of the infant include the following:

- The brain grows to about half the adult size.
- Body temperature stabilizes.
- Motor abilities develop, allowing the infant to use building blocks, to attempt to feed themselves, and eventually to crawl and walk.
- The eyes begin to focus and fixate.
- The heart doubles in weight, the heart rate slows, and blood pressure rises.
- Deciduous teeth begin to erupt at 4 to 6 months.

- Birth weight usually triples by 1 year, when the average male infant weighs 22 lb (10 kg) and the average female infant weighs 21 lb (9.5 kg); length increases by 50%.

Cognitive Development

Infants from birth to 1 year are in the sensorimotor stage of development described by Piaget (Piaget & Inhelder, 1969). Language development is in the prelinguistic phase. Babies begin to coo and make sounds soon after birth, and by age 12 months, they can convey their wishes through a few key words. Language development in infants has several consistent characteristics that occur with all languages:

- Use of syllable repetition (such as ma-ma, da-da, bye-bye)
- Universal early phonetic expressions (babbling sounds)
- Imitation of sounds and intonations spoken by caregivers

Psychosocial Development

Developmental Theories

The developmental theories discussed in Chapter 22 describe the infant as having the following characteristics:

- *Freud's theory* (1960): The infant is in the oral stage, striving for immediate gratification of needs and having a strong sucking need.
- *Erikson's theory* (1963): The infant develops trust if the caregiver can be counted on to provide food when the infant is hungry; trust is also facilitated by diaper changing, warmth, and comforting.
- *Havinghurst's theory* (1972): The infant meets developmental tasks by learning to eat solid food, walk, and talk.

Special Considerations

Other components of psychosocial development in the neonate and infant include attachment, bonding, play, and temperament.

ATTACHMENT AND BONDING

Attachment is an active, affectionate, reciprocal relationship between two people, which is somewhat different from bonding. **Bonding**, described by Klaus and Kennell (1982), occurs during a sensitive period in the first few hours after birth (although bonding also may occur later in the first few months) and is necessary for later attachment. Bonding may be considered the emotional linkage of two people, while attachment is considered the long-term maintenance and strengthening of that linked state. Physical (skin-to-skin) contact is a component of attachment research. Maternal proximity may influence the socioemotional development of the infant, and have positive effects on the infant's sleep patterns, internal body regulation, behavioral responses, development of colic (crying), speech development, trauma resilience, and their physical health as adults (Norholt, 2020).

PLAY

Infants and children discover their environment and begin to learn how to control it through play. Beginning as soon as the baby is aware of sensations and the enjoyment they produce, play progresses from entertaining oneself to interaction with others. The two dimensions of play are social play and cognitive play. Social play, such as rolling a ball back and forth between two children, is motivated by a desire for fun, pleasure, and engagement with others. Cognitive play, like when a child puts a puzzle together, is motivated by the desire to learn.

TEMPERAMENT

Temperament is primarily inborn, although it is influenced by environment. A baby or child may be said to be "easy," "slow to warm," or "difficult" (Thomas et al., 1968). The *easy* infant sleeps, eats, and eliminates easily; smiles spontaneously; and cries in response to significant needs. The *slow-to-warm* infant is more passive and distant. The *difficult* infant has volatile and labile responses, often is a restless sleeper, is highly sensitive to noises, and eats poorly. These traits often remain fairly consistent throughout the person's life. The behavior of caregivers as they care for the baby can positively or negatively influence the degree to which temperament dictates behavioral style.

Health of the Infant

Various health problems in infancy may require the intervention of health care personnel. Gastroenteritis and food allergies are common. Skin disorders, such as diaper dermatitis (diaper rash), seborrheic dermatitis (infant dandruff), prickly heat rash, acute infantile eczema, and oral thrush (infection of the oral mucous membrane by the fungus *Candida albicans*), are also common. Infant colic, failure to thrive, accidents, sudden infant death syndrome (SIDS), and child maltreatment are of particular concern during infancy.

Infant Colic

Colic is often described using *Wessel's rule of threes* that involves inconsolable crying or fussing in an infant that lasts more than 3 hours, occurs more than 3 days per week, and lasts for more than 3 weeks, although the duration was

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

changed to 7 days in the modified Wessel's criteria (Hjern et al., 2020; Wolke et al., 2017). A recent update to the Rome IV criteria (established by gastroenterology experts) counters that the 3-hour designation may be arbitrary and culturally dependent, and that the inability to console or soothe the infant was a key element (Hjern et al., 2020; Zeevenhooven et al., 2017). Periods of colic are more frequent the first 6 weeks of life (17% to 25%) and then decrease between 6 and 12 weeks of life (11%, then down to 0.6% at 10 to 12 weeks; Wolke et al., 2017). This continuous crying can occur at any time but usually worsens in the evening. The infant cries loudly and draws the legs up to the abdomen. Despite the symptoms, the infant gains weight, and a change in feeding type or process does not improve colic. Although *Lactobacillus reuteri* DSM 17938, a probiotic, shows promise in the treatment of colic, acupuncture has not proven to be effective (Hjern et al., 2020). Parents, caregivers, and other family members may experience stress and anxiety due to the constant crying (de Kruijff et al., 2021; see Through the Eyes of a Caregiver).

Through the Eyes of a Caregiver

When my son Luke was first born, he was an easy-going, pleasant baby. Then, when he was about 3 weeks old, it started. He cried inconsolably every night from 5 PM until 12 AM. We could do nothing to comfort him. We took him to the pediatrician. The doctor said the word we already expected to hear: "colic." He gave us a prescription for an antacid and a muscle relaxant. He gave us some advice on how to comfort him … wrap him snugly, hold him like a football, eliminate milk and dairy from my diet (I was breastfeeding), and put pressure on his belly. None of these things worked. Eventually, we discovered that rocking him in our arms as we ran the shower seemed to calm him. Pink Floyd and *Dark Side of the Moon* also comforted him. We found this out quite accidentally when we played the vinyl record in an attempt to drown out his crying. These methods somewhat helped with the crying but did little to help my anxiety. I was concerned for my little son, who was clearly upset or maybe even in pain. At the same time, I found it very difficult to bond with him. I'd find myself dreading the evening, dreading being with my baby. When I'd come home from work, I'd take a deep breath and stand paralyzed at the front door, wondering if I had to go in. I could hear his crying from the doorstep. I felt horrible about these feelings. I questioned my parenting skills. At one point, I spoke with a nurse whose daughter had colic. She said, "My daughter's colic lasted 100 days, but it has taken me 14 years to forgive her!" This made me laugh for the first time in weeks. Then she asked how I was doing and if I wanted to talk about how I was feeling. I hadn't told anyone how I was feeling toward my son. How could I? I confided in her, though. I knew she wouldn't judge me. I knew she'd understand. After speaking with the nurse, I felt a lot better knowing that it was OK to feel the way I did. As time went on, Luke's crying spells got shorter and shorter, until the 99th day; then, miraculously, it ended. We had a party the next day, with a cake that said "Day 100. We made it." Today, he is a sweet, healthy child. He is no fussier than any other 3-year-old child. We have bonded exceptionally well. My husband and family were supportive and helped care for Luke when he had colic, but it was the nurse who helped care for me!

—Dana Jameson, Philadelphia, PA

Failure to Thrive

Failure to thrive (FTT) is a condition of inadequate growth in height and weight resulting from the infant's inability to obtain or use calories needed for growth. Collection of serial height, weight, and head circumference measurements on a reference scale such as a growth chart are helpful in determining this clinical finding (Homan, 2016). Infants with prolonged severe malnutrition may show signs of compromised cognitive and immune function, and may not meet developmental milestones (Franceschi et al., 2021). Causes and contributing factors most commonly include malnutrition or inadequate caloric intake but may also include organic causes such as gastrointestinal and genetic diagnoses. Contributing factors may include neglect or abuse, maternal education level, poverty, poor parenting skills, psychosocial family issues, and unusual health or nutritional beliefs (Franceschi et al., 2021; Homan, 2016). In most cases of FTT not caused by a physiologic problem, a team of health care providers is needed to meet the complex needs of the infant and caregivers.

Accidental Injuries

Among the safety issues that must be discussed with the infant's parents or guardians are the dangers related to aspiration and choking. The swallowing reflex matures progressively from birth, but until it is fully developed, aspiration is a risk. Also, because infants often put small objects in their mouths, choking is a risk. Choking may also result from small pieces of food, nuts, and popcorn. Parents and caregivers need instruction on what to do if the infant is choking. If the airway is obstructed and the infant is not coughing forcefully or does not have a strong cry, the parent or caregiver should give five quick back blows between the infant's shoulders while holding the infant prone over one arm. If this does not dislodge the object, the infant should be placed in a supine position over the rescuer's thighs with the infant's head supported, and five chest compressions to the lower third of the sternum should be given quickly. The cycle of five back blows, followed by five chest compressions should continue until the object is expelled or the infant becomes unresponsive. If the infant becomes unresponsive, CPR needs to be initiated (Topjian et al., 2020).

As the infant becomes more mobile, the risk for falls or for being caught in a dangling cord (such as in mini-blinds) increases. Preventive measures against such safety hazards must be taught to new parents or guardians. In addition, the law requires using special car safety seats and restraints for infants. See the accompanying display, Examples of Actual or Potential Health Problems and Needs: Infancy Through School Age.

Examples of Actual or Potential Health Problems and Needs

INFANCY THROUGH SCHOOL AGE

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Feeding ADL deficit	• Insufficient food or fluid intake • Barrier(s) to accessing fluid or water • Caregiver's insufficient knowledge about age-specific nutritional needs • Excessive fluid loss (vomiting and diarrhea)	• Change in disposition, crying, or activity • Decrease in urine output • Dry mucous membranes • Increase in heart rate • Failure to grow and meet developmental milestones
Injury risk	• Insufficient knowledge and adherence to safety standards with skates, bicycles, roller blades, and trampolines • Immunization level within community • Exposure to toxic chemical; unsafe water or food sources • Unsafe mode of transportation or inappropriate use of car seat restraints	

Source: Wolters Kluwer. (2020). *Problem-based care plans*. In Lippincott Advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

Sudden Infant Death Syndrome and Sudden Unexpected Infant Death

Sudden infant death syndrome (SIDS) refers to the sudden death of an infant younger than age 1 year when consideration of the infant's history, a postmortem examination, and investigation of the scene where the death occurred fails to reveal a cause of death.

Approximately 1,250 infants died of SIDS in 2019, making SIDS the leading cause of death in infants 1 to 12 months old (CDC, 2021e). **Sudden unexpected infant death (SUID)** is an all-encompassing term used for sudden, unexplained infant deaths where the cause of death cannot readily be identified prior to an investigation (CDC, 2021e). SUID includes SIDS, accidental deaths (suffocation or strangulation), natural deaths (infections and cardiac, neurologic, or metabolic disorders), and homicides (American SIDS Institute, 2022); SUID accounted for about 3,400 deaths in the United States in 2019 (CDC, 2021e).

Approximately 900 children younger than age 1 year die annually from unintentional suffocation (or strangulation) in bed (CDC, 2021e). Suffocation deaths can occur when infants co-sleep with adults, other children, or animals (Task Force on Sudden Infant Death Syndrome, 2016). These accidental deaths occur most commonly when infants share a bed with adults (co-sleeping) and are inadvertently wedged beneath another person, trapped in a dangerous position, such as between the bed and the wall, and suffocated by bedding or an unapproved infant sleep positioner (ISP). In an effort to improve diagnostic and reporting practices, the CDC supports the SUID case registry and Sudden Death in the Young case registry to monitor national trends, identify risk factors, and focus on interventions to prevent these infant deaths (CDC, 2021a).

The rate of infant deaths attributed to SIDS has declined significantly since the early 1990s when the *Safe to Sleep* campaign promoted placing infants on their backs to sleep rather than in the prone position. The American Academy of Pediatrics (Task Force on Sudden Infant Death Syndrome, 2016) issued updated safe sleep guidelines for infants that include the following A-level recommendations:

- Place infant on back to sleep for every sleep.
- Use a firm sleep surface.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Breastfeed.
- Place the infant on a separate sleep surface for room-sharing.
- Keep soft objects and loose bedding away from the infant's sleep area.
- Consider offering a pacifier at naptime and bedtime.
- Avoid smoke exposure, alcohol, and illicit drug use during pregnancy and after birth.
- Avoid overheating.
- Seek and obtain regular prenatal care.
- Immunize infants in accordance with AAP and CDC recommendations.
- Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS.
- Health care providers, staff in newborn nurseries and NICUs, and childcare providers should endorse and model the SIDS risk-reduction recommendations from birth.
- Media and manufacturers should follow safe sleep guidelines in their messaging and advertising.
- Continue the *Safe to Sleep* campaign, focusing on ways to reduce the risk of all sleep-related infant deaths, including SIDS, suffocation, and other unintentional deaths; pediatricians and other primary care providers should actively participate in this campaign.

Child Maltreatment

In the United States in 2020, 1 in 7 children experienced child abuse and neglect, with approximately 1,840 children dying due to abuse or neglect (CDC, 2021c). The Federal Child Abuse Prevention and Treatment Act (CAPTA), as amended and reauthorized by the CAPTA Reauthorization Act of 2010, defines child abuse and neglect as, at minimum, "Any recent act or failure to act on the part of a parent or caretaker which results in death, serious physical or emotional harm, sexual abuse or exploitation; or an act or failure to act which presents an imminent risk of serious harm" (Child Welfare Information Gateway, 2019b, p. 2). Although **child maltreatment** may occur at any age, most victims are from birth to age 4 years. Most states recognize four types of child maltreatment: physical abuse (nonaccidental physical injury), sexual abuse (visual depiction, rape, molestation, prostitution, incest, or other exploitation), emotional or psychological abuse (pattern of behavior), and neglect (failure to provide for physical, medical, educational, or emotional needs). Abandonment, parental/guardian substance use, and human trafficking are also classified as abuse or neglect in many states (Child Welfare Information Gateway, 2019b).

Childhood abuse and neglect have long-term physical, emotional or psychological, behavioral, and societal consequences for health—these traumatic experiences and the related negative effects are referred to as ***adverse childhood experiences*** (ACEs) (Child Welfare Information Gateway, 2019a). Individual outcomes vary widely and are affected by the age and developmental stage when the abuse or neglect occurred; the type of maltreatment; the frequency, duration, and severity of the maltreatment; and the relationship between the child and perpetrator. Long-term physical effects can include chronic health conditions such as cardiovascular disease, lung and bowel disease, cancer, and diabetes. Abuse or neglect can result in immediate neurologic consequences, such as brain damage from head trauma (shaking), but is also associated with long-term consequences such as reduced brain volume (size) and functional deficits in emotional regulation, learning, memory, motor function, and executive functioning (Child Welfare Information Gateway, 2019a). Additional psychological consequences of abuse or neglect can include an inability to regulate emotions, issues with executive functioning and cognitive skill development, attachment and social difficulties, mental health issues, and posttraumatic stress disorder with the associated symptoms. Unfortunately, these can lead to behavioral consequences including substance abuse, criminality, continuation of the abuse and neglect cycle, and sexual risk-taking. These consequences affect society and lead to significant direct and indirect costs (Child Welfare Information Gateway, 2019a).

Although child abuse occurs in all racial and ethnic groups and at all levels of society, certain factors increase the risk, including the following (Child Welfare Information Gateway, 2019a; Psychology Today, 2019):

- Caregivers' substance abuse; this includes manufacturing, distribution or selling, using, and prenatal exposure
- Caregivers experiencing stress from poverty or unemployment
- Caregivers' mental illness or other health problems
- History of violence in the family or community
- Physical or mental disabilities in the child or children that may increase caregiver burden
- Caregivers' lack of knowledge about parenting and the normal behaviors and development of children
- Lack of family and social support for caregivers, social isolation of families, lack of family cohesion, single caregiver, young caregivers

The fact that many cases of child abuse are not reported to police or social services is a national concern. Health care providers and facilities, teachers, daycare providers, and social workers are in an excellent position to recognize families at risk and offer interventions. In all 50 states, these professionals have a legal obligation to report suspected maltreatment (see Chapter 7). Organizations that serve as resources for child abuse concerns are listed in Table 23-2. The long-term treatment of children who are abused and their families is complex and requires input from the entire interprofessional team. Fostering the development of protective factors for victims of maltreatment at the individual, relationship, and community levels can prevent and mitigate some of the effects of abuse or neglect (Child Welfare Information Gateway, 2019a). Although children may overcome the ACEs and manage or recover from residual effects,

they benefit from prevention, early recognition, and appropriate intervention.

nurse and other health care team members are required to report Hillarie's case to begin an investigation. Although Hillarie may not be a victim of child abuse, the safety and well-being of this child is of paramount importance. All efforts will be made to treat and protect this child.

Role of the Nurse in Promoting Health and Preventing Illness

The most essential role of the nurse in promoting health of the infant is teaching family members or guardians and caregivers. Teaching ranges from providing basic information about prevention of diaper rash to facilitating grieving in parents who have lost a baby to SIDS. Examples of specific areas of preventive teaching for parents or guardians of infants are given in Teaching Tips 23-1 on page 604.

Immunization against contagious diseases begins during the first year of life and should follow a regular schedule, as outlined in Figure 23-3. Health care providers need to listen to parents' or guardians' concerns about immunization and guide them to resources with current immunization information and schedules (CDC, 2021b). Guidelines for new or evolving vaccines, such as the COVID-19 or Ebola vaccine, are based on recommendations from the Advisory Committee on Immunizations Practices (AICP) and are frequently updated (https://www.cdc.gov/vaccines/hcp/acip-recs/index.html).

Technology Alert

The Centers for Disease Control and Prevention offers a CDC Vaccines Schedules App for clinicians and other health care professionals. This application provides free online access to the latest immunization schedules, associated footnotes, and immunization resources. Download the app here: https://www.cdc.gov/vaccines/schedules/hcp/schedule-app.html#download

Teaching Tips 23-1

INFANTS

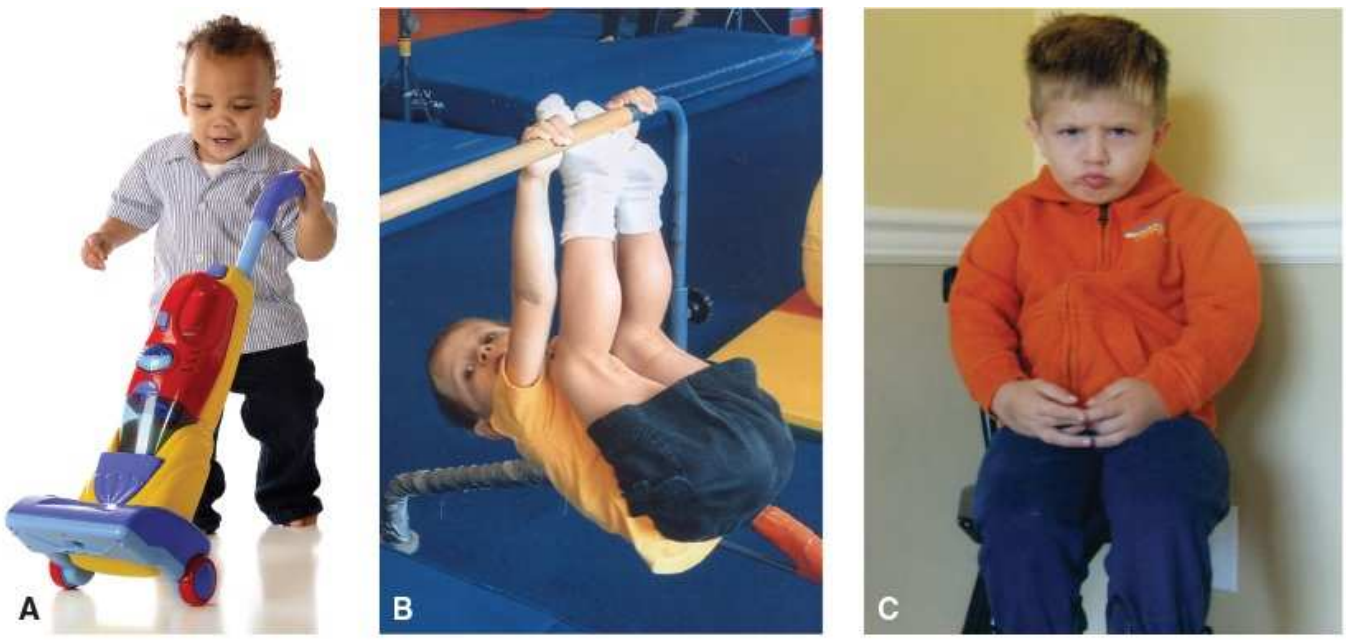
Health Topic	Teaching Tip	Why Is This Important?
Safety	• Feed the baby slowly and burp often. • Do not prop bottles and leave the baby unattended. • If choking occurs, follow appropriate procedure to give back blows and chest thrusts or CPR. • Place infants on their backs in safe cribs with no crib bumpers, loose bedding, or toys. Keep the crib rails up at all times. • Avoid co-sleeping with parents, other children, and animals. • Never leave the baby unattended in or near water. • Use approved car seat restraints. • Keep small objects out of reach. • Never leave the baby unattended on a table, chair, or regular bed. • Place the baby on their back for sleeping. • Keep plastic bags and mini-blind cords out of reach. • Block stairs with gates. • Cover electrical outlets.	The leading causes of death in infants are drowning, suffocation, and falls. Infants wiggle, roll, creep, crawl, walk, and reach for objects. Propping bottles, even in later infancy, may increase the risk of aspiration and tooth decay. Placing babies on their back to sleep has significantly reduced the incidence of SIDS.
Nutrition	• Provide breastfeeding instructions. • Provide instructions on preparing formula and information about positioning for feeding. Stress the importance of holding the baby for feeding. • Discuss the introduction of solid foods,	Feeding is a time for the caregiver and baby to strengthen attachment and bonding. There is no one best time to introduce solid foods, but they should be started one at a time. If breastfeeding, complimentary foods should not be introduced until age 6

	as prescribed by the health care provider. Instruct the parent or caregiver not to add sugar, salt, or honey to foods.	months. Overfeeding or adding extra calories may cause obesity in the infant or in later life.
Hygiene	• Teach caregiver how to bathe the baby and care for the umbilical cord. • Teach how to provide skin care for males if circumcision is chosen. • Tell caregiver to keep the diaper area clean and dry.	Skin care, as well as care for the umbilical cord and circumcision site, are necessary for preventing infections and excoriations.
Elimination	• By age 2 months, babies usually have two stools a day. • Breastfed babies vary more in bowel consistency, color, and times than babies fed formula.	Renal and intestinal physiology develop throughout the first year of life.
Growth and Development	• Provide consistent care and love. • Growth and development differ for each infant, but there are some predictable milestones. • Provide educational toys appropriate to the age of the infant. • Talk and read to the baby. • Allow the baby to explore different shapes, sizes, tastes, and experiences.	The infant must be consistently loved and cared for in order to thrive, learn to trust, and achieve developmental tasks. Stimulation with age-appropriate toys and the freedom to explore influence intellectual development.
Promoting Health and Preventing Illness	• If a danger of lead ingestion exists, take appropriate measures and have the baby screened. • Maintain schedule of immunizations. • Contact health care provider for care of respiratory infections. • Wean baby off pacifier in the second 6 months of life. • Stress importance of supplemental fluoride if water is not fluoridated. • Continue well-baby checkups as recommended. • Do not smoke in the house or car with the baby. • Keep infants younger than 6 months out of direct sunlight and covered with protective clothing and hats.	Infants who ingest lead, such as from eating peeling lead-based paint, are at risk for brain damage, behavioral problems, and mental deficiency. Immunizations are an essential part of health care. Upper respiratory infections may spread to involve the middle ear or lungs. Fluoride is necessary for tooth structure. Cigarette smoke of any type (active or passive) is dangerous and may increase the risk of respiratory illnesses, asthma, and ear infections. Infants in daycare have increased exposure to respiratory and skin infections and infestations.

It is also important to assess the infant's growth and development. Growth rate is assessed in comparison with standardized growth charts developed for males and females, whose growth rates differ. Be careful when comparing an individual child's growth to standards on a chart for the following reasons:

- Every child has individual variations and short-term spurts and lags in growth.
- Atypical infants, such as those who are premature or have low birth weight, are not accounted for in such charts.
- At around age 3 months, weight gain is generally lower for breastfed infants. World Health Organization (WHO) growth charts were normed based on infants who are breastfed; therefore, current recommendations are to use the international WHO growth charts for children ages birth to younger than 2 years, and then transition to the CDC growth reference charts ages 2 through 20 years to monitor growth (CDC, 2015).

The inexpensive Denver Developmental Screening Test (DDST II) is commonly used to quickly assess for atypical developmental patterns in infants and children. The crucial areas of development assessed in the DDST II are gross motor behavior and skills, fine motor behavior and skills, language acquisition, and personal and social interaction. The test identifies problem areas that require more precise assessments. The DDST II is described in more detail in most pediatric nursing texts.



When an infant in late infancy is hospitalized, separation anxiety behaviors are common. **Separation anxiety**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

normally occurs when a child is separated from loved ones who offer security. It usually begins at about age 6 months and continues through the preschool period. At a later age, the young child is able to predict this happening and feels anxiety even before the separation occurs. The infant may initially cry and scream in the phase of protest, but then stop crying and appear depressed, which is the despair phase (Hockenberry et al., 2022). Nurses should facilitate parents or guardians staying with the hospitalized infant; when that is not possible, consistent health care providers are important to promote the infant's trust in others.

TODDLERS: 1 TO 3 YEARS

From ages 1 to 3 years, the child is considered a **toddler** (Fig. 23-4).

Toddlers enter a stage of autonomy, promoting exploration.

The curious and independent tod - dler often has a desire to do things by himself.

Discipline helps toddlers learn inner control and understand limits.

Cognitive development can be promoted by allowing the toddler the opportunity to observe and imitate. Younger siblings particularly enjoy mimicking older siblings.

Play in toddlerhood might be solitary or parallel.

FIGURE 23-4. Development in the toddler. (Courtesy of Amy Roach.)

Physiologic Development

Physiologic development continues steadily through the toddler years, but the pace is considerably slower than in infancy. In terms of growth and development, the toddler:

- Has rapid brain growth, increase in length of long bones of the arms and legs, and growth of muscles
- Uses fingers to pick up small objects
- Walks forward and backward, runs, kicks, climbs stairs, and rides a tricycle
- Drinks from a cup and uses a spoon
- Is typically four times the birth weight at age 2 years, averaging 30 to 35 lb (13.6 to 15.9 kg) and 23 to 37 inches (58.4 to 94 cm) in height.
- Has bladder control during the day and sometimes during the night (ages 2.5 to 3 years)
- Turns pages in a book and, by age 3 years, draws stick people

Cognitive Development

Toddlers are in Piaget's (Piaget & Inhelder, 1969) last two stages of sensorimotor development: beginning to understand object permanence, following simple commands, and anticipating events. Toddlers can understand self as separate from others and have a beginning perception of body image. Toddlers can identify and name several body parts, and they have a sense of biologic sex identity. Language begins at about age 1 year, with the use of one- or two-syllable sounds. At about age 2 years, children begin to use short sentences.

Psychosocial Development

Freud's Theory

The toddler is in Freud's (1960) anal stage. Increased muscle development and sphincter control encourage the child to focus on the pleasure of sphincter contraction and relaxation. Toilet training becomes a major focus during this period.

Erikson's Theory

The toddler enters Erikson's (1963) stage of autonomy versus shame and doubt. Autonomy is developing from independence in feeding, walking, dressing, and toileting, as well as the ability to express wishes verbally. Children who do not feel autonomous may be reluctant to explore and may be fearful of activities and people.

Negativism (characteristically expressed by saying, "no") and outbursts of temper result from the toddler's efforts at control over the environment. **Regression**, demonstrating behavior that is more characteristic of a younger age, can occur at any time in response to stressful circumstances. The most common regressive behaviors are excessive clinging to caregivers, loss of control over elimination, and the use of more infantile speech patterns.

Separation anxiety in response to separation from the mother figure intensifies at about age 18 to 24 months and can be as intense for the toddler as it was for the infant. The child may have feelings of anger, fear, grief, and revenge during this period, but, by age 24 months, the toddler begins to demonstrate increased independence from the mother or other primary caregiver (Hockenberry et al., 2022).

Havighurst's Theory

The toddler has the developmental task of learning to control the elimination of urine and feces and begins to learn sex differences, form concepts, learn language, and distinguish right from wrong (Havighurst, 1972).

Health of the Toddler

Accidents—such as motor vehicle crashes, poisonings, burns, drowning, choking and aspirations, and falls—are the major cause of death in toddlers. The number of young children visiting the ED due to ingestion of small button batteries has significantly increased. These batteries, typically 20 mm in diameter, are readily accessible and used in many toys and household products including remote controls, cell phones, and cameras. Ingestion and the associated injuries occur in children younger than age 6 years 70% of the time. Most batteries pass through the body, but some can lodge in the esophagus and cause serious burn injury within 2 hours. Battery removal may be required though endoscopy (upper gastrointestinal system) or bronchoscopy (lungs). Other emergency treatment (guided by information obtained from the National Battery Ingestion Hotline) may be implemented within 12 hours of ingestion to mitigate potential complications (Jatana et al., 2017; Khalaf et al., 2020; Mubarak et al., 2021). Dental problems are also common, especially if the toddler is allowed to go to sleep while sucking on a bottle of milk or sweetened liquid. Respiratory tract and middle-ear infections are common. Some surgeries, such as repair of a cleft lip and palate, may be done in the toddler years. Autistic disorder—with abnormal behavior, social interactions, and communication—is usually diagnosed by the time the child is 3 years old.

OTC cold medications can have serious adverse effects in infants and toddlers. The U.S. Food and Drug Administration (FDA) supports product labels on OTC cough and cold medicines that state "do not use" in children under the age of 2. The FDA is also changing labels to indicate that medications containing codeine or hydrocodone should not be used by children under the age of 18 (U.S. Food & Drug Administration, 2018). In addition to the concerns about misuse of the drugs, data indicate that they have minimal therapeutic value for this age group.

Role of the Nurse in Promoting Health and Preventing Illness

The role of the nurse in promoting health in the toddler continues to be primarily teaching, as shown by the examples in Teaching Tips 23-2. An important part of teaching is helping caregivers encourage their toddler's independence while setting firm limits.

Teaching Tips 23-2

TODDLERS

Health Topic	Teaching Tip	Why Is This Important?
Safety	• Lock medicines, cleaning supplies, and yard-care products out of reach. • Use safety plugs in electrical outlets. • Block stairs with gates. • Use approved car seat. • Never leave toddler unattended near water. Have toddler wear Coast	Accidents are a leading cause of injuries and death in toddlers. It is necessary to childproof the home to prevent injury, as the toddler moves quickly, lacks judgment, and explores the world by seeing, touching, and tasting. Small objects or balloons may be aspirated

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	Guard–approved life jackets around pools. • Do not give toddler small hard foods, small toys or toy parts, or balloons. • Keep plastic bags and mini-blind cords out of reach. • Teach danger in simple terms (“stove hot”). • Do not toss toddler in the air or swing by the arms.	and cause suffocation. Joints may be dislocated by swinging the child.
Nutrition	• Do not scold for messiness while eating. • Provide finger foods. • Short periods of loss of appetite are normal. • Avoid foods that are high in fat, sugar, and salt (often found in fast foods). • Watch for signs of food allergies. Reactions to milk, egg, peanuts, tree nuts, fish, shellfish, soy, and wheat are the most common.	The toddler is growing less rapidly than the infant and does not require as many calories. Feeding self, even if messy, promotes independence. Giving too much food or food that is high in calories may result in obesity. Children with food allergies are more likely to develop asthma or other allergies.
Hygiene	• Teach hand washing after eating and toileting. • Teach how to brush teeth. • Schedule dentist visit.	It is important to establish good hygiene and to serve as a role model. The first dentist visit may be just to become familiar with the office and provider.
Elimination	• Physical development is necessary for toilet training. • Begin training with bowel elimination. • Watch for signs of readiness (realizing wetness, staying dry for 2 or more hours). • Night dryness occurs later than day dryness.	The neuromuscular control necessary for elimination occurs between ages 1 and 3 years. Bowel training is a less complex task than bladder training.
Growth and Development	• Encourage independence in eating, dressing, and toileting. • Provide toys that emphasize gross motor skills and creativity. • Parallel play with other children is normal. • The concept of sharing is not yet developed. • Saying “no” to almost everything is normal.	The toddler gains a sense of security and control by being able to eat, dress, toilet self, and say “no.”
Promoting Health and Preventing Illness	• If a danger of lead ingestion exists, take appropriate measures and have the toddler screened. • Complete immunizations. • See health care professionals for treatment of respiratory infections. • Do not smoke in the house or car with the child. • Limit sun exposure or use sun protection practices. • Learn CPR for emergencies.	Toddlers who ingest lead, such as from eating peeling lead-based paint, are at risk for brain damage, behavioral issues, and intellectual disability. Immunizations are an essential part of health care. Respiratory infections may lead to ear infections. Avoid smoking to reduce risk of respiratory illness, asthma, and ear infections. Passive smoke is dangerous. Infants in daycare have increased exposure to respiratory and skin infections and infestations. Children at high risk for development of skin cancer include those with light skin, freckling, or a family history.

Toddlers who require hospital care experience stress and separation anxiety when parents are not present. To decrease stress from unfamiliar surroundings and caregivers, nurses should facilitate parents or guardians staying with the hospitalized toddler as much as possible. Every effort should be made to have consistency of health care providers and to maintain familiar routines and rituals. When ill or in pain, toddlers often regress to earlier behaviors, such as wanting a bottle or thumb-sucking.

Recall 2-year-old **Hillarie Browning**. As Hillarie regains consciousness, the nurse should apply knowledge about the feelings of stress and separation for a hospitalized toddler when developing the care plan for this child, especially in light of possible child abuse. Consistency in staff members caring for the child and maintaining rituals would help foster trust and minimize upset.

Preschooler play is associative and cooperative in its social dimension, and cognitive development is demonstrated in constructive and pretend play.

Motor abilities include throwing and catching a ball.

Safety is a common concern for caregivers.

Preschoolers enjoy imitative play.

Cognitive development produces improved reasoning ability and readiness to read.

FIGURE 23-5. Development in the preschooler.

PRESCHOOLERS: 3 TO 6 YEARS

At around age 3 years, toddlers begin to move into the next stage: **preschooler**. Although growth and development are slower than in infancy and toddlerhood, they are still steady (Fig. 23-5).

Physiologic Development

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

The physical characteristics of the preschooler include the following:

- The head is close to adult size by age 6 years.
- The body is less chubby and becomes leaner and more coordinated.
- Motor abilities include skipping, throwing and catching a ball, copying figures, and printing letters and numbers.
- A full set of 20 deciduous teeth is present; baby teeth begin to fall out and are replaced by permanent teeth.
- Average weight at ages 5 to 6 years is 45 lb (20.4 kg), with males being slightly heavier than females.

Cognitive Development

Preschoolers are in Piaget's (Piaget & Inhelder, 1969) preoperational stage of development. Passing through the preconceptual and intuitive phases, preschoolers demonstrate the following transitional changes:

- Egocentrism decreases as socialization with other children increases, and the ability to express self verbally improves.
- Play is more related to real-life events (rather than fantasy).
- Basic curiosity results in constant questions and improved reasoning ability.

Language development is seen in more elaborate and grammatically correct sentences, with 6- to 18-word sentences becoming common by age 6 years. Incessantly asking "Why?" increases the child's knowledge, encourages further conversations, and helps develop language abilities.

Preschoolers clearly identify themselves as male or female, start to develop a sexual orientation, can understand basic body functions, and have a curiosity about biologic sex differences. This curiosity often leads to "playing doctor," which is normal behavior at this stage. Many children in this age group want to look special or *dressed up* and gain increased self-esteem from compliments about their appearance.

Psychosocial Development

Freud's Theory

The preschooler is in Freud's (1960) phalic stage, with the biologic focus primarily genital. This is frequently associated with the Oedipal and Electra complexes (See Chapter 22). This affinity for a parent has since been discussed in relation to sexual identity formation, cultural and current political influences, and the complexities inherent in self-discovery (Dabbous, 2021; Flanders et al., 2016). As a result of this development and differentiation of self, the superego and conscience begin to develop.

Erikson's Theory

The preschooler is in Erikson's (1963) stage of initiative versus guilt. Inner turmoil occurs when natural curiosity is pitted against a constant examination of the propriety of one's actions by a rigid conscience. Realistic self-limits are learned through social interactions.

Havighurst's Theory

According to Havighurst (1972), the preschooler has four developmental tasks to accomplish: to learn biologic sex differences and modesty, to describe social and physical reality through concept formation and language development, to get ready to read, and to learn to distinguish right from wrong.

Special Considerations

Preschoolers often have fears—most commonly fear of new places, fear of the dark, and fear during nightmares. These fears are often made worse by the child's own fertile imagination and ability to fantasize. Support and validation of the preschooler's feelings by caregivers are essential.

Moral and Spiritual Development

Kohlberg's preconventional phase of moral reasoning dominates at this age. The focus of this stage is obeying rules to avoid punishment or receive a reward. The cognitive, psychosocial, and moral developments of the preschooler provide a base for spiritual development, as described by Fowler (1981). The preschooler may attend activities at church or synagogue with the family but does not understand religious concepts. The concept of a deity is literal, with God usually being viewed as a male human. Concepts such as heaven, hell, and holy spirits are incomprehensible and often frightening.

Health of the Preschooler

Preschoolers continue to have the health problems that are seen in toddlerhood. Communicable diseases and respiratory tract infections are common, especially with increased interaction with other children at nursery schools and daycare. Preschoolers are prone to accidents because of their increased curiosity about the world. Some congenital disorders—such as hypospadias, inguinal hernias, and cardiac anomalies—require surgery at this time. Dental caries become common if teeth are neglected. As language becomes more sophisticated, speech disorders may become apparent.

In the United States as well as worldwide, obesity is a significant threat to the health of children. The incidence of

children with obesity has more than tripled since the 1970s. Although only one component of an obesity assessment, BMI measurement, discussed in detail in Chapter 37, is a standard used to determine obesity and correlating predictors. A national representative study of children and adolescents ages 2 to 19 years (Fryar et al., 2021) found that between 2017 and 2018, 19.3% fit into the category of obesity (body mass index [BMI] at or greater than the age- and sex-specific 95th percentile on the CDC growth charts), with 6.1% fitting into the category of extreme obesity (at or greater than 120% of the age- and sex-specific 95th percentile on the CDC growth charts). Young children (younger than 5 years old) who are overweight or obese are more likely to be obese as adolescents and adults, and have chronic health problems such as heart disease, high blood pressure, type 2 diabetes, stroke, cancer, asthma, and osteoarthritis. Racial and ethnic disparities persist, but there are also disparities rooted in income level. Based on published data, in 2019-2020, obesity rates ranged from 8.6% among youth in the highest income bracket to 23.1% among youth in the lowest income bracket (Robert Wood Johnson Foundation, 2021). Federally funded programs including the Supplemental Nutrition Assistance Program (SNAP), the Women, Infants, and Children (WIC) program, the Child and Adult Care Food Program (CACFP), and Head Start provide much needed support for families. Reimagining school-based programs became a necessity during COVID-19, when meals normally obtained at school needed to be accessed by children and families in their homes. Work is ongoing to provide support and structure for dietary requirements and physical activity recommendations (Robert Wood Johnson Foundation, 2021). (See Research in Nursing box.)

Research in Nursing

BRIDGING THE GAP TO EVIDENCE-BASED PRACTICE

Considering Childhood Obesity in Light of COVID-19

Most people are aware that obesity has become an epidemic. In the United States by 2030, nearly 50% of Americans are projected to be obese, with women, non-Hispanic Black adults, and low-income adults most commonly predicted to fall into the severe obesity category (Ward et al., 2019). Experts contend that this is a complicated situation, which was negatively impacted by the COVID-19 pandemic. Communities need to consider multifaceted ways to provide support for children to make healthy decisions beginning at an early age, even with the additional stressor of a global pandemic.

Related Research

Alves, J. M., Yunker, A. G., DeFendis, A., Xiang, A. H., & Page, K. A. (2021). BMI status and associations between affect, physical activity, and anxiety among U.S. children during COVID-19. *Pediatric Obesity*, *16*(9), e12786. https://doi.org/10.1111/ijpo.12786

The study considered 64 children ages 9 to 15 years from April 22 to July 29, 2020, the summer COVID-19 was at its height, and national (and global) shutdowns and stay-at-home measures were in full effect. The children kept logs regarding their physical activity, completed the state portion of the *State-Trait Anxiety Inventory* and the 10-item *Positive and Negative Affect Schedule for Children*. Results considered extraneous variables and are valid for the children in the study irrespective of age, sex, socioeconomic level, or maternal gestational diabetes diagnosis. Unsurprisingly, anxiety scores were over five standard deviations higher than pre-pandemic norms for children in this age range. Children classified as overweight or obese who reported more time engaged in physical activity, reported less anxiety. This supports the idea that physical activity is beneficial for children during periods of high stress. Leisure screen time, which averaged 6 hours per day, was associated with a negative effect in all children (healthy weight, overweight, and obese). A positive effect was significantly related to anxiety levels in all children. Although this study was performed at the height of the COVID-19 pandemic and highlights the potential negative implications for children with an elevated BMI at times of crisis.

Relevance to Nursing Practice

The long- and short-term effects of living through a global pandemic are still unknown. Stressors can have negative effects on the psychological and physical well-being and health of children—these effects can extend into adulthood. Considering potential ramifications of the pandemic provides the opportunity to develop mitigating strategies and inform future responses to large-scale, global issues that affect people of all ages.

Role of the Nurse in Promoting Health and Preventing Illness

Teaching Tips 23-3 provides examples of teaching to promote health in preschoolers. Nurses play a vital role in identifying children at risk for obesity, teaching families about the health consequences, providing information and health teaching, and promoting wellness in this vulnerable population. Assessments of dietary patterns and physical activity level of family members guide nursing interventions.

When caring for a preschool-aged child who is scheduled for surgery or requires hospitalization, nurses must recognize the importance of the child's fear of pain as well as separation anxiety. The nurse can help decrease fears by explaining procedures in language the child can understand and by being honest about how much pain a procedure will

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

cause. Many health care institutions and facilities have preprocedure visits so that the child having surgery becomes familiar with the setting and the activities that will be done. Allowing the child to practice procedures on a doll and encouraging the child to express their feelings openly are also beneficial (Fig. 23-6 on page 612). Encouraging caregivers to take an active role in the child's care helps to reduce fear and separation anxiety.

SCHOOL-AGED CHILDREN: 6 TO 12 YEARS

The **school-aged child**, ages 6 to 12 years, is typically sturdy and strong. Physical growth during this time is relatively slow but continues steadily, with both refinement and subtle changes taking place (Fig. 23-7 on page 612).

Physiologic Development

Physiologic development of school-aged children includes the following:

- The brain reaches 90% to 95% of adult size; by age 12 years, the nervous system is almost completely matured, resulting in coordinated body movements.
- Motor abilities progress from the ability to hold a pencil and print words at age 6 years to the ability to write in script (if cursive is taught), type complete thoughts, and compose full sentences by age 12 years.

Teaching Tips 23-3

PRESCHOOLERS

Health Topic	Teaching Tip	Why Is This Important?
Safety	• Lock medicines and cleaning and gardening supplies out of reach. • Use safety plugs in electrical outlets. • Teach child how to go up and down stairs. • Do not give small hard foods, small toys, or balloons. • Tape shut battery compartments of toys and household objects to limit access to button batteries. • Use approved car seats and bicycle helmets. • Teach simple traffic safety. • Teach to never talk to or get in the car with a stranger. Include information about inappropriate touching. • Never leave the child alone in public or unattended in a car. • Begin swimming lessons and teach water safety. • Teach danger of fire and have a home fire safety plan. • Limit use of bouncers or moonwalks and trampolines. Limit the number of children using them at one time and always have a parent present.	Accidents are the leading cause of injury and death in preschoolers, most often from motor vehicles, drowning, burns, and poisoning. Even minor head trauma may cause hematoma formation. Children are at risk for harm from physical and sexual abuse and must be taught how to recognize situations that may increase that risk. Broken bones and sprains are the most common type of bounce-related injuries; the number of children in the United States with this type of injury is 15 times higher now than 15 years ago.
Nutrition	• A gradual increase in calories, with nutritious snacks, is necessary. • Children who follow their own appetite patterns are less likely to be overweight. • Avoid foods that are high in fat, sugar, and salt (found in most fast foods). • Preschoolers like to eat one food at a time and prefer those that are mildly flavored and lukewarm.	The preschool child needs the same food group nutrition as the adult, but in smaller amounts. Lifelong eating patterns begin during this time frame, so healthy nutrition that promotes a normal BMI should be taught and modeled.
Hygiene	• Stress importance of hand washing	Preschoolers are able to carry out basic

	before meals and after toileting. • Assist with brushing and flossing teeth after eating. • Teach disposal of used tissues. • Maintain regular dental checkups and care.	hygiene but continue to need assistance and reminders. Dental caries often begins during this age.
Elimination	• Toilet training is completed, but night wetting may persist.	Recognizing the need to empty the bladder during sleep takes a longer time in some children. They should not be punished for wetting the bed.
Growth and Development	• Night fears and bad dreams are common. • Make-believe play and imaginary friends are normal. • Although each child grows and develops differently, there are ranges of normal. • Play occupies most of the child's time; the child can play with others for periods of time. • Provide play materials that encourage physical activity, dramatic play, quiet play, and creativity. • Provide consistent, fair, and kind limits for behavior. • Masturbation is normal, although the child should learn that it is not acceptable in public.	Sleep problems usually resolve on their own; calm reassurance by parents is appropriate when they occur. Play is the work of the child; adults should provide time, space, equipment, and safety, but should not structure the child's play.
Promoting Health and Preventing Illness	• If a danger of lead ingestion or poisoning exists, take appropriate measures and have the child screened. • Maintain immunizations. • Have vision tested. • Have hearing tested if necessary (e.g., child does not seem to listen). • Maintain regular well-child checkups. • Preschoolers often fear dental and medical treatments. Avoid hospitalizations when possible; if necessary, prepare the child before the procedure.	Lead poisoning in preschoolers causes brain dysfunction. Immunizations and health-related checkups are essential in promoting health. Preschoolers often see dental or medical procedures as a punishment and fear damage to their bodies. Parents should set a good example and be honest with the child. Preparation for procedures and hospitalization can help decrease fear and separation anxiety.

- Digital natives are able to interface with computer programs, learning management systems, and games with minimal instruction or supervision.
- Sexual organs grow, but are dormant until late in this period, when hormonal changes begin.
- All permanent teeth are present, except for the second and third molars, by age 12 years.
- Height increases 2 to 3 inches (5.1 to 7.6 cm) and weight increases 3 to 6 lb (1.4 to 2.7 kg) a year.

FIGURE 23-6. Abstract reasoning is necessary for children to understand that painful medical treatments given now will make them feel better later. Dramatic play may help the preschool child, who is not old enough to have developed abstract reasoning, to understand the uncomfortable experiences of the hospital stay. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

Play involves development of skill, games with rules, and competitive activities.

The school-aged child is aware of and understands a sequence of events. Making friends is important to the school-aged child.

FIGURE 23-7. Development in the school-aged child. (*Source:* A. Used with permission from Shutterstock. *Photo by Dmytro Zinkevych*. C. Used with permission from Shutterstock. *Photo by Una Shimpraga*.)

Cognitive Development

The school-aged child is in Piaget's (Piaget & Inhelder, 1969) concrete operational stage of development, organizing facts about the environment to use for problem solving. In this period, the child has the following characteristics:

- Thinks logically and develops concepts of mass, volume, weight, and measurement
- Deals best with actual objects and people, but can relate concepts and compare events
- Uses inductive reasoning to solve new problems
- Generalizes about people, places, and things
- Develops classification systems

- Develops an awareness and understanding of other people's feelings and points of view
- Understands reversal of events

School-aged children have well-developed language skills and use language in a more sophisticated manner. Their ability to store information in long-term memory and retrieve it in the remembering (recall) process is more efficient. Texting and other social media platforms require knowledge of shorthand and social norms that begin to be understood and assimilated within this time frame.

Psychosocial Development

Freud's Theory

The school-aged child is in the latency stage, according to Freud (1960), with psychosocial energies being channeled toward strong identification with their own biologic sex and biologic sex–oriented creative activities. Privacy and understanding of their own body are important at this age.

Erikson's Theory

The school-aged child is in the industry-versus-inferiority stage, according to Erikson (1963), with the child focused on learning useful skills and thereby developing positive self-esteem. A sense of identity begins to emerge, and values are integrated. The emphasis is on doing, succeeding, and accomplishing.

Think back to **Nate Pelton**, the 11-year-old baseball player. The nurse could apply Erikson's theory to understand that joining a sports team offers Nate the opportunity to develop physical skills, to learn to play as a member of a team, and to improve self-esteem. When children participate in sports, their parents/guardians or caregivers need to be actively involved to ensure safety while understanding that support and positive reinforcement help to promote a positive experience that will shape values and behaviors for adult life.

Havighurst's Theory

According to Havighurst (1972), the school-aged child has the following developmental tasks:

- Learning physical game skills
- Learning appropriate social roles
- Developing fundamental skills in reading, writing, and calculating
- Developing concepts necessary for everyday living
- Achieving personal independence
- Developing conscience, morality, and a scale of values

Special Considerations

Peer relationships become the major influence. They shape the child's view of their status or popularity, preferred or desirable skills and activities, and ability to be liked and accepted in diverse peer groups. Peer groups in middle childhood help prepare the child for getting along in the larger world. They help the child practice role-transition behaviors that will be needed when the child transitions from looking to the parent or guardian for guidance, to adult independence. Sexual orientation, gender identification, and sexual activity discussions among the peer group often begin at this stage. Unfortunately, as children become members of social groups, they may experience some form of bullying. Data indicate that bullying behavior becomes more common at school during unstructured moments such as recess and may be related to biologic sex or gender identity, physical appearance, disability or ability, and intellect. Bullying behavior intends to embarrass or harm the victim and creates a perceived imbalance of power between the aggressor (or aggressors) and the victim (Hockenberry et al., 2022).

Body image, self-concept, and sexuality are interrelated. Sexual development results in a strong need to understand body function and to have accurate information about sexuality.

Moral Development

Most of middle childhood is spent in the conventional phase of moral development. Behavior is based on familial and peer group beliefs, and conformity to the norm is common. Following school regulations, respecting teachers, and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

viewing justice as a means of fair play are all important.

Spiritual Development

In Fowler's (1981) theory, school-aged children view religious faith as a relationship that involves reciprocal fairness. They take part in rituals of their faith, with a basic understanding of the ritual's significance. The importance of spiritual beliefs and the possibility of life after death is accepted, even if not totally understood.

Health of the School-Aged Child

Accidents continue to be common in school-aged children. With increased interactions with other children in school, communicable conditions such as scabies, impetigo, and head lice are more prevalent. The CDC recommends vaccination with a two-dose series of the human papillomavirus (HPV) vaccine before age 15 years, with the first dose recommended at ages 11 or 12 years (can be given starting at age 9), to prevent the types of HPV that can cause cervical cancer and genital warts (CDC, 2021b). (See the accompanying PICOT in Practice display on page 614.)

Other common health-related problems of the school-aged child include obesity, attention-deficit hyperactivity disorder (ADHD), learning disability (LD), and enuresis (bed-wetting). In addition, chronic conditions such as sickle cell anemia, hyperactivity, seizure disorders, hypertension, type 1 diabetes mellitus, and obesity may affect the school-aged child. Scoliosis, an abnormal curvature of the spine, occurs most often in females between ages 10 and 13 years.

PICOT in Practice

ASKING CLINICAL QUESTIONS

Scenario: You are a nurse who works in a primary care clinic. A 13-year-old adolescent is being seen for a wellness visit prior to starting a new school year. You review the patient's electronic health record (EHR) and note that she has not had the human papillomavirus (HPV) vaccine. The patient says that no one told her that she needed the HPV vaccine.

You know that the adherence rates in your clinic are low for initiation and completion of the HPV series compared to national averages (CDC[a] estimates 66% initiation and 51% completion rates among adolescents in the United States). You wonder if automated calls and reminders for health care providers to offer the vaccine would increase the initiation and completion of the two-dose schedule for the HPV vaccine for females by age 19 years.

- **Population:** Adolescent females and males ages 11 to 19 years
- **Intervention:** Participation in centralized reminder and recall from state immunization information systems to increase HPV vaccination rates
- **Comparison:** No use of cues for health care providers
- **Outcome:** Initiation and completion of HPV vaccine
- **Time:** By age 19 years

PICOT Question: Among adolescents 11 to 19 years old, does the participation in centralized, automated calls and reminders from the state immunization information systems increase the initiation and completion rates of the two-dose HPV vaccine?

Findings:

Szilagyi, P., Albertin, C., Gurfinkel, D., Beaty, B., Zhou, X., Vangala, S., Rice, J., Campbell, J. D., Whittington, M. D., Valderrama, R., Breck, A., Roth, H., Meldrum, M., Tseng, C. H., Rand, C., Humiston, S. G., Schaffer, S., Kempe, A. (2020). Effect of state immunization information system centralized reminder and recall on hpv vaccination rates. *Pediatrics, 145*(5), e20192689. https://doi.org/10.1542/peds.2019–2689.

Szilagyi et al. (2020) conducted a four-arm pragmatic (effectiveness) randomized controlled trial across two states (New York and Colorado) between February 2017 and January 2019. The study focused on the impact of 1, 2, or 3 autodialer phone reminders per dose of the HPV vaccine sent to parents on behalf of the immunization information systems (IIS) and primary care practices about HPV vaccination. Practices where children received care (i.e., pediatrics, family medicine, and health center) were randomly selected. Within each practice, patients ages 11 to 17.9 years old who had not completed their HPV vaccine series (NY: n = 30,616 in 123 practices; CO: n = 31,502 in 80 practices) were randomly assigned to receive 0, 1, 2, or 3 autodialer messages per vaccine dose. The primary study outcome was initiation and/or completion of the HPV two- or three-dose vaccine series among adolescents ages 11 to younger than 19 years.

Although centralized reminder and recall by phone (autodialer) has been shown to improve childhood vaccination rates, immunization information systems–based centralized reminder and recall for the HPV vaccine did not raise HPV vaccination rates. In New York, HPV vaccine initiation rates ranged from 37.0% to 37.4%, and completion rates were between 29.1% and 30.1%, with no significant differences across study arms. In Colorado, HPV vaccine initiation rates ranged from 31.2% to 33.5% and were slightly higher for one reminder compared with none, but vaccine completion rates, ranging from 27.0% to 27.8%, were similar.

Level of Evidence: Randomized controlled trial

Recommendations: Studies have revealed that a strong provider recommendation is important in uptake of the HPV vaccine. You present a Plan-Do-Study-Act proposal to the interprofessional team responsible for clinic management. The goal of your project is to improve HPV vaccination rates using a multifaceted approach. Your proposal includes:

1. Adding a prompt in the clinic EHR to cue health care providers to discuss the HPV vaccine at all clinic visits with adolescents between ages 11 and 19 years and their parents.
2. Providing each health care provider and staff with the Centers for Disease Control and Prevention's *5 Ways to Boost Your HPV Vaccination Rates*.[b]
3. Adding a personalized patient reminder and recall system to notify patients who have completed the first dose to return to the clinic for the second dose of the vaccination at 5 to 6 months post the first dose.

Obesity

A sedentary lifestyle contributes to obesity in children who spend many hours using electronic devices, playing video games, and watching TV rather than actively playing. Many obese school-aged children also have diets that are high in saturated fats, do not meet fruit and vegetable daily requirements, and are low in fiber and calcium. As with adults, obesity in children results from consuming more calories than are expended. Genetics, health factors, and other social determinants of health may be contributing factors. (See Research in Nursing box on page 610.)

Specific Learning Disorders/Disabilities and Related Disorders

Learning disorders are conditions that affect how a person learns to read, write, speak, and perform calculations. Although the term *learning disability* is more commonly used in the legal and education systems, *specific learning disorder* is the medical term used in the DSM-5; *learning difference* may be informally used, but a medical diagnosis of a specific learning disorder often directly leads to recognition of a disability and the associated accommodations and specific school-based services (American Psychiatric Association [APA], 2021). Learning disorders tend to be discovered in school-aged children when they have difficulties in the classroom. Although many learning disorders persist over the course of a lifetime, educational support can provide essential tools and strategies that help to mitigate the challenges of a learning disorder. Three of the most common learning disabilities include the following (APA, 2021; National Institutes of Health [NIH], 2018):

- *Dyslexia:* difficulty in language skills, reading, and spelling
- *Dysgraphia:* writing disability; difficulty putting thoughts on paper
- *Dyscalculia:* difficulty with numbers and arithmetic (symbols)

Disorders associated with learning disabilities include dyspraxia (sensory integration disorder involving motor coordination) and attention-deficit/hyperactivity disorder (ADHD). ADHD is the most common chronic neurodevelopmental condition in U.S. children. It affects 8.4% of U.S. children (more than five million children) ages 2 through 17 years (Chang et al., 2020). Parents or guardians tend to seek intervention when they note behavioral, social, or academic performance issues rooted in a pattern of inattention and/or hyperactivity and impulsivity. A thorough history and physical, coupled with the use of valid and reliable instruments assist the health care provider in ruling out other conditions and diagnosing ADHD. Early diagnosis and intervention focus on symptom reduction, improved cognitive and social function, diagnosis and management of common comorbid conditions, and the mitigation of potential long-term effects of ADHD (Chang et al., 2020). Although interventions need to be individualized for each child, psychosocial interventions that include parent/guardian training and classroom interventions focused on behavior management are the standard of care. These psychosocial interventions are a first-line treatment for preschoolers and should continue as an adjunct therapy for children ages 6 to 17 years. Providing opportunities for regular exercise and promoting adequate sleep have been shown to have a positive effect on children with ADHD. Stimulant medications (methylphenidate, dexmethylphenidate/amphetamine, dextroamphetamine) provide effective treatment and are often prescribed first line for elementary school-aged children and adolescents (Chang et al., 2020).

Guidelines from the American Academy of Pediatrics (Wolraich et al., 2019) that were reaffirmed in 2019 outline the role of the health care provider in assisting children with special education needs. These recommendations include identifying children in need of early intervention or special education services; sharing information sharing with early intervention specialists, school personnel, or clinics, and involving parents or guardians in team meetings; identifying barriers to care; addressing school involvement in documented health care treatment plans; and working with school administrators to address the needs of children with disabilities/disorders at a system level.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Enuresis

Enuresis is diagnosed when a child is at least 5 years old and is still having involuntary urination, usually at night. Although this problem is significant to the child and their parents, it is a benign and self-limiting disorder, usually ending between ages 6 and 8 years.

Recall 11-year-old **Nate Pelton**, who suffered a possible concussion during a baseball game as a result of a blow to his head in a collision with another teammate. Nurses working in the ED, schools, and public health settings should use the nursing process to provide education about the recognition and treatment of concussions and to collaborate with parents, young athletes, coaches, and school faculty to prevent and treat these injuries.

Role of the Nurse in Promoting Health and Preventing Illness

The nurse's role in promoting health for the school-aged child involves individual and family teaching, often conducted by school nurses. Multiple strategies can be implemented in schools to address the obesity epidemic, promote mental focus, and support general well-being. Recommended approaches include increasing opportunities for students to become involved in informal and formal physical activities and ensuring that students have access to affordable or free healthy food and beverage choices while at school.

Because school violence has become more common, school nurses must be prepared for a potential crisis. They need to be alert for warning signs of bullying and other dangerous behaviors and be involved in efforts to promote a safe environment in playgrounds, buses, and schools. This often includes collaboration between the school nurse, parents, and educators to determine creative strategies that promote healthier lifestyles and environments for school-aged children. The Teaching Tips 23-4 display (on page 616) provides examples of nursing activities specific for this age group. In addition, nurses often function as advocates for vulnerable populations (see the Nursing Advocacy in Action display on page 617).

QSEN BULLYING

Staying alert for bullying includes paying attention to social media, where cyberbullying is increasingly common. Cyberbullying can also occur through text, instant messaging apps, e-mail, or gaming platforms. Providing education and a method for reporting opens the door to conversation and debriefing on this important topic.

Teaching Tips 23-4

SCHOOL-AGED CHILDREN

Health Topic	Teaching Tip	Why Is This Important?
Safety	• Teach and require pedestrian traffic safety. • Wear seat belts and bicycle helmets. • Emphasize bicycle, scooter, skate, and skateboard safety. • Provide swimming lessons and water safety rules. • Rural children should be taught farm safety. • Teach how to "stop, drop, and roll" to extinguish clothing fire. • Teach the dangers of dangerous products and chemicals.	Accidents are the leading cause of death in school-aged children, most often caused by motor vehicle crashes, fires, falls, drowning, and poisonings. Gun injuries to the child firing the gun or to others occur in school-aged children. Accident prevention and safety education should be taught and reinforced both at home and at school. Concussions that are not treated properly increase the risk for long-term problems.

	• Keep guns locked up. Teach gun safety rules. • Teach use of proper equipment for contact sports. • Be alert for concussion sports injuries, use proper equipment, and follow treatment recommendations for concussions.	
Nutrition	• School-aged children need adequate calories and may also require increased amounts of vitamin D and calcium. • Provide foods that meet nutritional needs and do not supply empty calories (as found in junk food and fast food). • Make mealtimes a positive, predictable, regular event.	Increased vitamin D and calcium are needed as bones enlarge and for females to prevent later osteoporosis. American children eat too much salt, sugar, and fats; nearly 25% of all school-aged children have an elevated cholesterol level. Eating patterns for school-aged children will improve over time. Both undernutrition and overnutrition are seen in this age group.
Hygiene	• Teach females how to wipe from front to back after urination. • Teach children not to share hats or combs.	Females are prone to urinary infections because of their short urethra. Head lice and ringworm are common in school-aged children and are easily spread to others.
Sexual Development	• Both females and males have characteristics of sexual maturity, including a growth spurt, growth of body hair, changes in body proportion, and the beginning of secondary physical sex changes. • Provide accurate information and answer questions honestly about sex, including anatomy, physiology, birth control, and STIs (including HIV). • Monitor TV watching and computer use.	Females have breast development, grow axillary and pubic hair, and may begin to menstruate. Males have testicular growth and grow axillary and pubic hair, and the penis enlarges. Males may also have temporary breast enlargement. School-aged children are curious, and if unsupervised, may watch pornographic content on television or online. Consider the level of violence they are exposed to in television shows or video games.
Growth and Development	• Best friends and groups of peer friends are important to the school-aged child. • Rules are rigidly followed during games with peers. • Encourage both quiet and active play activities. • Provide guidance and set limits for behavior, focusing on only one incident at a time. • Encourage feelings of industry by having realistic expectations and recognizing unique abilities and talents. • Provide positive statements demonstrating that the child is valued, loved, and important.	From ages 7 to 9 years, close friends are usually the same biologic sex and age. This is not as important from ages 10 to 12 years. Unrealistic expectations or excessive discipline may result in stress and feelings of inferiority.
Promoting Health and Preventing Illness	• Maintain records of immunizations, and have boosters as recommended. • Promote regular physical activity and exercise. • Script with children how to say no to smoking, alcohol, and drugs in common situations.	Maintaining immunizations is essential to health; records are required for enrollment in school. Children need to know how to handle peer pressure to smoke, drink, and take drugs. Many school-aged children are at risk for and exhibit symptoms of chronic illnesses.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Maintain dental examinations.
- Maintain well-child checkups, and have screenings (if at risk or indicated by symptoms) and treatment for chronic conditions such as asthma, diabetes mellitus, sickle cell anemia, hypertension, seizure disorder, hyperactivity, and obesity.
- Have vision tested if school problems with reading, coordination, or inability to see the screen or monitor in front of the room occur.

Nursing Advocacy in Action

Patient Scenario

You are working as a school nurse in a district where there are many poor families who have come to the United States (many illegally) to find work. At present, there is a lively debate in the country about whether these families should be identified and sent "home" or supported where they currently live in the United States. Many of the parents are afraid of being deported, and you learn that some have taken their children out of school. You know that the children benefit from being in school. In addition to the education, the free school lunch program is, for many children, the one meal of the day they can count on.

Implications for Nursing Advocacy

How will you respond if you are the school nurse approached by teachers who want to help the children? Talk with your classmates and experienced nurses about these questions:

- If you elect to advocate for these children, what practical steps can you take to ensure better health outcomes?
- What is it reasonable to expect of a student nurse, a graduate nurse, and an experienced nurse in this situation?
- What advocacy skills are needed to effectively respond to this challenge?
- What are the potential risks to being a moral agent in this situation? Professional, sociopolitical, or legal considerations?

Because school-aged children are striving for independence and control, hospitalization may mean a loss of freedom of choice (e.g., types of food, clothing, activities). Children of this age should be allowed to have some measure of control over allowable activities and should be encouraged to do what they can, such as playing competitive games and making their own beds (Fig. 23-8).

FIGURE 23-8. Allowing school-aged children to play competitive games promotes a positive hospital experience. (*Source:* Used with permission from Shutterstock. *Photo by Joe Mitchell.*)

ADOLESCENTS AND YOUNG ADULTS

The adolescent and young adult years are a time of both change and stability. **Adolescence** begins with puberty and extends from about age 12 to about age 18 years; the **young adult** period is considered to be ages 18 through 39 years. However, these time periods are highly individualized, and reflect a critical window of development and occasions for nursing intervention.

After experiencing rapid growth and development during adolescence, the young adult completes physical growth and develops internal and external controls and values acceptable to society. There are no specific measurements of maturity; each person is an individual and a wide range of normal values and behaviors are considered healthy (Fig. 23-9 on page 618). The world in which young adults live has changed dramatically, with globalization and a networked world contributing to increased knowledge and information availability, heightened risks due to unhealthy and risky behaviors, relatively low social mobility, and greater economic inequality than seen in previous generations (Institute of Medicine [IOM] & National Research Council [NRC], 2015).

Physiologic Development

Changes in the adolescent's body transform the adolescent from a child to an adult in appearance. Physiologic development includes the following:

- The feet, hands, and long bones grow rapidly, accompanied by an increase in muscle mass, especially in males.
- Primary and secondary sexual development occurs, with maturation of the genitalia; presence of body hair; breast development and menstruation in females; and facial hair growth, voice changes, and spermatogenesis in males.
- Sebaceous and axillary sweat glands become active.
- Full adult size is reached, although some young males may continue to grow in their 20s.

Puberty—the time when the ability to reproduce begins—starts at age 9 to 13 years in females (with menstruation usually beginning between ages 10 and 14 years) and at ages 11 to 14 years in males. Puberty can be divided into the following three stages (Table 23-3 on page 618):

- *Prepubescence:* Secondary sex characteristics begin to develop, but the reproductive organs do not yet function.
- *Pubescence:* Secondary sex characteristics continue to develop, and ova and sperm begin to be produced by the reproductive organs.
- *Postpubescence:* Reproductive functioning and the development of secondary sex characteristics reach adult maturity.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Peer relationships are particularly influential during adolescence.

Babysitting offers an opportunity to practice formal adult skills.

The development of self-identity in adolescence involves discovering talents and becoming emotionally independent.

A primary developmental task of adolescence is to achieve new and more mature relationships.

FIGURE 23-9. Development in the adolescent. (*Source:* B. Used with permission from Shutterstock. *Photo by Joe Mitchell*. C. Used with permission from Shutterstock. *Photo by Syda Productions*. D. Used with permission from Shutterstock. *Photo by allensima*.)

Table 23-3 Adolescent Sexual Development

STAGE	MALES	FEMALES
Prepubescence	• Progressive enlargement of testicles, seminal ducts, prostate gland • Enlargement and reddening of the scrotal sac • Increase in length and circumference of penis • Appearance of downy pubic hair	• Progressive enlargement of the ovaries • Ripening of Graafian follicles • Rounding of the hips • Appearance of breast buds • Enlargement of the fallopian tubes, vagina, and uterus • Appearance of downy pubic hair
Pubescence	• Increase in amount, pigmentation, and curling of pubic hair • Growth spurt involving height and weight increase • Deepening of the voice due to growth of larynx • Enlargement of testicles • Increased pigmentation and growth of scrotum • Growth of penis in length and circumference	• Increase in amount, pigmentation, and curling of pubic hair • Growth spurt involving height and weight increase • Menarche • Appearance of axillary hair • Enlargement of vulva and clitoris • Development of breast tissue • Ovulation

	• Beginning of spermatogenesis	
Postpubescence	• Completion of sexual growth and development • Fertility	• Completion of sexual growth and development • Fertility

Cognitive Development

According to Piaget (Piaget & Inhelder, 1969), adolescence is the stage when the cognitive development of formal operations takes place. Deductive, reflective, and hypothetical reasoning are possible, and abstract concepts can be understood. Long-term goals can be set as the concept of time, its passage, and the future become real. Challenging the decision making of adults is common. Egocentrism returns, and imaginary audiences and daydreaming are common.

Young adults, in comparison to the adolescent, are more creative in thought, are objective and realistic, and are less self-centered. Their learning is enhanced through educational and life experiences.

Psychosocial Development

Freud's Theory

The adolescent and young adults are in Freud's (1960) genital stage. The libido re-emerges in a mature, adult form, and the person is capable of full sexual function. There is a sense of self and others. Creativity and pleasure are found in love and in work.

Erikson's Theory

According to Erikson's (1963) theory, the adolescent tries out different roles, personal choices, and beliefs in the stage called identity versus role confusion. Self-concept is being stabilized, with the peer group acting as the greatest influence.

The young adult, in the intimacy-versus-isolation stage, needs to complete tasks such as achieving independence from parents, establishing intimate relationships, and choosing an occupation or career. If such developmental tasks are not accomplished, the young adult may become isolated and self-absorbed.

Think back to **Darlene Schneider,** the 14-year-old pregnant teenager. The nurse could apply knowledge of Erikson's theory to foster a sense of identity in Darlene by engaging her in essential self-care measures and providing her necessary information to facilitate decision making. In addition, establishing a trusting relationship with Darlene, and subsequently between her and other members of the health care staff, would help to further promote her self-exploration and identity formation.

Havighurst's Theory

According to Havighurst (1972), during adolescence, more mature relationships with peers is achieved, a gender-influenced social role is developed, personal appearance is accepted, and a set of values and ethical system as a guide to behavior are internalized.

Levinson's Theory

In Levinson's theory of individual life structure, the years from ages 18 to 22 are characterized by early adult transition (Levinson et al., 1978). This is a time of making initial career choices, establishing personal relationships, and selecting personal values and lifestyles. During the years from ages 22 to 28, the young adult builds on previous choices, but there may be a transient quality to occupational choices and friendships.

Gould's Theory

Gould's (1978) theory of transformation views young adults as having established their own control as adults separate from the family. They want to enjoy the present but also build for the future.

Special Considerations

CHOOSING AN OCCUPATION OR CAREER

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

A major psychosocial developmental requirement for the young adult is choosing a vocation. The young person's decision to enter the world of work is strongly influenced initially by the need to become independent of their family and to be self-sufficient. The choice of an occupation or a career is also guided by factors such as the desire to get married, raise a family, and become part of the community (Fig. 23-10 on page 620).

Occupational and career choices are largely tied to educational choices. Many careers require a college education. Adults learn from both informal and formal experiences and are largely goal-directed learners. If the person's identified goals are to increase career opportunities, maintain financial stability, and pursue upward mobility, the adult will be motivated to learn and change. The major factor in achieving satisfaction with a vocational choice is a person's belief that they are functioning to capacity and contributing to society.

ESTABLISHING A FAMILY

As discussed in Chapter 4, there are many different types and configurations of families. For many people, family is not determined by blood relation—families are chosen. Nurses have to keep in mind that the concept of *family* holds different meaning for different people—sometimes this is as simple as asking a patient to identify their *family*, *folks*, or *people*. Families provide a safe zone and a buffer between the needs of people and the expectations of society. Each family has the potential to provide a caring, supportive environment. For some couples, having children requires assistive reproductive technology, surrogacy, or adoption—these can be necessary but cost-prohibitive options. Although the process for establishing a family may vary, the entire family unit tends to be involved with the addition of a new family member.

Pregnancy is a period of adjustment requiring family members to be flexible enough to adapt to the changes that pregnancy and a new family member will bring. The cognitive, psychosocial, cultural, and educational dimensions of the prospective parents influence completion of the tasks. The verification of pregnancy may raise conflicting emotions in the pregnant person and partner, influenced by such factors as whether the pregnancy was planned or unplanned and how the baby may affect career goals. As physiologic changes occur and fetal movement is felt, the pregnant person begins to visualize themselves as a mother/parent and typically assumes responsibility for the health of the growing fetus. As the time for delivery becomes closer, there is a focus on maternal/parental tasks (such as preparing the baby's room and having clothing ready) and preparing for labor and delivery. During the pregnancy, the expectant partner needs to learn the normal physiologic and psychological changes of pregnancy, accept their supportive role in meeting the birthing person's needs, and explore their feelings about the developing fetus and the birth of the baby.

Graduating college or trade school is an important developmental milestone.

Choosing an occupation and starting a career are also important developmental milestones.

Developmental tasks of the young adult center on establishing intimate relationships, a home, and a family.

FIGURE 23-10. Development in the young adult. (A. Courtesy of K. Bartlett. C. Used with permission from Shutterstock. *Photo by Monkey Business Images*.)

Moral Development

The child enters adolescence with a law-and-order orientation and may never progress beyond that point. Young adults who have mastered previous levels of moral development reach the conventional level and are concerned with maintaining expectations. They also value conformity, loyalty, and social order. Some people may enter the postconventional stage, in which they make moral judgments on the basis of universal beliefs.

Spiritual Development

Adolescents and young adults can think in the abstract and may question beliefs and practices that no longer serve to stabilize their identity or purpose. The individuating-reflective period in the young adult (defined by Fowler, 1981) brings discovery of the meaning of values as they relate to the achievement of social purposes and the acceptance of the value systems of others. Often, adolescents or young adults temporarily abandon traditional religious practices.

Health of the Adolescent and Young Adult

Although adolescence and young adulthood are times of maximum physiologic development and health, a wide variety of health problems can occur. Health promotion focuses on nutrition, relationships with self and others, and safety. The Advisory Committee on Immunization Practices now recommends routine vaccination with a quadrivalent meningococcal conjugate for children ages 11 to 12 years, with a booster of a serogroup B meningococcal vaccine provided at age 16 years (up to age 23 years, but preferably before age 18 years) when the risk for contracting meningococcal disease is highest (CDC, 2019). College freshmen living in dormitories and young adults living in military barracks are at risk for meningococcal disease and require the vaccine for protection from it. Young adults who received the Tdap vaccine at ages 11 to 12 years should have a tetanus and diphtheria (Td) booster every 10 years. Since 2000, there has been a recurrence of pertussis (whooping cough). Tdap vaccine may be given as one of these boosters if the Tdap was not previously received (CDC, 2020a). The CDC also recommends the vaccination of females ages 15 years and older who did not receive the two-dose series of the HPV vaccine when they were younger. The HPV vaccine for those ages 15 years and older is a three-dose series that prevents the types of HPV that most commonly cause cervical cancer and genital warts (CDC, 2021b). See the accompanying box, Examples of Actual or Potential Health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Problems and Needs: Adolescence, for health issues in adolescents.

Injuries

Injuries are the leading cause of death for adolescents and young adults. Motor vehicle crashes are the most common cause of mortality, often associated with the use of alcohol or other drugs. In 2019, a total of 2,375 teenagers ages 13 to 19 years died in a motor vehicle accident. Drivers ages 16 to 19 years are three times more likely to be involved in a fatal crash than drivers ages 20 years and older (Insurance Institute for Highway Safety Highway Loss Data Institute, 2021). Sports- and recreation-related injuries remain an issue for the active teenager and young adult. Basketball and general exercise were reported as the most common activities that led to injury in those ages 15 to 24 years (Sheu et al., 2016).

Suicide (Self-harm)

Since 2016, suicide has been the second leading cause of death in teenagers (ages 14–18 years). A national study of high-schoolers identified that in 2019, approximately 1 in 5 (18.8%) considered attempting suicide, 1 in 6 made a suicide plan (15.7%), and 1 in 11 attempted suicide (8.9%)—this represents an increase between 2009 and 2019. The highest prevalence of suicidal ideation and behaviors was reported by females; White, non-Hispanic teens; those who had sexual contact with the same or both sexes; and those who identify as lesbian, gay, or bisexual. However, Black, non-Hispanic teens, both male and female, had the highest prevalence estimates for suicide attempts (Ivey-Stephenson et al., 2020). Comprehensive interventions, programs, and policies are needed to address suicide risk factors such as ACEs, stigma, access to lethal suicide means, media sensationalizing deaths, and a lack of individual/familial coping skills or community support. Recognition and effective intervention with evidence-based treatment (such as cognitive behavior therapy) requires formal and informal parental, school, and community training to increase awareness and provide opportunities for implementing suicide prevention strategies (Ivey-Stephenson et al., 2020).

Examples of Actual or Potential Health Problems and Needs

ADOLESCENCE

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Risky health behavior	• Insufficient resources (knowledge, finances, role models) • Insufficient social support • Social anxiety; difficulty forming peer relationships • Peer pressure	• Poor decision making • Engagement in unsafe behaviors • Smoking, vaping • Substance use, misuse, abuse
Disturbed Personal Identity	• Alteration in actual/perceived social role • Cultural incongruence • Sexual orientation or gender identity exploration or confirmation • Discrimination, prejudice, bias, disparities • Dysfunctional family processes • Low self-esteem	• Verbalizations regarding confusion, anger, frustration • Suicidal ideation or behaviors
Readiness for Positive Family Process	—	• Demonstrated engagement with family in social situations • Verbalized desire to seek formal therapy • Open conversations that focus on family roles and responsibilities

Substance Use, Misuse, and Abuse

Smoking and the use of illegal drugs pose serious health risks, and the use of alcohol is significantly related to risk-taking behavior for adolescents and young adults. According to the annual 2020 survey of 8th-, 10th-, and 12th-graders (Johnston et al., 2021; National Institute on Drug Abuse, 2021), most illicit drug use (including LSD, MDMA, cocaine, crack, heroin, oxycontin, amphetamines, and ketamine) has not changed since the last survey. OTC cough and cold medicines, most of which contain dextromethorphan, increased for all three grades. Although vaping *just flavoring*

decreased, vaping *nicotine* and *marijuana* increased in 10th and 12th graders. Daily marijuana use, which is at or near the all-time high since 1991, may be impacted by social and legal changes occurring across the United States, as disapproval decreases and availability increases. Alcohol remains the most widely used substance by teenagers. The decline in alcohol use tracked from the 1980s through 2019 did not continue in 2020; there were significant increases in lifetime, annual 30-day, and daily alcohol use in all three groups. Young people tend to be moving away from narcotic misuse, which bodes well for the opioid crisis, but new substances and delivery devices, popularity driven by the internet and social media, and the rediscovery of older drugs all impact on the trends of substance use. Although general prevention strategies are helpful with younger children, drug-specific education and warnings tend to be more effective with this age group (Johnston et al., 2021; National Institute on Drug Abuse, 2021). Substance use disorder, including use of tobacco and alcohol, is further discussed in Chapter 28.

Pregnancy

Despite a 72% decline in the teen pregnancy rate in the United States since 1991, the U.S. teen pregnancy rate is substantially higher than in other western, industrialized countries (CDC, 2021d; Cox, 2020). The interplay among teen pregnancy, race and ethnicity, geographical location, community structures and support, and social determinants of health, particularly socioeconomic level, needs to be considered when interpreting teen pregnancy statistics. For example, when considering only age and socioeconomic status, White teens have a higher pregnancy rate than their Black counterparts, but there are no differences between the birth rates of Black and White teens (Dumas et al., 2020). Developing measures for funding, running, and promoting community-level interventions to mitigate risk need to consider socioeconomic factors (Cox, 2020; Dumas et al., 2020). Nurses should evaluate their own bias, consider their role in reducing stigma, support the unique needs of teen parents, and promote the teens' growth and development as parents and families (SmithBattle, 2020).

Nutritional Problems

Fad dieting and habitually eating fast foods are common among adolescents and young adults. Although eating disorders often surface during the teen years or young adulthood, they may also develop during childhood or later in life (National Institute of Mental Health, 2018). The most common eating disorders are anorexia nervosa (compulsive dieting to the point of self-starvation), bulimia nervosa (a destructive cycle of binge eating followed by self-induced vomiting in an effort to prevent weight gain), and binge eating disorder (excessive eating that is not followed by purging, excessive exercise, or fasting). The psychodynamics of these conditions are complex, but almost always involve a negative self-concept. Eating disorders may also be associated with anxiety or depression (National Institute of Mental Health, 2018).

Adolescents and young adults are consuming energy drinks with increasing frequency. These drinks have high levels of caffeine, which is not always clearly disclosed on the label, and are advertised to boost energy and improve mental and physical performance. Approximately 27% of students surveyed in the *Monitoring for the Future* 2010 to 2016 surveys (8th and 10th grades) reported consuming energy drinks or shots (Jackson & Leal, 2018). Because it is a stimulant, excessive caffeine levels can result in anxiety, rapid pulse, abnormal cardiac rhythms, and nervousness.

Sexually Transmitted Infections

Adolescents and young adults who engage in sexual intercourse without a condom are at a higher risk for contracting **sexually transmitted infections (STIs)** than adults. Although adolescents and young adults ages 15 to 24 years account for 50% of the 20 million new STIs in the United States, they represent only 25% of the sexually experienced population (Committee on Improving the Health, Safety, and Well-Being of Young Adults, 2015). Lack of knowledge, lack of psychosocial maturity, embarrassment, and a lack of planning ahead (e.g., not using condoms) are the most common reasons for this increased risk. Trichomonal and monilial infections, as well as HPV, are common.

Chlamydia, an infection of the genital tract, is the most common STI in the United States. Women younger than age 25 years and older women with key risk factors require screening every year (CDC, 2021f). Chlamydial infections occur in both biologic sexes, as do syphilis and herpes simplex type II (genital herpes). These STIs pose serious health threats.

Human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) is the STI that poses the greatest single threat to people and society as a whole. Although HIV can be transmitted through means other than sexual contact, transmission is primarily through genital, oral, or anal sexual activities. HIV/AIDS is a major cause of death in the world, and its incidence is predicted to further increase still further. (See Chapter 43 for an in-depth discussion of STIs.)

Developmental and Situational Stressors

Adolescents and young adults deal with many stressors related to lifestyle, occupation, and relationships.

STRESSORS RELATED TO SEXUAL ORIENTATION

Peer pressure and fear of being different can be a source of stress for a young person who is questioning their gender identity or sexual orientation. Are they physically and emotionally attracted to a person of the same or opposite sex, or to both sexes? This attraction is an evolving process, but typically emerges between middle childhood and early adolescence. New research indicates that sexual orientation may be related to genetic, hormonal, developmental, social,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

or cultural influences, but irrespective of definitive evidence, there is agreement that a person has little or no choice regarding it. There is also consensus that sexual orientation cannot be changed by medication or therapy.

Terms commonly used to describe sexual orientation include *heterosexual* (attracted to members of the opposite sex), *gay* (attracted to members of the same sex; more commonly men who are attracted to men), *lesbian* (women who are attracted to women), and *bisexual* (attracted to both sexes). When a person's internal feelings of being male or female differ from their physical anatomy, the term *transgender* is used to describe that person's gender identity. The term *questioning* describes a person unsure of sexual orientation. The acronym LGBTQIA+ is commonly used in the United States to refer to all these alternatives collectively; however, there is a growing appreciation for the fact that sex, sexual assignment, gender identity, and sexual orientation occur on a spectrum and are not fixed for some people (see Chapter 43). For an excellent teaching and learning tool, check out the Genderbread Person at https://www.genderbread.org/resource/genderbread-person-v4-0.

People who identify as gay, lesbian, bisexual, and/or transgender may experience prejudice and discrimination that can have negative psychological outcomes. Some adolescents may be reluctant to reveal their sexual orientation or gender identity for fear of ridicule, rejection, or harassment from family and friends; others may receive unconditional support and love from both groups.

FAMILY STRESSORS

Family-centered stressors include both positive and negative factors, such as marriage, divorce, parenthood, and death of a parent. Stress may precipitate mental or physical health problems that are aggravated by ineffective coping mechanisms such as substance abuse, child abuse, spousal abuse, decreased nutrition and rest, and risk-taking behavior.

Consider **Darlene Schneider**, the 14-year-old pregnant adolescent described in the case file at the beginning of the chapter. Analysis of this patient's assessment reveals multiple developmental and situational stressors affecting Darlene that place her and her fetus at high risk for problems. Using this information, the nurse could develop a highly individualized care plan that focuses on these stressors (e.g., her lack of adequate supports, multiple sexual partners, poor nutritional habits), ultimately to the benefit of Darlene and her baby.

An increasing number of people are remaining single, either by choice or situation. Singlehood status has advantages and disadvantages. Being single gives people the freedom to come and go as they choose, to have more autonomy, to pursue or create their own career vision, and to spend money and time as they wish. On the other hand, external pressures to marry and the desire for love, to belong, and to raise a family may make young adults question the decision to remain single. Single-parent households are increasingly common, with individuals raising their children with or without the presence or support (financial or otherwise) of the other biologic parent. The stressors inherent in maintaining a household and raising children exist for these families, but their support systems are often different from those identified for the traditional nuclear family (two parents with one or more children). It is important to recognize that the definition of a *nuclear household*, one that contains a single-family nucleus (center), has evolved and specifically encompasses a married-couple family with or without children, a father with children, and a mother with children (United Nations Statistics Division, 2021).

Couples may encounter difficulties conceiving, delay childbearing until their careers are established, or choose not to have children. If they want to have children, infertility (defined as the inability to conceive after 1 year of coitus without contraception) may add even more stress. Women who have postponed having children may realize in their middle to late 30s that their so-called biologic clock is winding down; an increasing number of women in this age group are having their first child.

Divorce and separation are common in our society, with rates being highest among those marrying or cohabitating at a young age, having low income, and having low educational levels. It separates children from their families, has long-term emotional costs, and increases the number of single-parent families headed by women.

One-person, nuclear, composite/multi-person (friend or partner included), and extended households exist and thrive in the United States. Although for census and documentation purposes the term *family* refers to blood relatives (United Nations Statistics Division, 2021), informally, family has come to mean whomever the patient identifies as family. Recognizing and activating these resources and important people in their lives can make a difference in developing robust support systems for our patients.

Role of the Nurse in Promoting Health and Preventing Illness

A true assessment of adolescent development must include the profound changes in reproductive functioning. Beyond that consideration, perhaps one of the more significant nursing activities for people in this stage is facilitating healthy family relationships. Mutual respect, open communication, and accurate information exchange among family members pave the road for a healthy transition from adolescence to adulthood.

In this age group, acute illness is often more of an annoyance than a serious issue. If hospitalized, an adolescent's and young adult's motivation to recover and to resume normal activities is strong. Because independence and self-sufficiency are important to adolescents and young adults, they will not easily accept the dependent sick role. Although chronic illnesses are less common, their occurrence can lead to delayed development, loss of independence, and permanent changes in personal and career goals. Prolonged hospitalization, long-term care, or home care increases the adolescent's feelings of isolation and may disrupt normal development. Educational and recreational activities should be provided, if at all possible (Fig. 23-11).

Teaching Tips 23-5

ADOLESCENTS AND YOUNG ADULTS

Health Topic	Teaching Tip	Why Is This Important?
Safety	• Encourage drivers' education classes for adolescents, if available. • Discuss the relationship of alcohol and drug consumption to motor vehicle crashes. • Provide information about water safety, gun safety, and sports safety.	Most deaths in people between ages 15 and 24 years are the result of motor vehicle crashes, homicide, and suicide.
Nutrition	• Encourage a diet based on the food groups, with added calories during the adolescent growth spurt. • Refer for counseling for extremes in either underweight or overweight. • Discuss nutritional problems that may result from too much fast food and too many soft drinks. • A balance of food intake, exercise, and rest is important.	Nutritional needs increase to meet the accelerated physical growth and development during adolescence. Being underweight may result from an inadequate intake of calories, or in extreme cases from anorexia nervosa or bulimia. An intake of calories in excess of metabolic needs can lead to being overweight.
Sexual Development	• Secondary sex characteristics are fully developed. • Both males and females are physically capable of reproduction. • Discuss sexual behavior, biologic sex, and gender identification openly and honestly with adolescents.	The development of secondary sex characteristics that began in the school-aged child is completed during adolescence. Sexual behavior in adolescents and young adults may result in disease or pregnancy, as well as decreased self-esteem.
Growth and Development	• The adolescent is primarily influenced by the peer group. • Risk-taking behavior, especially in males, is common. • Maintaining open communication with teens is important. • Encourage increasing independence in the adolescent and young adult but continue to provide love and support. • Assist with clarifying values and goals for future occupation.	Peer groups may have positive or negative effects. The rapid physical and emotional changes of adolescence require revising self-concept and body image. These should stabilize by late adolescence. The young adult is usually living independently and has an occupation of choice.
Promoting Health and Preventing Illness	• Have immunizations and boosters as recommended. • Have regular physical, vision, and dental examinations. • Always have a physical examination	Immunizations and regular health-related examinations are essential to maintaining health. Chronic illnesses such as hypertension, cardiovascular disease, and diabetes mellitus may

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

before participating in sports activities.
- Know your breasts and testicles and report any changes.
- Learn to say “no” to pressures to have sexual activity.
- Engage in safer-sex practices if sexually active.
- Have an annual Pap test and pelvic examination if sexually active.
- Know the dangers of STIs (from genital, oral, and anal sex) and have HIV testing especially if sex without a condom is practiced.

appear during adolescence and young adulthood. Sexual desires are high, and sexual activity is common. STIs are a major health problem, with more than two-thirds of those infected younger than 25. Untreated STIs may result in sterility in females and males or infection of an unborn fetus.

FIGURE 23-11. Adolescents with chronic illnesses can avoid feelings of isolation by using social networking sites to communicate with their peers.

Unfolding Patient Stories: Christopher Parrish • Part 1

Christopher Parrish, age 18, is hospitalized for management of cystic fibrosis with weakness and weight loss. What areas of health promotion should the nurse discuss with Christopher? How can the nurse help an adolescent with a chronic illness avoid feelings of isolation? (Christopher Parrish’s story continues in Chapter 32.)

Care for Christopher and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients’ care in DocuCare (thepoint.lww.com/DocuCareEHR).

Teaching activities to promote health for adolescents and young adults are listed in Teaching Tips 23-5.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Based on the information presented in Chapters 22 and 23, describe nursing interventions to meet developmental needs for the following patients:

- An infant hospitalized for treatment of a serious birth defect involving the heart and lungs
- A toddler with a fracture of the left leg, treated in the emergency department and then sent home
- A school-aged child, now in rehabilitation, with burns on both arms

- A 20-year-old hospitalized for injuries resulting from an automobile accident after drinking alcohol

. During your home visit to a 16-year-old girl with cancer, she says, "I don't believe in God." What would you reply? Why would you respond this way?

. During a clinic visit, a 2-month-old infant appears listless and constantly cries. The mother tells you that he has colic, so she has been diluting his formula with water. What would you do now?

PRACTICING FOR NCLEX

. The nurse assesses an Apgar score of 4 for a newborn. What action will the nurse take next?

a. No intervention is necessary: this is a normal score.
b. Provide respiratory assistance.
c. Perform CPR.
d. Wait 5 minutes and repeat the scoring process.

. A school nurse is educating parents of school-aged children about safety issues at a parent–teacher meeting. What topics are appropriate for the nurse to include for this age group? Select all that apply.

a. Childproofing the home
b. Choosing a car seat
c. Teaching pedestrian traffic safety
d. Providing swimming lessons and water safety rules
e. Discussing alcohol and drug consumption related to motor vehicle safety
f. Teaching the child how to "stop, drop, and roll"

. Nurses on a pediatric unit encourage parents of hospitalized infants and toddlers to remain with their children to help decrease what potential problem?

a. Attachment
b. Separation anxiety
c. Risk for injury
d. Failure to thrive

. A nurse is teaching parents of toddlers how to spend quality time with their children. Which activity is developmentally appropriate for this age group?

a. Playing video games
b. Playing peek-a-boo
c. Playing in a sand box
d. Playing board games

. A mother tells the nurse that she is worried about her 4-year-old daughter because she is "overly attached to her father and won't listen to anything I tell her to do." What information will the nurse convey to this parent?

a. This is normal behavior for a preschooler.
b. She and her family should see a counselor.
c. Try to spend more time with her daughter.
d. Her child should be tested for autism.

. A school nurse is counseling parents of teenagers who are beginning high school. Which issues would be priority topics of discussion for this age group? Select all that apply.

a. Influence of peer groups
b. Bullying
c. Water safety
d. Eating disorders
e. Risk-taking behavior
f. Immunizations

. A nurse working with adolescents in a group home discusses the developmental tasks appropriate for adolescents with the staff. What is an example of a primary developmental task of the adolescent?

a. Working hard to succeed in school
b. Achieving independence from parents
c. Developing athletic activities and skills
d. Accepting the decisions of parents

. A school nurse at an elementary school is lobbying the school board to provide more fruits and vegetables on lunch

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

menus and for snacks. Which rationale does the nurse give the board for this request?

a. Children who are overweight tend to grow up and have chronic health problems.
b. Children do not get sufficient vitamins, minerals, and proteins.
c. The school exists in the center of a food desert.
d. Children who are overweight are more prone to bullying.

. A nurse is teaching new mothers about infant care and safety. What will the nurse include as a teaching point?

a. Keep infants younger than 6 months out of direct sunlight.
b. Use honey instead of sugar in homemade baby food.
c. Place the baby on their stomach for sleeping.
d. Keep crib rails down at all times.

. The school nurse at a high school with a day care center identifies which of these individuals as at highest risk for abuse?

a. 6-month-old baby who cries vigorously when their parent leaves
b. Teen whose parents are divorcing
c. Student with an STI displaying risky sexual behaviors
d. Adolescent who sprained their ankle at soccer practice

. The school nurse is speaking to the parent of a school-aged child who is returning to school after the death of the other parent. The nurse explains that which of these behaviors most likely indicates regression due to great stress on the child?

a. Bedwetting when previously toilet trained
b. Wanting to play video games
c. Crying loudly when sad
d. Being afraid of the dark

ANSWERS WITH RATIONALES

. **b.** A newborn who scores 4 to 6 on the Apgar chart typically requires respiratory or special assistance. Normal Apgar scores are 7 to 10. Those who score below 4 are in need of life-saving measures.

. **c, d, f.** Important safety topics for school-aged children include pedestrian traffic safety, water safety, and fire safety. Childproofing a home would be appropriate for parents of a toddler, choosing a car seat would be an appropriate topic for parents of an infant or toddler, and teaching drug and alcohol as it relates to motor vehicle safety would be a more appropriate topic for parents of adolescents.

. **b.** Separation anxiety is a normal response when a young child (age 6 months through preschool) is separated from loved ones who offer security. This presents with initial crying followed by a despair phase during which the child no longer cries and appears depressed. Encouraging parents or guardians to remain with hospitalized children decreases this anxiety and promotes the child's trust in others.

. **c.** Playing in a sand box with toys that emphasize gross motor skills and creativity is a developmentally appropriate activity for a toddler. Video games may be appropriate for school-aged children and adolescents but should be monitored. Playing peek-a-boo is developmentally appropriate for an infant, and playing board games usually begins with preschool and older children.

. **a.** Preschoolers, according to Freud, are in the phallic stage, with the biologic focus primarily genital. The child has a sexual desire for the opposite-sex parent, but as means of defense strongly identifies with the same-sex parent. This is normal behavior for a preschooler; the family does not need counseling or autism testing. Spending more time with the child is always a good idea but is not the solution for normal behavior.

. **a, b, d, e.** Appropriate topics of discussion for parents of adolescents include peer groups, bullying, eating disorders, and risk-taking behaviors. Discussing immunizations would be appropriate for parents of children from infants to school-age. Water safety should be taught in the preschool and school-age years.

. **b.** Adolescence is a time to establish more mature relationships with both males and females of the same age.

. **a.** Overweight school-aged children often become overweight adolescents and adults who are at risk for heart disease, high blood pressure, type 2 diabetes, stroke, cancer, asthma, and osteoarthritis. Primary prevention of obesity in children has far-reaching, long-term benefits. While it may be true that some children can have nutritional deficiencies, a school may be located in a food desert, and that overweight children are more prone to bullying, the overarching goal is primary prevention.

. **a.** Infants younger than age 6 months should be kept out of direct sunlight and covered with protective clothing and hats. The nurse should also teach parents *not* to add honey or sugar to homemade baby food, to place the baby on the *back* for sleeping to prevent SIDS, and to keep the crib rails *up* at all times.

. **c.** Psychological consequences of abuse or neglect can include behavioral manifestations including substance abuse, criminality, continuation of the abuse and neglect cycle, and sexual risk-taking. The other behaviors described are not specific for abuse.

. **a.** Regression is manifested by behavior that is more characteristic of a younger age and can occur at any time in response to stressful circumstances. The most common regressive behaviors are excessive clinging to caregivers, loss of control over elimination, and the use of more infantile speech patterns.

Middle and Older Adulthood

Ethel Peabody

Ethel, an 88-year-old single woman, is being discharged from the hospital. She shows signs of early dementia, and was treated for cardiac problems this hospitalization. She has no family and lives in a small, two-story house with her three cats. There is some concern about her safety at home. She depends on a neighbor for help and refuses to consider moving to a retirement community or extended-care facility.

Larry Jenkins

Larry, a 67-year-old man with diabetes, states, “Everything’s gone downhill since I retired 5 months ago.” He reports being “bored out of my mind” and drinking more alcohol simply because “there’s nothing else to do!”

Rosemary Mason

Rosemary, a 49-year-old woman who comes to the clinic with her 54-year-old husband, confides that

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

she wishes drugs that treat erectile dysfunction had never been discovered. “I was happier when we just cuddled at night. Now he wants to try all sorts of things, and I just don’t have time or energy for this!”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Summarize the theories that describe how and why aging occurs.
. Describe major physiologic, cognitive, psychosocial, moral, and spiritual developments and tasks of middle and older adulthood.
. Describe common health problems in middle and older adulthood.
. Discuss physiologic and functional changes that occur with aging.
. Describe common myths and stereotypes that perpetuate ageism.
. Describe nursing interventions to promote health for individuals in middle and older adulthood.
. Identify the health care needs of older adults in terms of chronic illnesses, accidental injuries, and acute care needs.

Nursing Concepts

Advocacy
Cognition
Development
Family
Identity
Sexuality

Key Terms

ageism
Alzheimer’s disease (AD)
cascade iatrogenesis
delirium
dementia
elder abuse
functional health
gerontologic nursing
gerontology
gerotranscendence
life review
middle adulthood
older adult
polypharmacy
reminiscence
sarcopenia
social isolation
structural racism
sundowning syndrome

Aging is a gradual process, characterized by continued development and maturation. The changes of aging begin as one enters middle adulthood. The onset and effects of those changes throughout the middle and older adult years are influenced by numerous biological, psychosocial, and environmental factors. The physiologic changes of aging, first experienced in middle adulthood, become more obvious in older adulthood. Continued cognitive and psychosocial development throughout adult life depends to a great extent on a person’s sense of self-concept and prior ability to adapt.

This chapter continues the discussion of growth and development from previous chapters, focusing on the aging years. For an example addressing the older adult, see the Reflective Practice box.

BIOLOGICAL THEORIES OF AGING

Although there are valid sociologic, psychological, and nursing theories of aging that will be embedded in our discussion of aging, this chapter will begin with the biological theories of aging. As a person ages, changes in cells, tissues, organs, and organ systems occur. Scientists do not fully understand why some people, even within the same family or environment, age much more rapidly than others. Although internal processes may influence aging, other factors, such as nutrition and the environment, also play a role. Numerous theories describe how and why aging occurs, but none is universally accepted. These nonstochastic (predetermined) and stochastic (by chance) biological theories of aging focus on a variety of factors, including genetic inheritance, cell metabolism and function, and the immune system (Eliopoulos, 2022; Miller, 2019).

Genetic Theory

The genetic theories of aging hold that lifespan depends to a great extent on genetic factors. In one theory, genes within the organism control *genetic or biological clocks*, which determine the occurrence and rate of metabolic processes, including cell division. This telomere–telomerase hypothesis is based on the understanding that a finite number of cell divisions are possible, so cellular death is essentially preprogrammed.

Neuroendocrine and Immunity Theories

Two other preprogrammed theories involve the neuroendocrine and immune systems. The neuroendocrine system contains the pituitary and hypothalamus that serve as control mechanisms for the entire body. As age advances, these control mechanisms fail, which leads to failure of the body's essential pacemaker, and death.

The immunity theory of aging focuses on the functions of the immune system. This system—composed primarily of the bone marrow, thymus, spleen, and lymph nodes—seeks out and destroys foreign agents (such as viruses, bacteria, and perhaps cells undergoing neoplastic changes). The immune response declines steadily after younger adulthood as the thymus loses size and function. Age-associated changes in the immune system, also known as *immunosenescence,* are thought to be responsible for the increase in infections such as pneumonia and septicemia, immune disorders, and cancer as adults age. There is also some evidence to support an increase in autoimmune disorders, with the body essentially attacking itself. Some authorities believe that nutrition plays an important role in maintaining the immune response; therefore, there is much interest in vitamin supplements (such as vitamin E) that are believed by some to improve immune function.

Stochastic Theories

Stochastic theories of aging are based on the idea that there is a randomness to cellular damage and errors that makes predicting aging and death impossible. One example is the *wear and tear theory* in which organisms wear out from increased metabolic functioning, and cells become exhausted from the constant energy depletion that occurs when the body continually adapts to stressors. The organism eventually wears out from use.

Cross-linkage, a chemical reaction that produces damage to the DNA and cell death, forms the basis for another theory. As a person ages, cross-links accumulate, leading to essential molecules in the cell binding together and interfering with normal cell function. This manifests as a decrease in elasticity and flexibility.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

Mrs. Ethel Peabody is an 88-year-old single woman who is being discharged from the hospital. She shows signs of early dementia, and was treated for cardiac problems this hospitalization. She has no family and lives in a small, two-story house with her three cats. When the provider ordered her discharge, I had grave concerns about her ability to live safely on her own. When I asked if she had ever thought about moving to a long-term care facility or retirement community, she said, "I'd rather die than go to one of those places!" When I directly expressed that I was worried about her safety, she told me her cats would take care of her. When I repeated this conversation to the charge nurse, the charge nurse said, "There is nothing we can do if the patient isn't willing to explore other options."

Thinking Outside the Box: Possible Courses of Action

- Feel satisfied that I had reported my concerns to the charge nurse and let whatever happens happen.
- Explore hospital and other resources to determine realistic options for someone like Mrs. Peabody;

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

consider the obligations of caregivers and the hospital.
- Find my instructor and seek their counsel.
- Seek out the unit's social worker, outline my concerns, and see if they have other recommendations.

Evaluating a Good Outcome: How Do I Define Success?

- Both Mrs. Peabody's safety and autonomy are protected.
- I feel at peace with the decision that was made for the patient and the role I played in this decision.
- My personal and professional integrity are intact.
- My legal responsibilities and those of the institution are met.

Personal Learning: Here's to the Future!

Sadly, I must confess that I was invited to accompany another patient for a diagnostic study off the unit, so I never followed through on my concerns. Mrs. Peabody was discharged to her home, and I never learned what happened to her. However, I was troubled by my inaction and discussed this situation with my instructor. As a result, I am now aware of more available options that I can use when faced with similar situations in the future. The number of older adults will continue to grow, presenting many similar challenges in the future. I want to make sure I'm prepared for my next "Mrs. Peabody." Meanwhile, I will be talking with our patient-relations person, the social worker, hospital risk manager, and our office on aging to increase my knowledge of support services for older adults.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? Can you think of other ways to respond? What could the nursing student have done differently? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety when caring for patients like Mrs. Peabody?

Patient-Centered Care: How might the student have interacted with the charge nurse, social worker, and other pertinent hospital personnel to promote a safe, structured home environment for Mrs. Peabody while respecting her preferences? What alternatives are available to allow this patient to remain in her home while ensuring her safety? If available options to assist Mrs. Peabody had been explored during her hospitalization, what nursing actions might be helpful as this information is shared with the patient?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to develop to facilitate your role as a patient advocate? What skills would be of particular importance when dealing with the charge nurse? What strategies might be appropriate to ensure that you function as a valued member of the health care team?

Safety/Evidence-Based Practice: How might the lack of any home care interventions affect the outcome for Mrs. Peabody? What safety measures could be enacted that would allow Mrs. Peabody the opportunity to request assistance when needed? What evidence in nursing literature provides guidance for decision making regarding patients living alone with impaired cognition?

Informatics: Can you identify essential information that must be documented in Mrs. Peabody's electronic record regarding her cardiac condition and treatment? Why is it important to document an assessment of the patient's current mental health status? Can you identify any other essential information that supports safe patient care and that should be included in the electronic record? Does the unit or hospital have a program where patients are called for follow-up? Will Mrs. Peabody follow up with her primary care provider? What documentation would be useful for these teams?

The *free radical* theory is based on oxidative stress. Free radicals, formed during cellular metabolism, are molecules with unpaired, high-energy electrons that seek to combine with another molecule. This inappropriate electron pairing disrupts cell membranes and affects DNA and protein synthesis. Over time, irreversible damage results from the accumulated effects. Antioxidants are thought to protect against this type of free radical damage.

MIDDLE ADULTHOOD

The **middle adulthood** years are generally considered to be ages 40 to 65 years. This is a period of gradual, individualized changes in both physical and psychosocial dimensions. Because the average lifespan has increased, most

people in this age range still consider themselves young compared with the older adult population. Visible signs of aging and a heightened awareness of the time left to live lead adults in middle adulthood to evaluate their achievement of goals, and influence their adaptation to older age.

Physiologic Development

In the early years of this period of life, physical functions are usually still effective. As time passes, gradual internal and external physiologic changes occur. These are not pathologic changes, but normal changes that result from aging. The person must modify self-image and self-concept to successfully adapt and accept these normal changes. Physical changes of the adult in middle adulthood are outlined in Box 24-1.

The hormonal changes that take place in midlife affect males and females differently. Females undergo menopause, a gradual decrease in ovarian function, with subsequent depletion of estrogen and progesterone. This change usually occurs between 40 and 55 years of age. With the cessation of ovulation, menstrual periods stop either gradually or abruptly, causing many females to experience hot flashes, mood swings, and fatigue. The loss of estrogen also increases the risk for osteoporosis and heart disease. The process can last for several years; afterward, the female can no longer become pregnant. Males do not experience physical symptoms from the decreased levels of hormones, called andropause. Androgen levels diminish slowly; males may have some loss of sexual potency, but are still capable of reproduction.

Box 24-1 Physical Changes in the Middle Adult Years

- Fatty tissue is redistributed; males tend to develop abdominal fat, females thicken through the middle.
- The skin is drier.
- Wrinkle lines appear on the face.
- Gray hair appears, and males may lose hair on the head.
- Cardiac output begins to decrease.
- Muscle mass, strength, and agility gradually decrease.
- There is a loss of calcium from bones, especially in perimenopausal females.
- Fatigue increases.
- Visual acuity diminishes, especially for near vision (presbyopia).
- Hearing acuity diminishes, especially for high-pitched sounds (presbycusis).
- Hormone production decreases, resulting in menopause or andropause.

Remember **Rosemary Mason**, the 49-year-old woman described at the beginning of the chapter. The nurse could incorporate information about the differences in hormonal changes for males and females into a teaching plan to help Rosemary understand and adjust to the changes that are occurring.

Cognitive Development

Cognitive and intellectual abilities of middle-aged adults change little from young adulthood. There often is increased motivation to learn, especially if the knowledge gained can be applied immediately and has personal relevance. Problem-solving abilities remain consistent throughout adulthood, although response time may be slightly longer. This is not due to a decrease in ability, but may be related to having more memories to process or a desire to think a problem through before responding.

Psychosocial Development

The middle-aged adult years often are a time of increased personal freedom, economic stability, and deepening social relationships (Fig. 24-1). This is also a time of increased responsibility and an awareness of one's own mortality. The middle-aged adult realizes that their life may be half (or more) over and may feel many things are still undone. This realization can lead to a developmental crisis and situational stressors. Several theories regarding the developmental tasks of middle adulthood are described below.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Erikson's Theory

According to Erikson (1963), the middle-aged adult is in a period of generativity versus stagnation. The tasks are to establish and guide the next generation, accept middle-age changes, adjust to the needs of aging parents or other important people, and reevaluate goals and accomplishments. Adults who do not achieve these tasks tend to focus on themselves, becoming overly concerned with their own physical and emotional health needs.

Havighurst's Theory

The developmental tasks of the individual in middle adulthood described by Havighurst (1972) are learned behaviors arising from maturation, personal motives and values, and civic responsibility. To successfully master this developmental stage, the middle-aged adult must accept and adjust to physical changes, maintain a satisfactory occupation, assist children to become responsible adults, adjust to aging parents, and relate to their spouse or partner as a person.

FIGURE 24-1. The middle adult years are generally characterized by expanded social relationships, renewed relationships with a spouse or partner, and expanded family roles. (*Source:* Top left: *Photo by Monkey Business Images/Shutterstock.*)

Levinson's Theory

Levinson (Levinson et al., 1978) theorized that the individual in middle adulthood may choose either to continue an established lifestyle or to reorganize their life in a period of midlife transition.

Gould's Theory

Gould (1978) viewed ages 35 to 43 years as a time when adults look inward. He considered ages 43 to 50 years as a time when adults accept their lifespan as having definite boundaries, and have a special interest in their spouse or partner, friends, and community. He viewed ages 50 to 60 years as the period when adults experience increased feelings of self-satisfaction, value the spouse or partner as a companion, and become more concerned with health.

Adjusting to the Changes of Middle Adulthood

Various changes can take place during the middle years. These include changes in employment, relationships with a spouse or partner, relationships with children who are becoming adults, and relationships with aging parents or other important people. Midlife transition may occur in people of all genders in their 40s. Although an individual may not feel that they are aging, the realization that others consider them "old" or "older" can be stressful.

Employment

Middle-aged adults may experience changes in employment. They may opt for a career change and return to school to obtain new knowledge and skills. These changes often result from a need for increased job satisfaction, satisfying a lifelong goal, or economic conditions. Some employees in this age group have lost their jobs because of company downsizing during the recent economic turmoil and have had to acquire new skills and additional education to find employment in other areas. Individuals who have been immersed in a career may decide to have children and either become stay-at-home parents or reduce their workload. Increasing numbers of middle-aged adults are self-employed, often working from home.

As the 50s approach, questions about retirement and economic security become more prevalent, with an increased interest in the benefits of financial and retirement plans. These concerns can be heightened by overall economic conditions. For example, many people who had planned on an early retirement may decide to continue their active employment status, whereas others who had planned to work longer are laid off and forced into an unplanned early retirement. The security of retirement investments and income is critical to ensure that people remain financially stable and that workers receive the pensions they are working toward or have already achieved.

Spousal Relationships

Relationships with a spouse or a partner may change. Although for many this is a time of greater security and stability with stronger emotional commitment and sharing, for some it is a time of disenchantment. Either partner may develop negative or critical feelings and attitudes as a result of changes in physical appearance, energy levels, or sexual needs and abilities. Dissatisfaction with not achieving career or family goals contributes to the stresses placed on the marriage. Extramarital affairs and divorce may result.

Recall **Rosemary Mason**, the 49-year-old woman, voicing displeasure with her husband's desire to "try all sorts of things" sexually. The nurse could use this information about spousal relationships to gather additional assessment data about the couple's relationship before her husband started medication to treat his erectile dysfunction. This would help develop an appropriate care plan that addresses Rosemary's current displeasure.

Loss of a spouse or a partner is more likely in middle adulthood. The loss is a major crisis and a threat to a person's self-concept, and may result in a major role change. Many changes may occur, including a reduced income, changes in lifestyle and social relationships, and the need for help to work through the loss and grief (see Chapter 44).

Relationships With Children and Aging Family Members

Middle-aged adults may be caught in a *generation sandwich*. Their children may be independent and married, with children of their own, or may be recent college graduates who have returned home to live. Difficulty finding employment coupled with the burden of student loans often necessitates the postponement of independent living. Providing ongoing support for adult children while simultaneously caring for aging family presents a unique set of financial, logistical, resource, and emotional stressors for middle-aged adults.

Although much has been written about the *empty-nest syndrome* that occurs when the last child leaves home, most middle-aged parents welcome the increased space, time, and independence they have when active parenting ceases. However, as their involvement with and responsibility for children decrease, middle-aged adults may be called upon to help care for aging parents and other family members. The physical aging or death of a parent makes the middle-aged adult's own aging and inevitable death a reality.

Moral Development

According to Kohlberg (1969), a middle-aged adult may either remain at the conventional level or move to the postconventional level of moral development. The person who has had sustained responsibility for the welfare of others and has consistently applied ethical principles developed in adolescence is more likely to move to the postconventional level. At this level, the adult believes that the rights of others take precedence, and takes steps to support those rights.

Spiritual Development

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

As with moral development, not all adults progress to Fowler's (1981) conjunctive or paradoxical–consolidative state of spiritual development. Fowler believed that only some people reach this stage, and only after age 30 years. Many people in middle adulthood who reach this stage are less rigid in their beliefs, recognize paradoxes in life, appreciate symbolism, engage in mutual perspective-taking that considers norms and implicit bias, and consider a new sense of justice.

Health of the Middle-Aged Adult

Middle-aged adults are subject to physical and emotional health problems associated with lifestyle behaviors, developmental or situational crises, family history, and the environment. Both acute and chronic illnesses are more likely to occur, and recovery takes longer. This is a result of slower and more prolonged responses to stressors, more pronounced reactions to an illness, and the possibility of more than one illness being present at a time.

The leading causes of death in the middle adult years (ages 45 to 64 years), according to 2019 statistics, are malignant neoplasms; cardiovascular/heart disease; unintentional injury, including poisoning, motor vehicle accidents, and falls; suicide; chronic lower respiratory disease; liver disease; diabetes mellitus; cerebrovascular causes; nephritis (kidney disease); and septicemia (infection; Centers for Disease Control and Prevention [CDC], 2021d). Other major health problems include rheumatoid arthritis, obesity, alcoholism, and depression.

The risk for these common health problems often depends on a combination of lifestyle factors and aging. As individuals get older, energy requirements decrease. Middle-aged adults tend to maintain previous eating patterns and caloric intake while being less physically active. This trend can result in obesity and atherosclerosis, with an increased risk for high blood pressure, coronary artery disease, renal failure, and diabetes. Additionally, smoking and alcohol consumption put the person at greater risk for cancer, chronic respiratory diseases, and liver disease.

Chronic illness in middle-aged adults has a major effect on self-concept and may precipitate changes in life structure. For example, after a serious heart attack, a person may face changes in family role, earning capacity, and social relationships. Such changes usually cause great stress.

Middle age does not automatically result in physical or emotional health problems. Many people remain healthy throughout their lives, but knowing preventive health care practices and their special needs at this age can help middle-aged adults have improved quality and quantity of life. In fact, many adults cultivate new eating and exercise habits when they personally experience the metabolic and functional changes associated with aging.

Role of the Nurse in Promoting Health and Preventing Illness

The nurse has a major role in promoting health and preventing illness in middle-aged adults by teaching, serving as a role model, and encouraging self-care responsibilities. See the accompanying display, Examples of Actual or Potential Health Problems and Needs: Middle Adulthood.

Health-related screenings, examinations, and immunizations for adults are outlined in Box 24-2 on page 636. Additionally, the following health promotion activities are recommended:

- Eat a diet low in fat and cholesterol, including fruits, vegetables, and fiber; use sugar, salt, and sodium in moderation.
- Make regular exercise a part of life.
- Drink alcohol in moderation, if at all.
- Do not smoke.

The middle-aged adult needs to know the dangers of substance use disorders and the potential sequelae. Alcohol consumption and binge drinking increased in adults in the United States during the COVID-19 pandemic due to heightened stress and boredom (Gorssman et al., 2020; Pollard et al., 2020; Weerakoon et al., 2021)—the long-term consequences of this are yet to be determined. Referrals to support groups and individual counseling may be necessary to strengthen a middle-aged adult's coping mechanisms and promote acceptance of personal and family changes. Having successfully met developmental tasks, the healthy middle-aged adult is ready to enjoy the rest of life. A sense of continuity and adaptability from the early 20s through the 50s is essential for a person to meet the developmental tasks of aging satisfactorily and to enjoy all remaining years.

Examples of Actual or Potential Health Problems and Needs

MIDDLE ADULTHOOD

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Caregiver Fatigue	• Unrealistic expectations of themselves in the caregiver role • Competing role commitments—sandwich generation • Lack of caregiving experience	• Verbalizations of uncertainty, fatigue, and concern about the care of the person for whom they provide care • Physical manifestations such as

	• Insufficient coping strategies and resilience • Insufficient knowledge of individual, familial, or community resources	yawning, GI upset, inattention, or excessive sleepiness • Decrease in professional productivity • Unwanted changes in physical, psychological, social, emotional, or spiritual self-care activities
Readiness for Positive Family Process	—	• Verbalizations related to family processing—establishing individuality and boundary-setting, while maintaining family connectedness • Adapting to an empty nest—recognition of positives and negatives • Engagement in activities that enhance family resilience • Establishment of adult relationships with children

OLDER ADULTHOOD

Society has arbitrarily labeled a person older than age 65 years as an **older adult**. To account for the diversity that exists among different age groups, the older adulthood is often further divided into the three age classifications: youngest-old (ages 65 to 74 years), middle-old (ages 75 to 84 years), and oldest-old (ages 85 years and older; Eliopoulos, 2022).

American society is aging—dramatically, rapidly, and largely well. With birthrates down and some baby boomers already reaching retirement age, we can estimate that 16.5% of the population is age 65 years or older (Unites States Census Bureau, 2021). In 2021, life expectancy projections for men who reach age 65 increased to age 83.2 and for women who reach age 65 to age 85.8 (CDC, 2021e). Health disparities become magnified in the older adult population. Race, ethnicity, immigration, sex and gender identification, physical and mental disabilities, and economic status all affect access to health care and health outcomes (He et al., 2016). Dwyer-Lindgren et al. (2017) analyzed data from 1980 to 2014 and identified three major sets of factors that explain 74% of the variation in life expectancy at the county level across the United States:

Box 24-2 **Guidelines for Health-Related Screenings, Examinations, and Immunizations for the Aging Adult**

Physical Examination

- Every 3 years until age 40 years
- Every year after age 40 years

Breast Cancer Screening (for Average-Risk People With Female Anatomy)

- There is an emphasis on knowing your own breasts and reporting any changes.
- Mammography screening may be offered beginning at age 40 years but should be initiated every year beginning at age 45 years (American Cancer Society [ACS], 2021) or age 50 years (American College of Obstetricians and Gynecologists [ACOG], 2017/2021); those ages 55 years and older can switch to mammograms every 2 years (ACS, 2021); mammograms should continue through age 75 years (ACOG, 2017/2021).

Cervical Cancer Screening (Females, Beginning at Age 21 Years)

- Females should have a pelvic examination with Papanicolaou (Pap) exam every 3 years for ages 21 to 29 years, and every 5 years for ages 30 to 65 years.
- Females who have had a total hysterectomy (removal of the uterus and cervix) do not need cervical cancer screening, unless the surgery was for cervical precancer or cancer.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Females over age 65 years with no abnormal Pap tests in the last 10 years should consult with their health care provider about continuing cervical cancer screening.

Prostate Exam (Males, Beginning Age 50 Years)

- The prostate-specific antigen (PSA) test should be discussed with the provider; recommend this conversation at age 45 years if the patient is African American or has a family history of prostate cancer.
- Digital rectal examination (DRE) should take place every year.
- Screening is individualized based on health care provider and the person's concerns.

Testicular Cancer Screening (Males)

- There is an emphasis on knowing the testicles and reporting any changes.
- Testicular clinical examination is part of the general physical exam.

Colorectal Cancer Testing (Beginning Age 45 Years)

- Fecal occult blood test should be done every year.
- Digital rectal examination (DRE) should be done every year.
- Flexible sigmoidoscopy should be done every 5 years, *or*
- Colonoscopy every 10 years, *or*
- Double contrast barium enema every 5 years, *or*
- CT colonography (virtual colonoscopy) every 5 years.
- For people **ages 76 through 85 years**, talk with your health care provider about whether continuing to get screened is right for you.
- People **older than age 85 years** should no longer get colorectal cancer screening.

Skin Cancer Exam

- Self-examination should be done every month.
- Clinical skin examination is part of the general physical exam.

Oral Cancer Exam

- Every year as part of medical or dental checkups

Bone Density Testing

- Menopausal and postmenopausal females younger than age 65 years with risk factors, or older than age 65 years
- Males aged 50 to 69 years with risk factors, or older than age 70 years
- Fracture after age 50 years
- Height loss

Vision Exam

- Eye examination, with a test for glaucoma, should be done every 1 to 2 years.

Immunizations (Healthy Adults)

- *Tdap or Td:* Administer one dose Tdap, then Td booster every 10 years.
- *MMR vaccine:* Administer one dose of MMR to adults who previously received ≤2 doses of mumps-containing vaccine and are identified by a public health authority to be at increased risk during a mumps outbreak.
- *Influenza:* Administer one dose every year.
- *Pneumococcal vaccine:* Administer one dose of PCV13 (13-valent pneumococcal conjugate vaccine) for adults ages 65 years and older if not previously received, followed by one dose of PPSV23 (23-valent pneumococcal polysaccharide vaccine) 1 year after dose of PCV13. For adults with certain medical conditions who received a dose of PPSV23 at ages 19 to 64 years, administer a second dose of PPSV23 at age 65 years, followed by a dose of PCV13 1 year later (if not previously received).
- *Zoster Vaccine Live (ZVL) or Recombinant Zoster Vaccine (RZV):* Administer two doses of RZV (Shingrix) 2 to 6 months apart to adults ages 50 years and older regardless of past episode of herpes zoster or receipt of ZVL (Zostavax). Administer two doses of RZV 2 to 6 months apart to adults who previously received ZVL at least 2 months after ZVL. For adults ages 60 years and older, administer either RZV or ZVL (RZV is preferred).

- *Socioeconomic and race/ethnicity factors:* 60% of variation explained by income, population below poverty level, graduation from high school/college, unemployment rate, and race/ethnicity
- *Behavioral and metabolic risk factors:* 74% of variation explained by hypertension, diabetes, obesity, smoking, and physical activity level
- *Health care factors:* 27% of variation explained by number of available health care providers in the area, quality of services, and insurance

Boing et al. (2020) found that more than three fourths of the total variation in life expectancy can be attributed to county of residence in the United States, and that race, education, and income were particularly relevant to explaining the variations in life expectancy. Between 2009 and 2019, the population of older adults (ages 65 and older) in the United States increased from 39.6 million to 54.1 million (16% of the population) and is projected to reach 94.7 million in 2060. Ethnic and racial minority older-adult populations have increased from 7.8 million (20% of older adults) to 12.9 million (24% of older adults), with 2040 projections at 27.7 million (34% of older adults). Although only 8.9% of older adults live below the poverty line, which is a dramatic change from 30% in 1966, economic disparities exist: 18% of Black older adults, 17.1% of Hispanic older adults, 9.3% of Asian older adults, and 6.8% of non-Hispanic White older adults live in poverty (Administration for Community Living, 2021). These numbers directly reflect the need to consider resource allocation as well as policies and programs to assist our aging population.

Unique Population

The older adult population is the most unique group in society today. They have lived the longest and have participated in and adapted to complex societal changes. Older adults have witnessed the development of society from a predominately rural agricultural culture, through industrialization, to a service-oriented, high-technology culture. Technology's influence in the past 50 years in household management, travel logistics, media access, and social connections has changed the way we live our lives. Information that once took weeks or months to be received now is available instantaneously. In fact, most older adults have had some exposure to personal computers and hand-held communication devices, and many are technologically savvy. Most older adults have lived through the trauma of world wars. Many had parents with strong ethnic ties to another country, and many were immigrants themselves. Older adults have lived through the repercussions of and rebuilding after the Great Depression of the 1930s and several recessions. Antiwar movements and experiences in the Vietnam war, Desert Storm, Desert Shield, and other conflicts impact their current views of war and terrorism. The civil rights movement of the 1960s and 1970s shaped their views of race, inequalities, and activism. Although their political affiliation varies, they represent the largest block of voters—52% of registered voters are ages 50 years and older and 24% are ages 65 years and older (Pew Research Center, 2020).

Further adaptations become necessary with advancing age because of physical or cognitive limitations, retirement, loss of a spouse or family members, or changing income. Older adults face numerous role changes related to their age or health status. Lost roles must be replaced with new roles and activities that are acceptable and satisfying to the person.

Recall **Larry Jenkins**, the 67-year-old lamenting that his life has been going "downhill" since he retired. The nurse could incorporate knowledge of role changes to develop an appropriate plan of care for the patient that fosters adjustment to his role changes.

Older people are living in a world that requires them to change and to adapt. Senior years are a time for people to reach their potential and to satisfy long-range goals that may have been delayed because of other responsibilities. It can also be a time for older adults to turn over to others certain tasks, such as career or community leadership. Because of recent economic challenges, some older adults have chosen to remain in the work force out of necessity, while others enjoy the socialization and intellectual stimulation that employment provides. Research has shown that most older adults do adjust and adapt to new roles, and most are satisfied with their lives and with what they have. Depending on the older adult's adaptability and supportive resources, older adulthood may be a time of happiness, peace, and understanding or

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of sorrow, conflict, and confusion.

Personal relationships evolve as people age. Increased mobility of families, multiple external influences, time drains on young families, and technologic advances can weaken intergenerational ties. Establishing new ways to communicate and engage among generations such as texting or social media can help fill this void.

Technology Alert

Adults learn best when the material being taught is relevant to their daily lives and is deemed important in the moment. Using technology to teach technology works to solidify learning and reinforce basic skills, so that more complex skills can be developed. Techboomers.com is a free educational website that serves older adults. Its purpose is to teach "older adults and other inexperienced Internet users … basic computer skills about websites that can help improve their quality of life" (Techboomers, 2018, "Who Are We"). Integrating these types of resources into health promotion activities can have a positive impact on the lives of older adults.

Ageism and Common Stereotypes

Sometimes, an older adult is the victim of ageism. **Ageism** is a form of prejudice, like racism or sexism, in which older adults are stereotyped and discriminated against. Fundamental to ageism is the view that older people are incapable and do not experience the same desires, needs, and concerns as younger adults. Although the process of aging is associated with some normal changes, not all people age at the same rate, and potential functional declines vary in type (e.g., cognitive or physical) and degree. Our industrial technologic world places a high priority on productivity, and some may think that older employees or retired people have outlived their usefulness. It is important to remember that older people are delaying retirement. In 2018, 24% of men and about 16% of women ages 65 years and older were in the labor force, and these numbers are expected to rise (Mather et al., 2019). Making assumptions simply based on a person's age is an example of implicit bias that can lead to discriminatory practices.

Think back to **Larry Jenkins**, the 67-year-old retiree. The nurse could incorporate knowledge of ageism as a basis for obtaining additional assessment data, examining possible factors contributing to the patient's feelings of boredom and uselessness.

Older people may be incorrectly viewed as being rigid or narrow-minded, unable to learn, unreliable because of memory loss, too old to enjoy sexual pleasure, or childlike and dependent. Many people fear advancing age because of pervasive views that older people are living in poverty, lonely, in frail health, and headed for institutionalization in a long-term care facility. These descriptors are not true for most older adults (Fig. 24-2). Common myths about older adults are compared with the realities in Table 24-1.

FIGURE 24-2. This couple, married 61 years, enjoys gardening together. They've found that they can continue most activities with only minor adjustments.

Table 24-1 Myths and Realities About Older Adults

MYTH	REALITY
Old age begins at age 65 years.	Defining 65 years old as *old age* happened arbitrarily when age 65 years was set for Social Security payments in the 1930s, based on the labor market and the economy of that time.
Most older adults live in long-term care facilities.	Although the largest percentage of residents in long-term care facilities are older adults, many of whom have disabilities, only 1% of older adults ages 65–74 years, 2% of older adults ages 75–84 years, and 8% of adults older than age 85 years live in long-term care facilities (Administration for Community Living, 2021).
Most older adults are sick.	81% of older adults ages 65 to 74 years and 68% of older adults older than age 85 years rate their health *good*, *very good*, or *excellent* (Federal Interagency Forum on Aging-Related Statistics, 2020).
Old age means mental deterioration.	Although response time may be prolonged due to a longer processing time, neither intelligence nor personality normally change because of aging.
Older adults are not interested in sex.	Although sexual activity may be less frequent, the ability to perform and enjoy sexual activity lasts well into the 90s in healthy older adults.
Older adults do not care how they look.	Older adults want to be attractive to others.
Most older adults are isolated and lonely.	Loneliness results from death of loved ones or other losses, just as it does for people of all ages. Many older adults participate in social and community activities.
Bladder problems are a problem of aging.	Incontinence is not a part of aging; it generally has a root cause and requires medical attention.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Older adults do not deserve aggressive treatment for serious illnesses.	Older adults deserve aggressive treatment if they want it.
Older adults cannot learn new things.	Many older adults today are more educated than previous generations, and have had to adapt to technologic advances; they continue to use technology into old age.

Box 24-3 **Normal Physiologic Changes of Older Adults**

General Status

- Progressively decreasing efficiency of physiologic processes results in a fragile balance and hinders the body's ability to maintain homeostasis.
- Physical or emotional stressors cause the older adult to be more vulnerable because of decreased physiologic reserves.
- The older adult may continue to engage in all activities of middle age but intuitively adjusts to a modified pace and more frequent rest periods.

Integumentary System

- Wrinkling and sagging of skin occur with decreased skin elasticity; dryness and scaling are common.
- Balding becomes common in males, and females also experience thinning of hair; hair loses pigmentation.
- Skin pigmentation and moles are common, although the skin may become pale because of loss of melanocytes.
- Nails typically thicken, becoming brittle and yellowed.
- The blood vessels in the dermis become more fragile, causing increased bruising and purpura (hemorrhaging into the skin).

Musculoskeletal System

- Decreases in subcutaneous tissue and weight commonly are found in the oldest-old.
- Muscle mass and strength decrease.
- Bone demineralization occurs; bones become porous and brittle. Fracture is more common.
- Joints tend to stiffen and lose flexibility, and range of motion may decrease.
- Overall mobility commonly slows, and posture tends to stoop. Height may decrease 1 to 3 inches.

Neurologic System

- The central nervous system responds more slowly to multiple stimuli. Hence, the cognitive and behavioral response of the older adult may be delayed.
- Rate of reflex response decreases.
- Temperature regulation and pain/pressure perception become less efficient.
- There may be a loss of sensation in the extremities.
- The older adult may also experience difficulty with balance, coordination, fine movements, and spatial orientation, resulting in an increased risk for falls.
- Sleep at night typically shortens, and the older adult may awaken more easily. Catnaps become common.

Special Senses

- Diminished visual acuity (presbyopia) occurs, with increased sensitivity to glare, decreased ability to adjust to darkness, decreased accommodation, decreased depth perception, and decreased color discrimination. Cataracts may further obscure vision. As a result of these changes, the older adult may have difficulty reading small print, and daytime or night driving may be compromised.
- Diminished hearing acuity (presbycusis) occurs, particularly diminished pitch discrimination in the presence of environmental noises. Cerumen (wax) buildup is common. As a result of hearing problems or amplification issues with hearing aids, the older adult may withdraw from social events.
- The senses of taste and smell are decreased. Sweet and salty tastes diminish first. Sensitivity to odors may be reduced. Problems with nutrition may result.

Cardiopulmonary System

- Blood vessels become less elastic and often rigid and tortuous. Venous return becomes less efficient. Fatty plaque deposits continue to occur in the linings of the blood vessels. Lower-extremity edema and

cooling may occur, particularly with decreased mobility. Peripheral pulses are not always palpable. Orthostatic hypotension can occur.
- The body is less able to increase heart rate and cardiac output with activity.
- Pulmonary elasticity and ciliary action decrease, so that clearing of the lungs becomes less efficient. Respiratory rate may increase, accompanied by diminished depth.

Gastrointestinal System

- Digestive juices continue to diminish, and nutrient absorption decreases.
- Malnutrition and anemia become more common.
- With reduced muscle tone and decreased peristalsis, constipation and indigestion are common complaints.
- Diminished saliva production leads to dry mouth problems.

Dentition

- Tooth decay and loss continue for most older adults.
- Eating habits may change, particularly if the older adult lacks teeth or has ill-fitting dentures.

Genitourinary System

- Blood flow to the kidneys decreases with diminished cardiac output.
- The number of functioning nephron units decreases by 50%; waste products may be filtered and excreted more slowly.
- Fluids and electrolytes remain within normal ranges, but the balance is fragile.
- Bladder capacity decreases by 50%. Voiding becomes more frequent; two or three times a night is usual (nocturia). A decrease in bladder and sphincter muscle control may result in stress incontinence or incomplete bladder emptying (overflow incontinence).
- About 75% of males over 65 years of age experience benign (not cancerous) hypertrophy of the prostate gland (BPH); surgery may be required if urinary retention occurs.
- The older female's genital tract atrophies and is associated with thinning and a decrease in vaginal secretions.

Physiologic Development

In older adults, all organ systems undergo some degree of decline in overall functioning, and the body becomes less efficient. Normal physiologic changes in structure and function of the body with aging are outlined in Box 24-3. Body functions that require integrated activity of several organ systems are affected the most. For example, aging of the cardiac muscles causes fluid retention in both peripheral tissues and the lungs, causing swelling of the legs and making breathing more difficult. The most commonly encountered chronic disorders are hypertension, arthritis, heart disease, cancer, diabetes, respiratory disorders (chronic obstructive pulmonary disease and asthma), and stroke (CDC, 2021e; Federal Interagency Forum on Aging-Related Statistics, 2020).

Recall **Ethel Peabody**, the 88-year-old woman with dementia and cardiac problems. Knowledge of physiologic changes associated with aging could help with developing an appropriate plan of care for this patient after discharge.

Most older adults regard themselves as healthy. In fact, 81% of older adults ages 65 to 74 years and 68% of older adults older than age 85 years rate their health *good*, *very good*, or *excellent* (Federal Interagency Forum on Aging-Related Statistics, 2020). There is growing evidence that aging is not synonymous with disability and loss of function. Like younger adults, older adults define their health in relation to how well they function. Functional health includes the ability to remain self-reliant, to compensate, and to maintain a sense of independence and control over self and environment.

There is a trend in health care today toward fostering increasing independence and self-care in older adults. Those

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

who live alone are at greatest risk for loss of independence and increased need for assisted living or long-term care. Most older adults are never institutionalized, nor do they experience the effects of senility. Being healthy, however, does not necessarily mean living without disease. Most older adults have at least one chronic disorder and typically have at least two (Eliopoulos, 2022); their ability to adapt determines whether they are ill or healthy. Most older adults continue their activities from middle age and adapt intuitively to the gradual limitations of aging; it may take longer to complete an activity, or the activity may need to be modified. For example, an older adult with arthritis may need to use an electric can opener rather than a manual one, or a person with heart disease may need 3 hours to garden, resting several times, rather than the 1-hour gardening used to require.

Concept Mastery Alert

As people age, their ability to adapt, not the time it takes for them to adapt, is the key determinant for whether they will be ill or healthy.

Sarcopenia is the loss of muscle mass that frequently occurs in older adults as part of the natural aging process. The clinical definition of sarcopenia has been expanded to include a decrease in muscle mass that is assessed by handgrip strength, and a decrease in physical function that is assessed by gait speed (Eliopoulos, 2022). *Sarcopenic obesity* describes the muscle loss combined with obesity (an increase in body fat) as people age (Lee et al., 2016). This condition can result in loss of strength and function and a reduced quality of life that is significant for older adults. Since sarcopenia is mostly seen in inactive older adults, exercise that includes resistance training and adequate dietary protein are management strategies that can prevent or reverse this process.

FIGURE 24-3. The hospitalized older adult requires nursing interventions to prevent complications. (*Source:* Used with permission from Shutterstock. *Photo by Kathy Sloane.*)

Remember **Ethel Peabody**, the woman described in the Reflective Practice box on page 631. The nurse can apply knowledge about functional health to determine the patient's needs for safety and independence while, at the same time, fostering a positive self-image.

The greatest threat to the health of older adults is loss of the physiologic reserve of the various organ systems. When illness occurs, increased physical and emotional stress places an older adult at risk for complex reactions. An older adult is more likely to develop complications and to recover more slowly (Fig. 24-3). For instance, an older adult with a hip fracture is at high risk for pneumonia and skin breakdown because of immobility, a decreased ability to mobilize pulmonary secretions, and thinner, more fragile skin.

Unfolding Patient Stories: Josephine Morrow • Part 1

Josephine Morrow is 80 years old and developed a venous stasis ulcer on her lower extremity as a community-dwelling older adult. She recently moved to a skilled nursing home. What are normal physiologic changes the nurse should consider when caring for older adults? How can the nurse help Josephine adjust to long-term care and her loss of independence? (Josephine Morrow's story continues in Chapter 28.)

Care for Josephine and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

Cognitive Development

The term *cognition* indicates cerebral functioning, including a person's ability to perceive and understand their world. Cognition does not change appreciably with aging. In fact, intelligence increases into the 60s, and learning continues throughout life. It is normal for an older adult to take longer to respond and react, particularly in new or unfamiliar surroundings. Knowing this, the nurse should slow the pace of care and allow older adults extra time to ask questions or complete activities. Mild short-term (recent) memory loss is common but can be remedied by an older adult using notes, schedules, and calendars. Long-term memory usually remains intact. Dementia, Alzheimer's disease (AD), depression, and delirium may occur and cause cognitive impairment. These conditions are discussed later in relation to the health of the older adult.

Psychosocial Development

Most theorists agree that a person's self-concept is relatively stable throughout adult life. An older adult who has a strong sense of self-identity and has successfully met challenges earlier in life will probably continue to do so. This person substitutes new roles for old roles and perhaps continues former roles in a new context. For example, business managers after retirement may continue to use their leadership talents in community or volunteer organizations. Older adults with a strong self-concept typically describe themselves as being healthier than others or "young for my years." Maslow, in his hierarchy of human needs, describes the level of self-actualization as the desire to become the most that one can be. A self-actualized person has realistic perceptions of self, is a problem solver, is usually spontaneous, needs time to focus on their individual potential, and views the world with a sense of appreciation. On the other hand, events that may accompany aging can threaten a person's self-concept. Depending on the person's outlook on life and past ability to cope, events such as retirement, loss of health or income, loss of ability to operate a motor vehicle, and isolation can be devastating. For example, a retired teacher whose sense of identity was closely tied to career may suddenly be in the position of having lost friends, income, and sense of accomplishment, and may consequently feel a loss of control and self-identity.

The loss of the privilege of driving has serious repercussions for older adults. Aging results in slower reaction times and changes in vision, such as increased sensitivity to the glare from approaching headlights as well as alterations in peripheral vision. Certain adjustments can prolong an older adult's ability to drive safely. These include driving only during daylight hours and avoiding travel at stressful times such as morning and evening rush hours. Keeping a safe distance from the car ahead and a watchful eye on unsafe weather conditions are also helpful.

When it becomes obvious for safety reasons that an older driver should stop driving altogether, it is best if family members address their concerns with the older adult in an honest, forthright manner. The U.S. Department of Transportation is an additional resource; state branches may request that an older driver be retested based on identification of a concern from a health care provider, a police or accident report, or written expressed concern from a family member. As the number of older drivers increases, so do the challenges to promote safe driving and find alternatives to driving (National Highway Traffic Safety Administration, n.d.).

Losing driving privileges is disheartening and can cause older adults to feel anxious and lonely, which may be viewed as another negative consequence of aging. This lack of independence may also result in less opportunity for activities or interactions with friends and family. The availability of alternative means of transportation should be explored. Some older adults take advantage of transportation services through their communities, or use ridesharing services such as Lyft or Uber.

Disengagement Theory

An early psychosocial theory, called the *disengagement theory*, maintained that older adults often withdraw from usual roles and become more introspective and self-focused. This withdrawal was theorized as intrinsic and inevitable, necessary for successful aging, and beneficial for both the person and for society.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Later studies showed that isolation is not desired or acceptable, and that as societal interactions decrease, healthy older adults increase their close relationships with family and friends. According to the *activity theory*, successful aging includes the ability to maintain high levels of activity and functioning. An older adult may substitute activities, but does not slow down or disengage from society. The *continuity theory* assumes that healthy aging is related to the older adult's ability to continue similar patterns of behavior from young and middle adulthood (Eliopoulos, 2022; Miller, 2019).

Erikson's Theory

Erikson (1963) identified ego integrity versus despair and disgust as the last stage of human development, which begins at about age 60 years. Older adults continue to look forward, but now also look back and begin to reflect on their lives. It is a time for realization of a *wholeness* perspective, with an inner search for meaning and order in the life cycle. Older adults search for emotional integration and acceptance of the past and present, as well as acceptance of physiologic decline without fear of death.

Older adults often like to tell stories of past events. This phenomenon, called **life review** or **reminiscence**, has been identified worldwide. Reminiscence is a way for older adults to relive and restructure life experiences, often in relation to their current situation, and with the added benefit of the perspective provided by life experience and wisdom. Although reminiscence therapy is often used in patients with mild to moderate dementia, reminiscence has value for older adults who do not have cognitive or memory impairments (Fig. 24-4 on page 642). Nurses use reminiscence therapy to encourage reflection and facilitate adaptation to present circumstances.

Think back to **Larry Jenkins**, the 67-year-old man described at the beginning of the chapter. The nurse could use life review to foster Mr. Jenkins' ego integrity.

FIGURE 24-4. Reminiscing is a culturally universal phenomenon of aging. It is a way for the older adult to reassess life experiences and further develop a sense of accomplishment, fulfillment, and reward in life.

Ego integrity is facilitated when an older adult has successfully accomplished tasks that were identified earlier in life. Older adulthood can be a time for the person to look backward with pride and without regrets, and to look forward with optimism and enthusiasm. A person who regrets the past and sees current problems as insurmountable may despair. This person may view life as a series of unresolved problems and missed opportunities, and feel worthless or hopeless. A person in despair may want to do things over but fears the lack of time before death.

The tasks of midlife continue or may resurface. Older adults still strive to guide the coming generations and to leave something behind (generativity vs. stagnation). Their need for love and closeness continues (intimacy vs. isolation), as does a strong sense of who they are in relation to family and community (identity vs. role confusion). Because of physical and social changes associated with aging, older adults are repeatedly faced with the need to adapt and to repeat already completed tasks.

Havighurst's Theory

According to Havighurst (1972), the major tasks of old age are primarily concerned with the maintenance of social contacts and relationships. Successful aging depends on a person's ability to be flexible and adapt to new age-related roles. The person must find new and meaningful roles in old age while being reasonably comfortable with the social customs of the times.

Adjusting to the Changes of Older Adulthood

Older adults use their years of experience as a guide for adjusting to the changes that come with increasing age. These changes, based on Havighurst's tasks for later life, involve many areas of life, as described in the following sections.

Physical Strength and Health

Most older adults gradually modify their lifestyle to accommodate for declining strength and health. They rest more frequently, although continued activity and exercise are important for maintaining all physiologic functions. Diet modifications and prescribed medications may be necessary. Sleep disorders may develop, especially in women as they age (Sivertsen et al., 2021), and may contribute to daytime sleepiness, a slower response time, impaired memory, and behavior that may be mistaken for some form of cognitive impairment. Confusion and cognitive impairment in an older adult are not normal consequences of aging. An alteration in cognition or mental status that is new should be considered an acute problem and considered in relation to infection, polypharmacy, or other factors (Fitzgerald et al., 2017). An older adult is at high risk for accidents and falls and may need to curtail driving or use a cane or other aid to remain mobile.

Because of chronic illness, an older adult may need to adjust to living with some pain. Pain should not be assumed to be a normal consequence of aging, but it is often experienced by older adults and frequently is undertreated. Attitudes toward treating pain in this population may interfere with optimum pain relief. Providers and patients need to collaborate to differentiate mild chronic discomfort that may be related to the normal processes of aging, and acute or chronic pain that interferes with a functional lifestyle and requires intervention. Additional information about pain management for older adults can be found in Chapter 36. Delirium, sleep disturbances, cognitive changes, and diminished functional abilities may occur when pain is not managed adequately.

Because of the interplay between complex comorbidities, disease progression, and the expected changes with aging, loss of independence can occur. The loss of health is difficult to adjust to because it affects every aspect of life.

Retirement and Reduced Income

Retirement brings a change in a person's concept of time. Many older adults must learn to occupy their leisure time in ways that maintain their self-esteem while being personally satisfying. Satisfaction with retirement is closely tied to income and the relationships one has outside of work. While many older adults have adequate retirement income, for others, a lack of adequate income can affect their ability to meet their needs, such as for medical care and housing or social and creative interests.

Spouse or Partner Health

When a person's spouse or partner becomes ill, numerous and difficult adjustments must be made. An older adult may face new roles for the first time, such as cooking meals or handling family finances. These role changes come at a time when stress is already high. Providing physical care can be an overwhelming task if the caregiver is also frail or in poor health. Adaptations may be needed in living conditions and lifestyle, and one spouse may need to plan social and recreational events alone. Take a moment and reflect on the poem by Amy Haadad in the Poetry Nook.

The need for love and belonging does not diminish with age, and may become acute with the loss of the spouse or partner through illness or institutionalization. Humans are sexual beings, and sexual behavior does not necessarily stop in old age. Like younger adults, older adults need to experience intimacy physically by touching and sexual activity, and emotionally by sharing joys, sorrows, ideas, and values (Fig. 24-5).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 24-5. Stereotypical images of the older adult as narrow-minded, forgetful, sexless, and dependent are untrue of most older adults. This couple exhibits the vitality, sensuality, joy, and playfulness of a young couple.

Poetry Nook

Landlines

Stubborn to the point of silence
she was determined to live on her own,
willing to let strangers into her home
to help her shower, see her naked.
These invasions into her privacy
were the price she paid to be free
to roam from room to room and be
alone at night. Nights were the worst
for me. I would clutch the ragged worry
each night, imagine her somewhere in
her house injured and helpless, lying
by the oxygen concentrator till dawn.
I put two phones in her bedroom.
I would reason she could crawl to one
for help. One next to her recliner where
she often slept, the other a red, rotary
phone hard-wired in the bathroom
with a ring like an air raid siren.
Her body failed her in diverse ways

but never her mind. No matter the number
of calls in a day, we always talked
at bedtime. When she didn't answer
right away I'd hang up, wait a bit
counting her slow steps in my head,
then try again. One night, I got no
answer. Too late for her to be out.
I pictured her motionless
on the kitchen floor, oxygen tubing
spaghettied around the legs of her walker,
a hazard we feared but lived with.
I dialed again, let it ring
forever. No answer. I drove, too fast,
to her house punched in the garage code,
flew inside, yelled, *Mom! Mom!*
The house was still except for the murmur
of the oxygen concentrator.
Night lights like luminaries marked
the way to the bedroom. She was not
on the floor or in her chair or bed.
I turned to the bathroom. There she was,
on the toilet, arms resting
on the metal safety rails, softly snoring,
her pink nylon underpants
around her ankles, the red phone planted
squarely between her bare feet.

FIGURE 24-6. Social relationships and satisfying leisure activities remain important throughout life. This older adult volunteers in art class with sixth-grade students. (*Source:* Used with permission from Shutterstock. *Photo by Kathy Sloane.*)

Relating to Age Group

As the population ages, social organizations for older adults are becoming more numerous. For example, most communities have senior citizens' centers that offer meals, social and informational programs, and other activities for a nominal fee. Other organizations offer opportunities for travel, cultural events, and political involvement. Affiliation with people of the same age allows older adults to share common interests and concerns, and to find status among their peers. Some adults reside in retirement communities that provide a multitude of opportunities for social engagement. It should not be assumed, however, that older adults want to associate only with others their age; intergenerational friendships can be mutually beneficial and extremely rewarding (Fig. 24-6).

Social Roles

Social roles change with the developmental tasks and adjustments of older adulthood, but the need to feel valued, useful, and productive continues. Older adults may develop new hobbies or increase their involvement in community, church, or family affairs (Fig. 24-7). They may do volunteer work or even begin a new career. If an older adult cannot adjust and form new relationships, social isolation can become a problem. **Social isolation** is a sense of being alone and lonely as a result of having fewer meaningful relationships. It may occur because of declining health or income, transportation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

problems, or ageism. Whatever the cause, prolonged social isolation has been associated with declining health and higher mortality rates. Unfortunately, the COVID-19 pandemic provided insight into the negative effects of social isolation on older adults caused by the social distancing and quarantining imposed by local/state/national mandates and health care policies intended to minimize transmission of the virus. The effects of social isolation on older adults included anxiety, depression, and despair. Older adults with dementia who were isolated suffered further cognitive decline (Chu et al., 2020). For older adults, reported sources of joy and comfort during the pandemic involved strengthened family relationships and friendships; the discovery of digital social contact; and a resurgence of hobbies fueled by re-engagement with self-care, exercise, faith, and nature (Whitehead & Torossian, 2021).

Concept Mastery Alert

Social isolation is different from ineffective coping. Social isolation is the feeling of being alone; ineffective coping refers to difficulty in adapting or responding to the changes associated with the situation. Ineffective coping can lead to social isolation.

FIGURE 24-7. Older adults who exercise regularly improve their physical strength as well as overall stamina, mood, and mental health. Opportunities for engagement outside the home may involve the use of technology, which stimulates continued growth in the older adult, and may increase their feelings of personal control and engagement. (*Source: Bottom Photo by Rocketclips, Inc./Shutterstock.*)

Vulnerable Population Alert: Residents of Long-Term Care Facilities

If we learned anything during the COVID-19 pandemic, it is how vulnerable the residents in nursing homes are as well as their caregivers. About 5% of U.S. cases and nearly 40% of deaths attributed to COVID-19 have occurred in these long-term facilities, making them “ground zero” in the crisis. Sadly, the problems COVID-19 highlighted were hardly the beginning of what we know about deficient care in long-term care facilities. A stunning article in *The New York Times* (Silver-Greenberg & Gebeloff, 2021), described how nursing homes manipulate the rating systems about the quality of care provided by nursing homes and deceive the public. You may be choosing a five-star (top rating) nursing home for a loved one and have no idea about the fact that homes that received this rating masked serious problems, such as residents developing bed sores so severe that their bones were exposed. Others lost the ability to move.

Highlighting the challenges of staffing these homes, the *NYT* article describes a nursing home operating

in 2017 with a skeleton crew. “Overwhelmed employees of the 120-bed facility would wake some residents as early as 3:30 AM to get them dressed for breakfast and they would put the residents back to bed to wait the hours until mealtime.” In a lawsuit brought by a resident, charges included:

More than a week passed before Ms. Johnson was first given a shower, her medical records show. Her surgical wound was not treated. No one came when she rang her call bell for help going to the toilet, so she sat for hours in her own urine and feces. At one point, … a passing maintenance man changed her diaper.

Silver-Greenberg, J., & Gebeloff, R. (March 14, 2021). To life ratings, nursing home shroud neglect. *The New York Times*.

Kolanowski, A., Cortes, T. A., Mueller, C., Bowers, B., Boltz, M., Bakerjian, D., Harrington, C., Popejoy, L., Vogelsmeier, A., Wallhagen, M., Fick, D., Batchelor, M., Harris, M., Palan-Lopez, R., Dellefield, M., Mayo, A., Woods, D. L., Horgas, A., Cacchione, P. Z., … Gerdner, L. (2021). A call to the CMS: Mandate adequate professional nurse staffing in nursing homes. *The American Journal of Nursing*, *121*(3), 24–27. https://doi.org/10.1097/01.NAJ.0000737292.96068.18

Living Arrangements

Most older adults live in a community. In 2020, 61% of older adults living in a community lived with their spouse or partner, and 27% lived alone (20% of older men and 33% of older women). The number of older adults living alone increases with age. Relatively few older adults live in long-term care facilities (1% of older adults ages 65 to 74 years; 2% of older adults ages 75 to 84 years), but that number increases with age (8% for adults older than age 85 years), and as their needs increase (Administration for Community Living, 2021). When a person moves to a long-term care facility, the loss of home and possessions and the need to conform to the routines of institutional living can be traumatic for the person and family. Some people, however, choose to move for convenience, social relationships, or needed health care. Reflect on the Vulnerable Populations Alert that focuses on standards related to staffing and quality care in long-term care facilities.

Various types of housing options for older adults are outlined in Box 24-4 on page 646. The ability to function safely and independently at home depends a great deal on a person’s functional health, transportation, income, and family. An older adult, for example, may need assistance with home repairs, housecleaning, or grocery shopping. Architectural barriers, such as steps, may need to be modified. Easy access to medical and recreational facilities and churches may become more important. Many older adults in poor health can continue living at home with some assistance from visiting nurses or with the aid of other services, such as home-delivered meals and senior transportation. Assisted-living housing is becoming more common, providing such requirements as meals, health care services, and cleaning services. Additional options for older adults include quality patient-centered programs with a focus on providing long-term care to older adults who want to remain in the community. Several examples are listed in Box 24-5 on page 647.

Retirement centers and senior citizens’ housing have become common. For the family members of older adults who need health care, alternative methods of care have become available. Examples include respite care facilities, which allow the family a needed rest by temporarily housing and caring for an ailing older family member, and adult day services (ADS) centers, which provide a safe, stimulating environment during the day when family caregivers must work. Nurses should be knowledgeable about what health care and social services are available in the patient’s community so that the patient and family can be referred (AARP, 2019).

Remember **Ethel Peabody**, the 88-year-old woman with early dementia who lives alone. The nurse could work with social services to investigate possible community support resources available for the patient so that she can safely maintain her independence as much as possible.

Family and Role Reversal

An older adult’s spouse or partner and other family members are natural support systems that help the person maintain functional health and independence to meet the developmental tasks of old age. Most older adults maintain close ties with their families; however, 38% of Medicare beneficiaries report feeling less socially connected to their families and friends (Administration for Community Living, 2021). Supportive assistance may include providing transportation, food, shelter, social interactions, and even complex medical and nursing treatments. Significant others, such as close friends and neighbors, may also take on tasks formerly assumed to be the responsibilities of the immediate family.

Not all families can assist an aged member satisfactorily because of geographic distance, low income, poor health,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

strained marital relationships, or infringement on career or lifestyle. Adult children may feel "sandwiched" between responsibilities for their own children and careers and the needs of older parents. It can be a guilt-ridden and emotionally draining time for all involved when an older adult's physical or emotional illness causes a reversal of roles. This situation can strain family resources.

Box 24-4 Housing Options for Older Adults

Home modification: By making changes, older adults may be able to stay in their own homes. Examples of modifications are replacing doorknobs with handles, replacing faucet handles with levers, and installing grab bars in bathtubs. Older adults with disabilities may require additional modifications and support resources.

Accessory apartment: A separate apartment is constructed in part of an existing house, such as a basement, attic, or converted garage, or as a home addition. This allows older adults to live independently and privately while not being alone.

Assisted-living facility: These facilities generally provide housing, group meals, personal care, support services, and social activities in a social setting. Some health care may be provided. Costs vary from around $29,000 to $66,000 annually depending on location. Some states pay for personal care services for those with limited incomes.

Board and care homes, adult family homes, and adult group homes: Smaller in scale than assisted-living facilities, these services provide a room, meals, and help with daily activities. They may be licensed or unlicensed. Costs average $33,000 per year for a private room; Supplemental Security Income (SSI) will help pay for those with very limited incomes.

Continuing care retirement community (CCRC): This type of housing community offers several options and services, depending on the needs of the resident. Residents usually begin by living independently in apartments, and then move to an assisted-living facility on the same grounds. A skilled nursing center is also part of the community and available when needed. Sometimes called "aging-in-place" models, this type of housing tends to be expensive.

Elderly cottage housing opportunities (ECHO): ECHO homes are small portable cottages that are placed (most often) in the yard of an adult child's home. These units typically cost $28,000 or more, but do allow living independently while still close to support.

Home sharing: Two or more people may share an apartment or house. Each person usually has a private bedroom and shares the other living spaces. These homes may be sponsored by faith-based groups or community facilities.

Long-term care facilities: These facilities provide skilled nursing care or long-term care, including meals, personal care, and medical care. Bedrooms and bathrooms may be shared. Costs average $66,000 per year, but many are more expensive. Medicare provides only short-term coverage following a hospitalization. Medicaid provides coverage for low-income, low-asset people.

Naturally occurring retirement community (NORC): NORCs are neighborhoods or locations that happen to have a significant number of older adults in residence. Although they may occur naturally, their existence provides an opportunity to focus funding and other resources for older adults in the community.

Senior retirement communities, niche retirement communities, and villages: A grouping of rental apartments, condominiums, townhomes, or houses for residents who can take care of themselves and are mobile. Meals, grocery shopping, home repair, and housekeeping services may be offered (at additional cost). Social and recreational activities are usually offered.

Additional information about these housing options is provided by AARP at https://www.aarp.org/livable-communities/archives/info-2014/housing.html

Although moving in with adult children creates changes in roles and authority and can lead to stress on the adult child(ren), older adults often remain in the caretaking role. In 2019, approximately 1.1 million grandparents older than age 60 years lived in a home with one or more grandchildren and provided their basic needs. Of the 5.37 million people with intellectual and developmental disabilities who live with a family caregiver, 24% have adult caregivers ages 60 years and older (Administration for Community Living, 2021).

The nurse must view the whole family as the recipient of care and assess the family for capabilities and limitations for assisting the aged member. The nurse can help ease the strain by listening to the patient's and family's concerns and by validating the importance of family needs. The nurse assists the patient and family to find workable solutions and may refer the family to community support services.

Moral and Spiritual Development

Older adults, according to Kohlberg (1969), have completed their moral development. Most are at the conventional level, following society's rules in response to others' expectations. Spiritually, an older adult may remain at an earlier

level, often at the individuative–reflective level. Many older adults, however, demonstrate conjunctive faith, where they integrate faith and truth to see the reality of their own beliefs, or universalizing faith, where they trust a greater power and believe in the future.

Another perspective on moral and spiritual development in older adults is the theory of **gerotranscendence**, which describes the transformation of a person's view of reality from a rational, social, individually focused, materialistic perspective to a more transcendent vision. This new vision is manifest by maturity, wisdom, spirituality, changes in perceptions of time and space (disappearance of distance), a decreased emphasis on superficial relationships, and, ultimately, life satisfaction (Tornstam, 1994). As a person ages, spirituality and transcendence are a resource and a source of strength when the person is faced with inevitable change and loss.

Health of the Older Adult

As the number of older adults increases, nurses will spend more time providing care for this population. Older adults can require care across all spheres of practice, including hospitals, long-term care facilities, emergency departments, outpatient surgeries, and homes. Nursing care for older adults should be based on two principles:

- Most older people are not impaired. They are functional members of the community who benefit from health-oriented interventions.
- Older people are more vulnerable to physical, emotional, and socioeconomic problems than people in other age groups. They may require special attention to health promotion and maintenance.

Government facility charged with protecting health through the delivery of human services

This section provides a broad introduction to the health care needs of the older adult in terms of chronic illness, accidental injuries, and acute illness.

Chronic Illness

The probability of a person becoming ill increases with age. Chronic health problems or disability also may result from acute illnesses or accidents such as pneumonia, fractures, motor vehicle accidents, and falls. The leading causes of death in adults ages 65 years and older are heart disease, cancer, chronic respiratory disease, stroke, AD, and diabetes (CDC, 2021d).

Although illness affects all dimensions of a person regardless of age, older adults have to contend with a variety of problems as they live with chronic illness. Aging is a normal process, and chronic illness is a pathologic process, but both often occur at the same time. Compensatory mechanisms that may have worked when older adults were younger are no longer sufficient because of the cumulative effects of chronic disease and the negative effects of aging on physiologic compensation. The interrelated changes of aging and the needs imposed by chronic illness increase the risk for problems in all areas of life, including—but not limited to—self-care, lifestyle, economics, social factors, and living arrangements. Chronic health conditions can negatively affect an older adult's functioning and quality of life, but many of these negative outcomes can be prevented or modified with behavioral interventions.

Think back to **Ethel Peabody**, the 88-year-old woman with early dementia and cardiac disease. The nurse could use knowledge about chronic illness as a basis for a teaching plan that addresses the patient's increased needs for safety.

IMPLICATIONS FOR HEALTH CARE

Consider the following:

- In 2020, 94% of community-dwelling older adults (ages 65 years and older) were covered by Medicare, which covers approximately half of acute health care costs. This is important because most older adults have at least one chronic illness, and many have multiple chronic diseases or conditions (Administration for Community Living, 2021).
- Hospitalization costs continue to rise, and the price of high-quality, long-term care may well be beyond the patient's or family's ability to pay.
- Special diets, special equipment, and medical supplies increase economic difficulties.
- In 1966, 29% of older adults (ages 65 years and older) lived below the poverty level. Although this percentage decreased to 10% in 2014 and 8.9% in 2020, meeting the expenses of health care is often difficult for older adults and their families. Women and those 75 years and older are more likely to live in poverty. Non-Hispanic White older adults are less likely than their Black, Asian, and Hispanic counterparts to live in poverty (Administration for Community Living, 2021; Federal Interagency Forum on Aging-Related Statistics, 2020).
- Medication costs related to chronic illness typically continue for the rest of a person's life, with multiple medications being the rule rather than the exception.
- **Polypharmacy**, the use of many medications at the same time, can pose many hazards for older adults. Complicated regimens need careful review to minimize risks and complications and maximize benefits. Polypharmacy, drug duplication, and unmonitored or unreported use of nonprescription medications can lead to negative outcomes. Pharmacists and other members of the interprofessional health care team need to educate and counsel older adults on these potential issues to minimize the risk for adverse effects, toxicities, and drug–drug interactions (Kinsey & Nykamp, 2017; see Research in Nursing: Bridging the Gap to Evidence-Based Practice).

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Interprofessional Collaborative Practice (IPCP) Models

Our population is aging. Older adults are projected to outnumber children younger than age 18 years by the year 2034 (U.S. Census Bureau, 2019). Although Interprofessional Collaborative Practice (IPCP) models, such as Programs of All-Inclusive Care for the Elderly (PACE) or the Doctors Assisting Seniors at Home (DASH) program, provide an effective means for supporting and keeping older adults in the community setting, they continue to be underutilized in the Unites States.

Related Research

Montano, A. R., Shellman, J., Malcolm, M., McDonald, D., Rees, C., Fortinsky, R., & Reagan, L. (2020). A mixed methods evaluation of GOT care!. *Geriatric Nursing*, *41*(6), 822–831. https://doi.org/10.1016/j.gerinurse.2020.04.016

Geriatric Outreach and Training with Care! (GOT Care!) began as a quality improvement project; this study used convergent parallel mixed methods (quantitative and qualitative) design to explore Emergency Department (ED) visit frequency and the related perceptions of stakeholders. GOT Care! required collaboration between geriatric nurse navigators (a new position within the community health system created for this program) and nursing, medicine, dentistry, pharmacy, physical therapy, public health, and social work students and faculty from a public university. After an interprofessional education (IPE) 2-day intensive for the students, geriatric nurse practitioner–led teams completed a geriatric-focused, comprehensive, in-home assessment on community-dwelling older adults. The interprofessional team then crafted a care plan that was shared with the older adult's primary care provider (PCP). The geriatric nurse navigator coordinated care. Weekly meetings over the course of the semester and a follow-up in-home visit by the interprofessional team focused on enacting community resources in an effort to decrease ED visits. Five cohorts (five semesters) of students and 51 community-dwelling older adults participated in GOT Care!. Although the ED visits did not decrease significantly at 6 or 12 months, a decrease was seen at 18 months. Combined with the qualitative data collected regarding perceptions of GOT Care!, this finding indicates that there may be significant long-term benefits of IPCP. Findings of the mixed methods study also indicate that GOT Care! may be more effective for high-risk (multiple comorbids, polypharmacy, diabetes, high-frequency ED visits baseline) community-dwelling older adults with specific demographics, which will help in future implementations of this and similar initiatives.

Relevance to Nursing Practice

The integration of IPE and IPCP teams in practice provides opportunities for growth and development for the professionals involved. One of the key themes identified in this study reinforces what is documented in the literature: "when the client benefits, the team benefits" (p. 828). Although the formation of IPCP teams requires intentionality and consideration of logistics, IPCP interventions can lead to improved outcomes for community-dwelling older adults, specifically surrounding ED visits and hospitalizations. Training students to capitalize on the strengths of their teammates facilitates the development of effective nurse-led IPCP teams in practice.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Nurses must be able to recognize adverse drug reactions in the older adult population instead of mistaking them for age-related changes. Refer to Chapter 30 for additional information regarding altered drug response in older adults.
- Family members must learn how to cope with the needs of the ill person. These needs include personal hygiene, medication administration, special diets, elimination, activities of daily living, and recognition of symptoms that necessitate medical attention.
- Family members must also adapt to psychological stressors such as changes in communication, changes in roles (e.g., an older parent becoming dependent on their adult children), and changes in their own lifestyles as they become the caregivers or share caregiving responsibilities.

QSEN POLYPHARMACY

Polypharmacy, the use of many medications at the same time, requires careful monitoring to minimize the risk for adverse effects, toxicities, and drug–drug interactions.

DIVERSITY AND CHRONIC ILLNESS

As the U.S. population ages dramatically and becomes more diverse, it is important to consider how cultural differences can affect future patterns of disease, disability, and health care use. Minority populations continue to grow. Projections indicate that by 2060, 23% of Americans will be ages 65 years and older. In 2018, 77% of older adults identified as non-Hispanic White; this percentage is projected to drop to 55% by 2060 (Mather et al., 2019).

The prevalence of certain diseases varies among racial and ethnic groups. Research continues to focus on the potential effects of genetics, genomics, and epigenetics (see Chapter 22), as well as the effects of early individual health behaviors and cultural practices, on the disease patterns of older adults in these various groups. The environment and constructs such as bias; social determinants of health; and **structural racism**, defined as "the combination of institutions, culture, history, ideology, and codified practices that generate and perpetuate inequity among racial and ethnic groups" (American Cancer Society [ACS], 2019, p. 2), play a huge role in the development of health care disparities (CDC, 2021f), which nurses are called to address (American Association of Colleges of Nursing [AACN], 2021). Health disparities that exist between nonminority populations and racial and ethnic minorities are particularly prevalent in the older population. Poverty, the presence of chronic illnesses, and difficulty accessing the health care system make older adults much more vulnerable to a diminished quality of life caused by disease. COVID-19 and the associated pandemic highlighted disparities in the social, economic, and secondary health issues that stemmed from the crisis. Social determinants of health played a role in the exposure, severity of illness, hospitalizations, and deaths associated with the virus (CDC, 2020b). This time was also punctuated by political and social upheaval in response to structural racism and the pronounced access and health disparities.

Profiles of various racial and ethnic groups, as classified by the U.S. government, indicate the following patterns of diseases:

- Heart disease is the leading cause of death for African American men and women. The prevalence of hypertension in Black adults ages 20 years and older in the United States is the highest in the world, with age-adjusted numbers reflecting 58.3% prevalence in non-Hispanic Black males and 57.6% prevalence in non-Hispanic Black females. Hypertension is associated with stroke, heart disease, and other vascular diseases (Virani et al., 2021). African Americans have the highest mortality rate and shortest survival of any minority for most major cancers. Black men have the highest incidence of cancer. Despite lower incidence rates than their non-Hispanic White female counterparts, non-Hispanic Black women have the highest death rates of all racial and ethnic groups for breast and uterine cancer; colorectal and prostate cancers are more common and faster growing (prostate) in Black men than in other racial or ethnic groups (ACS, 2019; CDC, 2013).
- The leading causes of illness and death for Hispanic or Latino Americans are heart disease and cancer. Although Hispanic Americans have lower death rates than non-Hispanic Whites in most areas, they have more deaths from diabetes and chronic liver disease, and a similar number of deaths from kidney disease. Hispanic American adults (ages 20 years and older) have 6.5% more obesity than non-Hispanic Black adults, 12.2% more obesity than non-Hispanic White adults, and 33.1% more obesity than Asian adults. Colorectal screening for adults ages 50 to 75 years shows wide variation based on race and ethnicity: White only 68.2%, Black/African American only 65.2%, Asian only 58.2%, American Indian/Alaska Native only 56%, Hispanic or Latino 57.9%, and Mexican (specifically) 52.5% (CDC, 2021c). It is important to note that Hispanic subgroups have different degrees of risk. For example, Hispanic adults who are of Mexican or Puerto Rican descent are twice as likely to die from diabetes as their White counterparts.
- Asian American individuals comprise many subgroups, with the six largest subgroups (Asian Indian, Chinese, Filipino, Japanese, Korean, and Vietnamese) often considered independently in analyses when reported. Overall, cancer is the leading cause of death for Asian Americans; however, heart disease is the leading cause of death among men of Asian Indian, Filipino, and Japanese descent. Stroke is the overall third leading cause of death (CDC, 2021b). AD mortality increased in Asian Americans, just as it had across all other racial and ethnic groups between 2003 and 2011 (Hastings et al., 2015).
- Heart disease, cancer, unintentional injuries, and diabetes are the leading causes of death in American Indian or Alaska

Native people. Members of the 573 federally recognized tribes and their descendants have lingering heath disparities that result in a life expectancy 5.5 years less than all other races or ethnicities (Indian Health Service, 2019).
- Native Hawaiian or Other Pacific Islanders (from Guam, Samoa, or other islands) generally have higher reported rates of smoking, alcohol consumption, and obesity compared with other ethnic or racial groups. This group shares the leading causes of death with the other groups (i.e., cancer, heart disease, unintentional injuries, stroke, and diabetes), but also has an increase in specific risks and diseases including hepatitis B, HIV/AIDS, and tuberculosis (Office of Minority Health, 2021).

Refer to Chapter 5 for additional discussion of cultural variations and influences on health care.

Accidental Injuries

The older adult is at increased risk for accidental injury because of changes in vision and hearing, loss of mass and strength of muscles, slower reflexes and reaction time, and decreased sensory ability.

Many older adults limit their activities because of their fear of falls that might result in serious health consequences. Falls are the most common cause of injuries and hospital admissions in older adults. More than 25% of older adults fall each year, but less than half tell their health care providers (CDC, 2020a). Fear of falling, personality traits of high neuroticism and low conscientiousness, and indicators of frailty have been shown to contribute to falls in older adults (Bromfield et al., 2017; Canada et al., 2020; Jehu et al., 2021; Makino et al., 2017). Falling once doubles the chance of the older adult falling again. One out of five falls causes serious injury, such as traumatic brain injury (TBI) or a fracture, and over 800,000 patients are hospitalized annually because of fall injuries. More than 95% of hip fractures are caused by falling, typically sideways. When adjusted for inflation, the direct medical costs related to falls average $50 billion annually (CDC, 2020a). Chapters 28 and 34 have additional information regarding the risk for falls and developmental considerations related to ambulation; see also the CDC's fall prevention information, available online at https://www.cdc.gov/homeandrecreationalsafety/falls/adultfalls.html.

In addition to the risk of falls, the combined effects of chronic illness and medications may make an older adult more prone to accidents. Older adults with reduced income may live in inadequate housing in neighborhoods with heavy traffic or high crime rates. They may be isolated from family members, and many live alone. Combined with the normal changes of aging and the effects of any illness, older people not only are at increased risk but also have a more difficult time regaining health after an injury. Refer to the PICOT in Practice display on preventing falls and to Chapter 28 for additional information related to risk for accidental injuries in older adults.

Dementia, Delirium, and Depression

Nurses and the health care team need to be attuned to abnormal processes that may occur in older adults. Often referred to as the "3Ds," dementia, delirium, and depression require specific assessment and management.

DEMENTIA

When a serious mental impairment occurs, the effect on the patient and family can be devastating. The term **dementia** refers to various organic disorders that progressively affect cognitive functioning. Dementia is chronic and usually develops gradually. Many people think of Alzheimer's disease (AD) when dementia is mentioned, but dementia may also occur more suddenly following a stroke or other vascular event. Referred to as *vascular dementia*, this form is often related to hypertension, and is the second most common type of dementia. Other dementias include Lewy body dementia and frontotemporal disorders. Differentiating the specific type of dementia affecting an older adult may be difficult, and many people have a form of *mixed dementia* consisting of two or more types (National Institute on Aging, 2021b).

Of the dementias that affect older adults, **Alzheimer's disease (AD)** is the most common degenerative neurologic illness and the most common cause of cognitive impairment. It is irreversible and progresses from deficits in memory and thinking skills to an eventual inability to perform basic self-care. The first indications of AD usually occur in a person's mid-60s, and nearly half of 85-year-old adults have the disease (National Institute on Aging, 2021b). There are 5.8 million people living with AD today, and this number is expected to more than double to 13.8 million by 2050 (Mather et al., 2019).

Although further research needs to be done to identify potential and actual causes and to find a cure for AD, we now know that the formation of amyloid plaques and tangles of tau proteins have an impact on the brain structure and function in older adults with AD. It is a progressively serious and ultimately fatal disorder. In mild or early AD, forgetfulness and impaired judgment may be evident. Over a period of several years, the person progresses to moderate or middle AD, and becomes progressively more confused, forgetting family and becoming disoriented in familiar surroundings. When the ability to perform simple activities of daily living is lost, and the older adult enters the severe or late stage of AD, the person requires constant supervision and care, often in a long-term care facility. There is no effective medical treatment for AD at this time. Reflect on the Vulnerable Populations Alert on persons with AD and their caregivers.

A common problem in patients with dementia is **sundowning syndrome**, in which an older adult habitually becomes confused, restless, and agitated after dark. Wandering may occur, and coping may be negatively affected by hallucinations, delusions, or paranoia. People with dementia are hospitalized more frequently than other older adults.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

The precipitating factor may be a medical-surgical problem, or the behavioral or psychiatric symptoms that occur with dementia. Often, a medical or nursing intervention can trigger a sequence of adverse events in a frail older adult. This downward spiral and decline is referred to as **cascade iatrogenesis**. Here is an example of cascade iatrogenesis: an episode of confusion and wandering at night may lead to a fall that results in a hip fracture. During the resulting hospitalization, the insertion of an indwelling catheter can precipitate a urinary tract infection that requires use of an antibiotic and possibly the development of antibiotic-resistant organisms. This is, unfortunately, not an uncommon scenario for nurses to encounter.

PICOT in Practice

ASKING CLINICAL QUESTIONS: PREVENTING FRAGILITY HIP FRACTURES

Scenario: You work as a nurse for an organization that offers preventive health care services for residents in a small, rural community. Recently, several 65-year-old and older residents living independently in the community have fallen in their homes. Many of the residents had to be hospitalized for broken hips following their falls. The falls were from low-energy trauma, such as falls from standing height, also known as fragility hip fractures.

As team leader for gerontology services, you want to help reduce the number of hip fractures in older adults in the community and increase bone health. You have read that consumption of dairy products can promote bone health. Other members of the team wonder if certain medications predispose older adults to falls and might be responsible for the risks and rates of falls in the community. You have offered to evaluate the evidence for effectiveness of both of these interventions.

- **Population:** Older adults living independently in the community
- **Intervention:** Dairy consumption
- **Comparison:** Prescribed medication
- **Outcome:** Hip fractures
- **Time:** 12 months

PICOT Question: Among older adults living independently in the community, does consumption of dairy products compared to prescribed medication result in decreased risk of hip fractures over 12 months?

Findings:

1. Hidayat, K., Du, X., Shi, B. M., & Qin, L. Q. (2020). Systematic review and meta-analysis of the association between dairy consumption and the risk of hip fracture: critical interpretation of the currently available evidence. *Osteoporos International*, *31*(8), 1411–1425. https://doi.org/10.1007/s00198-020-05383-3

Nine articles were included in the meta-analysis with a total of 9,564 hip fracture events among 363,383 participants. The evidence from prospective cohort studies reassuringly suggests that the risk of hip fracture may not be elevated among people who consume milk, yogurt, and cheese, and that a greater consumption of milk or yogurt may even be associated with a lower risk of hip fracture depending on the factors that may differ across the population of interest.

2. Mortensen, S. J., Mohamadi, A., Wright, C. L., Chan, J. J., Weaver, M. J., von Keudell, A., & Nazarian, A. (2020). Medications as a risk factor for fragility hip fractures: A systematic review and meta-analysis. *Calcified Tissue International*, *107*(1), 1–9. https://doi.org/10.1007/s00223-020-00688-1

Thirty-eight studies comprising 1,244,155 subjects and 188,966 cases of fragility hip fractures were included in this study. Hormone replacement therapy (HRT) with estrogen was associated with decreased risk of hip fracture. In contrast, the following medications were significantly associated with fragility hip fractures:

- Antidepressants
- Antiparkinsonian drugs
- Antipsychotic drugs
- Anxiolytic drugs
- Benzodiazepines
- Sedatives
- Systemic corticosteroids
- H2 Antagonists
- Proton-pump inhibitors
- Thyroid hormone

Strength of Evidence: Level I systematic reviews

Recommendation: You recommend that the team offer a bone health program that includes information about osteoporosis and fracture prevention. The program targets older adults taking medications associated with higher risk of hip fractures. In addition, the benefits of incorporating dairy products into a healthy, balanced diet are discussed as

well as their unique package of valuable nutrients that are important for bone health.

Vulnerable Population Alert

The 2020 Alzheimer's Disease Facts and Figures

- Alzheimer's disease is the sixth leading cause of death in the United States.
- More than 5 million Americans are living with Alzheimer's disease.
- One in three older adults dies with Alzheimer's disease or another dementia.
- Fifty percent of primary care physicians believe the medical profession is not ready for the growing number of people with dementias.
- Sixteen million Americans provide unpaid care for people with dementias.
- These caregivers provided an estimated 18.6 billion hours valued at nearly $244 billion.
- Between 2000 and 2018, deaths from heart disease have decreased 7.8%, while deaths from Alzheimer's disease have increased 146% (https://www.alz.org/media/Documents/alzheimers-facts-and-figures-infographic.pdf).

Alzheimer's disease takes a devastating toll on caregivers. Compared with caregivers of people without dementia, twice as many caregivers of those with dementia indicate substantial emotional, financial, and physical difficulties. Do you make it a point to talk with the family caregivers of your patients with Alzheimer's disease or other dementias to ask how they are doing?

Caregiver Support Resources

Alzheimer's Association

https://alz.org/help-support/caregiving

Family Caregiver Alliance

https://www.caregiver.org/

For the patient with dementia, communication with family members and a systematic approach to assessment is required. Comprehensive and empathetic nursing care is important. Both the patient and family/caregivers need emotional support and teaching and may benefit from community resources that can ease the family's burden.

DELIRIUM

Sometimes delirium and depression in an older adult are mistaken for true dementia. **Delirium** is an acute syndrome of brain failure that can last from hours to weeks, has a specific cause, and resolves with treatment of the identified underlying cause. Symptoms of delirium include variable deficits in attention, awareness, and cognition that may have hyperactive, hypoactive, or mixed presentations (Thom et al., 2019). Delirium may not have one specific cause, and in older adults may be due to drug interactions, circulatory or metabolic problems, nutritional deficiencies, or a worsening illness that triggers inflammatory processes and disrupts neurotransmitters. During acute illness, older adults are particularly at risk for delirium because of their decreased cognitive reserve (Mattison, 2020; Wan & Chase, 2017).

Prevention is the first step in managing delirium. Incidences of delirium are more likely to occur with six key risk factors: cognitive impairment, sleep deprivation, immobility, visual or hearing impairment, and dehydration (Wan & Chase, 2017). Nurses should focus on these six issues as a starting point for preventive interventions. For example, providing frequent reorientation immediately after surgery serves to reorient and also comfort the patient. Ensuring glasses and hearing aids are at the bedside minimizes the isolation and confusion that may occur when the person awakens from anesthesia in an unfamiliar environment. Medications, such as antipsychotics, are used carefully in delirium because they can inadvertently exacerbate the problem.

When assessing behavioral changes, remember that an older adult with dementia may also develop delirium. This *delirium superimposed on dementia* can be difficult to differentiate. Family members and regular caregivers often serve as the best resources for the identification of a change in the trajectory of dementia in the patient. The focus in this instance is on treating the underlying cause of the delirium and returning the patient to their current (baseline) cognitive function. Key activities include interventions that are person centered, including assessing the patient's baseline cognitive function, integrating the patient's values and interests, enhancing the sensory abilities of the patient to communicate, encouraging the presence of family at the bedside, individualizing cognitive stimulation for that patient, and enhancing behavioral approaches to comfort and sleep (Bellelli et al., 2021; Yevchak et al., 2017).

Box 24-6 lists online resources for assessing for dementia and delirium.

DEPRESSION

Extreme or prolonged sadness in an older adult may be a warning sign of depression. Depression is not a normal part of aging. Death of a spouse or friends, coupled with changes in living environment or financial resources can precipitate feelings of grieving that, if unresolved, may result in depression. There is usually a distinct change of behavior

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

accompanied by other specific signs and symptoms of depression, such as sleep disturbances, weight loss (sometimes gain), difficulty with concentration, irritability or anger, loss of interest in once pleasurable activities, vague pains, crying, fatigue, and suicidal thoughts or preoccupation with death (National Institute on Aging, 2021a).

Box 24-6 Online Tools for Assessment of Delirium and Dementia

Confusion Assessment Method (CAM)

https://help.agscocare.org/table-of-contents/delirium-instruments/H00101
Identifies delirium quickly. Long and short versions are available.

Delirium Observation Screening (DOS) Scale/Delirium Observation Screening Scale (DOSS)

https://deliriumnetwork.org/wp-content/uploads/2018/05/DOSS.pdf
Consists of 13 items focused on routine observation of verbal and nonverbal behaviors.

Mini-Cog

https://mini-cog.com
Two-part test to determine if dementia or cognitive impairment is present (even in early stages). Takes 3 to 5 minutes to administer.

Mini-Mental Status Exam (MMSE)

http://www4.parinc.com/Products/Product.aspx?ProductID=MMSE
The original MMSE contains 30 questions and screens for cognitive impairment, estimates the severity of cognitive impairment, and documents changes over time with respect to decline or response to treatment.

MMSE Second Edition

http://www4.parinc.com/Products/Product.aspx?ProductID=MMSE-2
The second edition may be useful in populations with milder forms of cognitive impairment.

Neecham Confusion Scale

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1852304
Consists of nine items and is used to detect early stages of delirium; does not differentiate between dementia and delirium.

Simple Question for Easy Evaluation of Consciousness (SQEEC) and Single Question in Delirium (SQiD)

https://deliriumnetwork.org/wp-content/uploads/2019/05/SQUEEC.pdf
Two-question (SQiD has one question) screening that requires a narrative reflection.

Depression occurs in 6.3 million older adults worldwide secondary to ageism (World Health Organization, 2021a). Symptoms of depression are often inappropriately attributed to normal aging, drugs, the progression of chronic disease, or cognitive decline. The short form of the Geriatric Depression Scale (GDS), a 15-question screening tool (available online at https://consultgeri.org/try-this/general-assessment/issue-4.pdf), can be used effectively in older adults in any setting. When combined with a mental health assessment by a professional, it can facilitate a diagnosis of depression (Greenberg, 2012). Treatment of depression usually involves psychotherapy or counseling along with antidepressant medication. In an older adult, hopelessness rather than sadness is more often associated with suicidal intent. Depression in older adults varies in its presentation depending on a person's cultural background, stress level, and underlying medical conditions (National Institute on Aging, 2021a). Depression in older adults must be recognized by nurses and treated by the interprofessional team.

Elder Abuse

The increase in the number of older adults coupled with increasing lifespan has resulted in greater awareness about the problem of **elder abuse**, which is defined as, "an intentional act or failure to act by a caregiver or another person in a relationship involving an expectation of trust that causes or creates a risk of harm to an older adult" (Hall et al., 2016, p. 23). Elder abuse is experienced by 1 in 10 community-dwelling, older adults (ages 60 years and older) living in the United States (CDC, 2021a; U.S. Department of Justice, n.d.). An estimated 58% of perpetrators who commit nonfatal assaults against older adults (ages 60 years and older) have a personal relationship (family, friend, acquaintance) with the older adult. Based on the data collected, these cases may meet CDC criteria for elder abuse, which means elder abuse

needs to be recognized as an underreported and widespread public health issue. Compared with women, men have higher rates of death by homicide (increased 7% 2010–2016) and experiencing nonfatal assaults (increased more than 75% 2002–2016), especially among men ages 60 to 69 years (CDC, 2021d; Logan et al., 2019). Environmental, social, financial, educational, and employment-based inequities amplify the risks of experiencing violence across the lifespan, particularly for racial and ethnic minorities. Addressing and reducing health disparities and structural inequities could decrease the violence perpetrated on older adults (Logan et al., 2019). The United States is not alone in managing this global public health priority. Estimates are that 15.7% of older adults (ages 60 years and older) worldwide have experienced some form of abuse (Yon et al., 2017). Worldwide, elder abuse rates have increased during the COVID-19 pandemic. Globally, elder abuse is experienced both in the community (1 in 6) and in long-term care facilities (World Health Organization, 2021b).

Elder abuse includes physical abuse, sexual abuse, psychological or emotional abuse, financial abuse or exploitation, and neglect (Hall et al., 2016).

- *Physical abuse* is the intentional use of physical force that results in acute or chronic illness, physical injury, pain that can range from physical discomfort to agony, functional impairment, distress in the form of mental or physical suffering, or death. Physical abuse includes the inappropriate use of medication, inappropriate use of physical restraints, and physical punishment.
- *Sexual abuse* involves forced or unwanted sexual interaction of any kind with an older adult, including touching and nontouching acts (such as photography, voyeurism, verbal or behavioral sexual harassment, or forced viewing of pornographic materials).
- *Emotional or psychological abuse* includes verbal or nonverbal behavior that results in the caregiver or trusted person inflicting anguish, mental pain, fear, or distress. This type of abuse can include humiliation and disrespect, threats (physical, psychological, or sexual), harassment, and isolation or coercive control.
- *Financial abuse* or *financial exploitation* involves the illegal, improper, or unauthorized use of the resources of an older adult by the caregiver or trusted person for the benefit of someone other than the older adult.
- *Neglect* involves failure by the caregiver or person in a trusted relationship to protect an elder from harm, or failure to meet the need for essential medical care, nutrition and hydration, activities of daily living (hygiene, clothing), or shelter that results in serious risk of compromised health or safety. This risk is considered relative to age, baseline health status, and cultural norms.

Unfortunately, only 1 out of every 23 cases of elder abuse is reported to the appropriate protective services (U.S. Department of Justice, n.d.).

Identification of elder abuse requires an alert health care provider. Indications of abuse are often misinterpreted as normal signs of aging. Careful observation of the relationship between the older adult and the caregiver may be the first evidence that the older adult is a victim of abuse. Pay attention to interactions involving voice tone, caring behaviors, and personal touch. Older adults who have been physically abused present with injuries that are incompatible with the older adult's or caregiver's version of how the injury occurred. Evidence of previously untreated injuries or suspicious cuts and bruises should alert health care providers to the possibility of physical abuse. If you suspect abuse, attempt to speak to the older adult in a private setting away from the caregiver; the suspected abuser should be interviewed only by professionals specifically trained in this type of interview. A victim may deny abuse or choose not to report it because of shame, fear of abandonment, worry about retaliation, or dementia. All assessment data should be objectively documented, including direct quotes from both parties. Most states require that health care professionals report any suspected cases of elder abuse to designated official facilities.

There is a lack of high-quality research studies in the literature, but clinical experience and documented best practice can guide multifaceted screening and intervention (Logan et al., 2019; Moore & Browne, 2016; U.S. Department of Justice, n.d.).

QSEN MULTIDISCIPLINARY TEAMS

The U.S. Department of Justice provides a guide designed to facilitate the development and growth of multidisciplinary teams (MDTs) dedicated to the review of elder abuse cases. This living document is designed to provide a structure for case review that any community can use (available online at https://www.justice.gov/elderjustice/mdt-toolkit).

The International Association of Forensic Nurses (2021) created a nursing curriculum (available at https://www.forensicnurses.org/page/AboutCurriculum) designed to provide nurses with foundational knowledge and skills in basic forensics focused on older adults. Box 24-7 lists various organizations that provide additional information and support about elder abuse.

Older Adults and the Health Care System

Our knowledge of aging has increased dramatically in the past 50 years. **Gerontology** is the scientific and behavioral

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

study of all aspects of aging and its consequences. Normal changes that occur with aging result from complex interactions among genetics, biological systems, and physical and social environments. Disease complicates a person's ability to adapt and maintain **functional health** (the ability to carry out usual and desired daily activities). Mental or physical decline in older adults often may not be directly related to the aging process, but may result from the absence of supportive care and services that could prevent disease and help maintain the older adult's ability to function. The Fulmer SPICES tool (Fulmer, 2019) has proved effective in identifying common problems experienced in older adults that can lead to negative outcomes. It provides information on hospitalized older adults that may assist in preventing and detecting common complications. The acronym SPICES facilitates assessment and information gathering about the following:

Box 24-7 Elder Abuse Resources

Law Enforcement Agencies

Phone: Dial 911
For use when an older adult is in immediate, life-threatening danger or when reporting suspected abuse is mandatory

National Center on Elder Abuse

- **P**—Problems with eating or feeding
- **I**—Incontinence
- **C**—Confusion
- **E**—Evidence of falls
- **S**—Skin breakdown

This instrument can be used in many settings and alerts nurses to quickly identify interventions to individualize an older adult's care.

The increasing aging population has greatly strained a health care system that has traditionally focused on cures and acute disease processes. For an older adult with chronic disorders, the focus of care should include shared goals and promote functional health and independent living to the greatest extent possible. **Gerontologic nursing** combines the basic knowledge and skills of nursing with a specialized knowledge of aging in both illness and health. The terms *geriatrics* and *gerontology* are sometimes used interchangeably. *Geriatrics* is a branch of medicine that focuses on the study of health and disease later in life, while *gerontology* represents the multidisciplinary, scientific study of the effects of aging and age-related diseases on humans. Due in large part to the aging population nurses serve, there has been a shift to include coursework focused on older adults in undergraduate nursing curricula, and to provide postgraduate certifications in gerontology and nurse practitioner tracks focused on geriatrics. Given the increasing numbers of older adults, it is imperative for nurses to address the challenges of an aging population, be competent in geriatric care, integrate developmentally appropriate interventions, and be prepared to make a difference in outcomes for this unique population.

Role of the Nurse in Promoting Health and Preventing Illness

The nurse should teach the older adult patient and family/caregivers general health promotion activities. This is important because older people may consider themselves "too old" to worry about nutrition, exercise, health screenings, and immunizations. In addition to the recommended screenings, examinations, and immunizations outlined in Box 24-2 on page 636, the following should be emphasized:

- Eat a diet that includes all food groups; is low in fat, saturated fat, and cholesterol; balances calories with physical activity; has recommended amounts of fruits, vegetables, and grains; and uses sugar and salt in moderation.
- Make exercise a part of daily activities. This will decrease your risk of falls and may improve your core strength and focus.
- Discuss with your primary provider whether to include nutritional supplements as part of your daily routine. Although

supplementation with vitamins, minerals, and herbs may be beneficial, a provider should guide your supplement plan so that side effects and toxicities are avoided (Eliopoulos, 2022).
- Drink alcohol in moderation.
- Do not smoke.

Box 24-8 **Nursing Actions to Promote Health in Older Adults**

Physiologic Function

- Maintain physiologic reserves. Maintain ongoing assessments for early detection of problems.
- Review perceptions of current health status, health problems, and prescribed or over-the-counter medications.
- Include nursing care that maintains physical status, such as skin care and planned rest and activity.

Cognitive Function

- Slow pace of activity and wait for responses.
- Be sure eyeglasses and hearing aids are used; ensure that lenses are clean and batteries are strong.

Psychosocial Needs

- Be aware that illness, hospitalization, or changes in living arrangements are major stressors.
- Assess and support sources of strength, including cultural and spiritual values and rituals.
- Encourage use of support systems: family (whomever they identify), friends, community resources, and pets.
- Set mutual goals and encourage the patient's role in making decisions about care.
- Encourage life review and reminiscence.
- Encourage self-care.
- Consider the patient's background, interests, capabilities, values, culture, and lifestyle when planning care.

Nutrition

- Assess for lost or damaged teeth; ensure that dentures fit properly. Provide foods appropriate to the patient's ability to chew.
- Assess height, weight, eating patterns, and food choices.
- Assess for malnutrition, especially in older adults impacted by cognitive, psychological, or social factors such as the 3Ds, isolation, limited income or access to nutritious food, and the need for assistance with food preparation or eating (Mangels, 2018).
- Assess swallowing ability.
- Consider using supplements under the direction of a provider.

Sleep and Rest

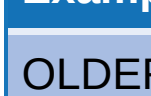
- Discourage excessive napping.
- Assess normal bedtime, time for rising, bedtime rituals, effects of pain, medications, anxiety, and depression.

Elimination

- Assess frequency of bladder elimination as well as problems with incontinence.
- Assess normal times for bowel movements while considering changes in activity, privacy, and medications.
- Ensure that the floor is not cluttered, the toilet is easily accessible, lighting is adequate, and privacy is provided.
- Suggest having safety bars installed in the bathroom.
- Review diet for necessary fluid and fiber content.

Activity and Exercise

- Assess ability to walk; ensure that assistive devices (such as a walker or cane) are available.
- Consider effects of illness, surgery, medications, and changes in diet and fluid intake on strength and motor function.
- Ensure an uncluttered environment with good lighting; suggest using a night light and removing rugs.
- Slow the pace of care, allowing extra time to carry out activities.



for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sexuality

- Assist as necessary with hygiene, hair care, oral care, clean clothing and bedding, makeup, and shaving.
- Maintain a clean, odor-free environment.
- Demonstrate genuine caring: ask preferred name, listen carefully, and respect belongings.
- Discuss sex practices that involve a condom or other barrier device, if appropriate.
- Discuss water-soluble lubricants with females; refer males for evaluation if erectile dysfunction is a concern.

Meeting Developmental Tasks

- Promote continued development and maintenance of functional health by identifying unmet tasks, feelings of isolation, and physical or sensory limitations.
- Assist in finding creative solutions to developmental tasks.
- Collaborate with other health care providers to provide information and referral to community resources for the patient and family.

Concept Mastery Alert

Nurses working with older adults must understand that many changes that are seen are the result of normal interactions and processes of the body. This knowledge is broader than just having knowledge of illness and the older adult.

An older adult who requires surgery or medical treatment for chronic or acute illness has special, age-related needs regardless of the setting for care. Nursing care to meet age-related and developmental needs in any setting is outlined in Box 24-8. Although nursing care adapted to the needs of older adults is described throughout this text, general principles for care are included here. Nurses must recognize physiologic and psychosocial interrelationships and view older adults holistically. See the accompanying display, Examples of Actual or Potential Health Problems and Needs: Older Adult on page 656.

Illness can severely disrupt an older adult's ability to function independently. The ill patient is under increased physical and emotional stress, which increases the risk for complications because of the lack of physiologic reserves. When a patient is hospitalized or institutionalized, family and community interactions are severely inhibited. The acute care environment itself adds new stressors such as diagnostic tests, treatments, and surgery. In the face of new and unfamiliar routines and sensory stimulation, prior coping skills may not work, and an older adult may feel less able to understand and control the new environment. An older adult is more likely than a younger patient to suffer multisystem dysfunctions, iatrogenic complications (caused by medications or treatments), delirium, increasing dependence with changes in their baseline, and accidents such as falls. Hospitalization of an older adult can also substantially accelerate cognitive decline.

Examples of Actual or Potential Health Problems and Needs

OLDER ADULT

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Impaired Older Adult Development	• Inability to maintain or establish ties with friends, family, and acquaintances • Difficulty finding a place in life • Comorbidities affecting daily functional ability • Lack of control over finances, living situation, or other required resources	• Disturbed sleep pattern • Disengagement from activities and people • Frequent ED visits or hospitalizations • Focus on deficits and effects of aging • Difficulty making required role transitions
Injury Risk	• Inadequate intake or poor nutritional value of food • Community immunization level • Community resource deficit or lack of ability to access existing sources of support	—

	• Unsafe or abusive living situation • Social isolation secondary to transportation, social, financial, or community issues	
Readiness for Effective Spiritual Status	—	• Articulates contentment with status and life • Exhibits gerotranscendence • Has a sustained purpose in life • Adapts to expected and unexpected changes associated with aging and loss • Identifies sources of support, resources in the community, and mutually beneficial interactions with others

Source: International Council of Nurses (ICN). (2019). *Nursing diagnosis and outcome statements*. https://www.icn.ch/sites/default/files/inline-files/ICNP2019-DC.pdf; Wolters Kluwer. (2022). *Problem-based care plans*. In Lippincott Advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

The focus of nursing care is to assist older adults to function as independently as possible and to support their individual strengths. The nurse collaborates with the family and other members of the caregiving team to prevent complications of illness, to secure a safe and comfortable environment, and to promote the patient's return to health.

CARING FOR AN AGING POPULATION

Medical advances have enabled older adult and frail patients with serious and chronic illnesses and disabilities to survive much longer than they could in the past. American society faces the dilemma of how to care for this population. Already, millions of American families are struggling nobly to provide steady and demanding long-term care for their incapacitated loved ones, often with little respite or communal support, and usually for many years. It seems unlikely that increasing paid caregiving will be able to alleviate the growing strains on family caregivers. The pool of workers available for paid home health care is shrinking. Factors reducing the number of home health aides and nurses include the strenuousness of the work involved, inadequate financial compensation, difficult relationships with patients, language and cultural barriers, an aging nursing workforce, and the lack of health insurance and other benefits. Caring for older adults is complicated, but rewarding. The challenge for nurses is to incorporate the patient and family into the team and then work to identify, implement, and evaluate strategies to promote health and diminish or postpone frailty in this older population.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Complete the following sentences, then analyze the reasons for your answers:

a. When my parents can no longer care for themselves, I will _____.

b. If my parents were living in a long-term care facility, I would want the nurses to _____.

c. When I am old, I want my family to _____.

. Consider your own family. Can you identify developmental tasks for family members who are middle-aged adults and older adults? What factors in your family facilitate or impede meeting these tasks?

PRACTICING FOR NCLEX

. A nurse caring for older adults in a provider's office researches aging theories to help determine why some people age more rapidly than others. Which statements describe the immunity theory of the aging process? Select all that apply.

a. Immunosenescence likely promotes the increase in infections in the older adult.

b. Free radicals have adverse effects on adjacent molecules.

c. Decreases in size and function of the thymus result in more infections.

d. Nutrition likely plays an important role in maintaining the immune response.

e. Lifespan depends to a great extent on genetic factors.

f. Organisms wear out from increased metabolic functioning.

. A nursing student caring for older adults in a skilled nursing facility is completing an assignment identifying physical

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

changes that are part of normal aging. What changes will the student include in this assignment? Select all that apply.

a. Fatty tissue is redistributed.
b. Skin is drier and wrinkles appear.
c. Cardiac output increases.
d. Muscle mass increases.
e. Hormone production increases.
f. Visual and hearing acuity diminishes.

. A nurse researcher interviews adults to validate Erikson's theory that middle-aged adults who do not achieve their developmental tasks may be in the stage of stagnation. Which patient statement will the nurse correlate to this theory?

a. "I am helping my parents move into an assisted-living facility."
b. "I spend all of my time going to the doctor to be sure I am not sick."
c. "I have enough money to help my son and his wife when they need it."
d. "I earned this gray hair and I like it!"

. A nurse providing health services for a community setting for people age 55 years and older considers health problems for these residents. Which of the following problems is most appropriate for many middle-aged adults?

a. Adequate nutrition
b. Mental health problems
c. Abuse
d. Caregiver role strain

. The charge nurse in a long-term care facility discusses ageism with new nurse employees. Nurses are asked to intervene if they observe which of these examples demonstrating ageism?

a. The AP encourages older adults to apply makeup or aftershave to promote positive self-image.
b. The activity director explains to an older adult they could learn to use video conferencing to speak to their grandchildren.
c. A nurse colleague states that older adult should not think about having a boyfriend or girlfriend after age 70 years.
d. A nurse recognizes the patient who lost their partner of 45 years may be experiencing loneliness.

. A nurse is caring for older adults in a senior adult day services (ADS) center. Which findings require follow up with the health care provider?

a. Skin pigmentation caused by exposure to sun over the years
b. Thin toenails with a bluish tint to the nail beds
c. Using a walker while healing from a hip fracture related to brittle bones
d. Bruising on forearms due to fragile blood vessels in the dermis

. A nursing instructor teaching a gerontology class to nursing students discusses myths related to the aging of adults. Which statement will the students identify as a myth about older adults?

a. Most older adults live in their own homes.
b. Healthy older adults enjoy sexual activity.
c. Aging results in mental deterioration.
d. Older adults want to be attractive to others.

. A nurse is helping to prepare a calendar for an older adult patient with cognitive impairment. Which type of cognitive impairment is non-reversible?

a. Post-stroke speech issues
b. Malnutrition
c. Alzheimer's disease
d. Loss of cardiac reserve

. A nurse caring for an older adult living in a long-term care facility uses reminiscence to help the patient adapt to the changes of aging. The nurse uses which question to encourage reminiscence?

a. "Tell me about how you celebrated Christmas when you were young."
b. "Tell me how you plan to spend your time this weekend."
c. "Did you enjoy the choral group that performed here yesterday?
d. "Why don't you want to talk about your feelings?"

. Following a fall that left an older adult temporarily bedridden, the nurse is using the SPICES assessment tool to evaluate for cascade iatrogenesis. Which are correct aspects of this tool? Select all that apply.

a. S—Senility

b. P—Problems with feeding
c. I—Irritability
d. C—Confusion
e. E—Edema of the legs
f. S—Skin breakdown

. The nurse in a long-term care facility states in report that an older adult resident is quite frail. The oncoming caregiver prioritizes prevention of what problem?
a. Confusion
b. Falls
c. Delirium
d. Dementia

. A patient is admitted to the acute care medical center with change in mental status, dehydration, and electrolyte imbalances. Which of these reflects a reversible cause of the changes in mental status?
a. Alzheimer's disease
b. Delirium
c. Dementia
d. Delirium superimposed on dementia

ANSWERS WITH RATIONALES

. **a, c, d.** The immunity theory of aging focuses on the functions of the immune system and states that the immune response declines steadily after younger adulthood as the thymus loses size and function, resulting in more infections. Vitamin supplements (such as vitamin E) may improve immune function. The cross-linkage theory proposed that a chemical reaction produces damage to the DNA and cell death. The free radical theory states that free radicals—molecules with separated high-energy electrons—formed during cellular metabolism can have adverse effects on adjacent molecules. The genetic theory of aging holds that lifespan depends to a great extent on genetic factors. According to the wear-and-tear theory, organisms wear out from increased metabolic functioning, and cells become exhausted from continual energy depletion from adapting to stressors.

. **a, b, f.** Physical changes occurring with aging include these: fatty tissue is redistributed, the skin is drier and wrinkles appear, and visual and hearing acuity diminishes. Cardiac output decreases, muscle mass decreases (sarcopenia), and hormone production decreases, causing menopause or andropause.

. **b.** According to Erikson (1963), the middle adult is in a period of generativity versus stagnation. The tasks are to establish and guide the next generation, accept middle-age changes, adjust to the needs of aging parents, and reevaluate goals and accomplishments. Middle adults who do not reach generativity tend to become overly concerned about their own physical and emotional health needs.

. **d.** Many middle-aged adults help care for aging parents and have concerns about their own health and ability to continue to care for an older family member. Caregivers often face 24-hour care responsibilities for extended periods of time, which creates physical and emotional problems for the caregiver. Nutritional issues are more common in the childhood years and possibly in older adults. Mental health issues and abuse can occur in multiple age groups.

. **c.** *Ageism* is a form of prejudice in which older adults are stereotyped by characteristics found in only some of their age group. The other statements are positive, building on the older adults' strengths and resilience.

. **b.** Older adults' toenails may become thicker (not thinner), with a yellowish tint (not a bluish tint) to the nail beds; a blue tint may indicate hypoxemia. Exposure to sun over the years can cause older adults' skin to be pigmented. Bone demineralization occurs with aging, causing bones to become porous and brittle, making fractures more common. The blood vessels in the dermis become more fragile, causing an increase in bruising and purpura.

. **c.** Although response time may be longer, intelligence does not normally decrease because of aging. Most older adults live in their own homes. Although sexual activity may be less frequent, the ability to perform and enjoy sexual activity lasts well into the 90s in healthy older adults. Older adults want to be attractive to others.

. **c.** Alzheimer's disease causes progressive, irreversible cognitive impairment. It is the most common degenerative neurologic illness and the most common cause of cognitive impairment. With therapeutic intervention, speech therapy, proper diet, and pharmacologic intervention, the other problems can be managed and potentially improved.

. **a.** Use of life review or reminiscence encourages reflection; the older adult can restructure life experiences and better adapt to life circumstances. Asking about a recent event, upcoming plans, or feelings would be unlikely to encourage reminiscence.

. **b, d, f.** The SPICES acronym is used to identify common problems in older adults and stands for:
S—Sleep disorders
P—Problems with eating or feeding

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

I—Incontinence
C—Confusion
E—Evidence of falls
S—Skin breakdown

. **b.** Fear of falling, indicators of frailty, and personality traits of high neuroticism and low conscientiousness contribute to falls in older adults. Falling once doubles the chance of the older adult falling again.

. **b.** Delirium, an acute syndrome of brain failure, can last from hours to weeks, has a specific cause, and resolves with treatment of the identified underlying cause. Symptoms of delirium include deficits in attention, awareness, and cognition. Dementia refers to various organic disorders affecting cognitive function that are progressive and irreversible.

UNIT V Actions Basic to Nursing Care

Unit V focuses on the actions basic to practice—the nursing interventions planned, implemented, and evaluated to meet the health care needs of diverse patients across the lifespan, at any point along the health–illness continuum, and in all settings. Nursing interventions discussed in this unit include reducing and preventing transmission of pathogens, assessing vital signs, conducting a health history and physical assessment, maintaining safety, integrating complementary health approaches and integrative health concepts, administering medications, and providing perioperative care.

Chapter 25 explains medical and surgical aseptic techniques necessary to prevent and control the spread of microorganisms. Chapter 26 describes assessing vital signs, and Chapter 27 discusses conducting a health history and physical assessment. Nursing assessment is both an art and a science. The art of performing a skill is integrated into the science of nursing so that variations from normal are identified and evaluated, and necessary nursing interventions are implemented. The findings from assessments provide a database necessary to maintain or restore health and promote wellness.

Nurses are responsible for meeting basic human needs for physical safety and security. Chapter 28 discusses promoting environmental safety (including threats from bioterrorism), identifying risk factors for patients at any age, and implementing teaching and other nursing actions to prevent accidents. Chapter 29 discusses complementary health approaches and integrative health concepts, an ever-increasing component of health care.

Chapters 30 and 31 focus on collaborative and independent nursing interventions used to accurately and safely administer medications and provide perioperative care. In most instances, the advanced-practice professional prescribes the medications, and the surgeon performs the surgery. The nurse implements nursing interventions to promote patient safety and knowledge, and to facilitate optimal function or recovery in both hospital and community settings. Although facility procedures and protocols are often used in these situations, nursing interventions are individualized to the unique needs of each person requiring care.

“Our intent when we lay hands on the patient in bodily care is to comfort.”

Lydia Hall (1906–1969), *an innovator in nursing practice, developed the theory that the direct nurse-to-patient relationship is itself therapeutic and that nursing care is the chief therapy for critically ill patients.*

25

Asepsis and Infection Control

Jackson Ray Ivers

Jackson Ray comes to visit his mother, who has been hospitalized for a new-onset fever and cough after exposure to a friend with a highly communicable respiratory virus. He notices a sign on the door to check at the nurse's desk before entering. He asks, "What's going on? Why do I have to wash my hands and wear a mask?"

Esther Bailey

Esther, a 72-year-old patient has developed a postoperative wound infection after abdominal surgery. She also demonstrates new-onset, postoperative urinary retention and an inability to void. The standard of care in this situation requires insertion of an indwelling urinary catheter.

Giselle Turheis

Giselle, a 38-year-old woman undergoing chemotherapy treatment for leukemia, states, "I know that my risk for infection is really high because of my poor immune status. But how do I respond to my Sunday school students, who are used to greeting me with a big hug? I want to be safe, but I know that I need

these hugs too!”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Explain the infection cycle.
. List the stages of an infection.
. Identify patients at risk for developing an infection.
. Describe nursing interventions used to break the chain of infection.
. Identify situations in which hand hygiene is indicated.
. Identify multidrug-resistant organisms that are prevalent in hospitalized patients and community settings.
. List actual and potential problems and needs for a patient who has or is at risk for infection.
. Describe strategies for implementing CDC guidelines for standard and transmission-based precautions when caring for patients.
. Implement recommended techniques for medical and surgical asepsis.

virus

A major concern for health care providers is the danger of spreading microorganisms from person to person and from place to place. Microorganisms are naturally present in almost all environments. Not all microorganisms are harmful—it depends on the type of organism, its location, the **host** (living being where an infectious, parasitic, or pathogenic agent resides and receives sustenance), and the circumstances. The Centers for Disease Prevention and Control (CDC, 2019g) defines **antimicrobials** as "drugs that treat infections by killing or slowing the growth of microbes causing infection …. bacterial infections are treated with drugs called antibiotics" (p. 7). Although *antimicrobial* and *antibiotic* are occasionally used interchangeably, antimicrobials technically include antifungals and drugs that treat parasites and viruses.

Government facilities at the international, national, state, and local levels, health care personnel, and laypeople recognize the need for an organized, systematic approach to the control of infections. For example, the CDC is the US government facility responsible for investigating, preventing, and controlling disease. Efforts by these facilities and people include mass immunization programs, laws concerning safe sewage disposal, regulations for the control of communicable diseases, and hospital infection–surveillance programs. Medical science continues to grapple with problems caused by increasingly virulent organisms that have become drug resistant, and problems related to patients who are vulnerable, including those who are immunologically compromised.

Prevention of infection is a major focus for nurses. The Quality and Safety Education for Nurses (QSEN Institute, 2020) initiative has identified safety as one of the leading issues in health care. The focus on safety includes effective infection control practices. As primary caregivers, nurses are involved in identifying, preventing, controlling, and teaching the patient about infection (see the accompanying Reflective Practice box on page 664). Applying infection prevention and control principles is the first critical step in breaking the cycle of infection.

INFECTION

Infection Cycle

An **infection** is a disease state that results from the presence of **pathogens** (disease-producing microorganisms) in or on the body. An infection occurs as a result of a cyclic process, consisting of six components, as shown in Figure 25-1 (on page 665). These components are:

- Infectious agent
- Reservoir
- Portal of exit
- Means of transmission
- Portals of entry
- Susceptible host

Infectious Agent

Some of the more prevalent agents that cause infection are bacteria, viruses, and fungi. **Bacteria**, the most significant and most commonly observed infection-causing agents in health care institutions, can be categorized in various ways. They are categorized by shape: spherical (cocci), rod shaped (bacilli), or corkscrew shaped (spirochetes). Bacteria can be categorized as either gram positive or gram negative based on their reaction to the Gram stain. For example, gram-positive bacteria have a thick cell wall that resists decolorization (loss of color) and are stained violet. However, gram-negative bacteria have chemically more complex cell walls and can be decolorized by alcohol. Thus, gram-negative bacteria do not stain. This information is crucial for providers when prescribing the most appropriate antibiotic therapy because antibiotics are classified as specifically effective against only gram-positive organisms or as broad spectrum and effective against several groups of microorganisms. Another distinguishing characteristic of (or way of categorizing) bacteria is their need for oxygen. Most bacteria require oxygen to live and grow and are, therefore, referred to as **aerobic**. Those that can live without oxygen are **anaerobic** bacteria.

A **virus** is the smallest of all microorganisms, visible only with an electron microscope. Viruses cause many infections, including the common cold, hepatitis A, B, and C (Centers for Disease Control and Prevention [CDC], 2020d), and human immunodeficiency virus (HIV). Antibiotics have no effect on viruses. However, there are some antiviral medications that decrease the severity and duration of viral infections such as influenza. The exact antiviral prescribed varies depending on the strain of influenza most prevalent in a given season and does not replace annual immunization (*flu shot*; CDC, 2019b). When given in the prodromal stage (infection/disease has begun, but the symptoms are just beginning and may be vague), antivirals can shorten the course of the illness with certain viruses such as herpes simplex virus type 1 (HSV-1; cold sores). With HIV specifically, antiretroviral therapy (ART) regimens are initiated as soon as possible after diagnosis because they effectively disturb the life cycle of the virus to block HIV replication and, ultimately, render the virus undetectable (Saag, 2019).

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

This is my last clinical rotation before graduation, and it has been a difficult year. My focus has been somewhat lacking for a while, and I haven't been as prepared as I should have been for my clinical and classroom experiences. My clinical instructor has been on my case for the last few weeks. I'm also realizing that in no time at all I will be out of school and providing patient care on my own. So, all of a sudden, I'm eager for as many clinical experiences as I can get. To make a long story short, I'm thrilled when offered the opportunity to catheterize Esther Bailey, a 72-year-old female patient on my unit. I quickly review the procedure and go to the patient's room, with the catheterization supplies in hand, feeling semi-confident. After introducing my clinical instructor and myself, and explaining what I'm about to do, I open the sterile package, prepare the sterile field, and cleanse the meatus. All of a sudden, as the patient asks a question and diverts my instructor's gaze, I realize (to my horror!) that I've contaminated the catheter. I've got a split second to decide what to do. I can tell my instructor what happened, obtain a new kit, and proceed anew, or pretend nothing happened and continue. After everything that has been drilled into us about the importance of sterility and the consequences of health care–associated infections (HAIs), I don't like that I'm even considering not admitting the mistake. But I'm also aware that it is time to leave the unit and the rest of the group is waiting for post-conference. Plus, after all, there are financial costs to obtaining another tray. But what if I do not admit the error and the instructor did see me contaminate the catheter? I run the risk of violating our university honor code!

Thinking Outside the Box: Possible Courses of Action

- Obviously the simplest solution: admit my error and accept the consequences.
- Request a new catheter and inform my instructor later that the patient moved just as I was preparing to enter the meatus (a bit of deception but this makes the error not MY fault).
- Alternatively, pretend that nothing happened and pray that no harm comes to the patient. (After all, how much bacteria do you need to contaminate a catheter? The patient is receiving antibiotic therapy postoperatively anyway.)
- Continue and not even be bothered by the contamination. (Life is one big risk for everyone, right? All that matters is that you take care of yourself first.)

Evaluating a Good Outcome: How Do I Define Success?

- Patient benefited from my actions or, at the very least, was not harmed.
- No one's integrity is compromised or sacrificed.
- No violations of the standards of practice or our nursing code of ethics (American Nurses Association [ANA], 2015) occurred.

Personal Learning: Here's to the Future!

At least I can say there was a happy ending to this story. I did stop, explain what happened, and waited while someone ran for a new catheterization tray. Amazingly, my instructor told me later that she valued my maturity, honesty, and ability to put the needs of the patient ahead of my own needs, stating that I "might just have what it takes after all!" I'm not sure how often I'll be called upon to put the needs of a patient ahead of my own needs, but hopefully I'll be ready to respond selflessly each time.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

How do you think you would respond in a similar situation? Why? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety when caring for patients like Mrs. Bailey?

Patient-Centered Care: What information regarding this procedure needs to be communicated to the patient? Does Mrs. Bailey understand why the urinary catheter is being inserted and the preferred target time for its removal?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to provide clear, comprehensive information to Mrs. Bailey? Did you explain to Mrs. Bailey why there was a pause in the procedure? Was your request for the additional supplies clearly and respectfully communicated to a team member? How was the charge/billing for the additional supplies handled?

Safety/Evidence-Based Practice: Is there anything you could have done to anticipate the unexpected? How do you think your response affected the situation? What evidence in nursing literature provides guidance for decision making regarding infection control?

Informatics: Can you identify the essential information that must be available in Mrs. Bailey's electronic record to support safe patient care? Is it important to electronically document daily the reasons why the urinary catheter is still in place?

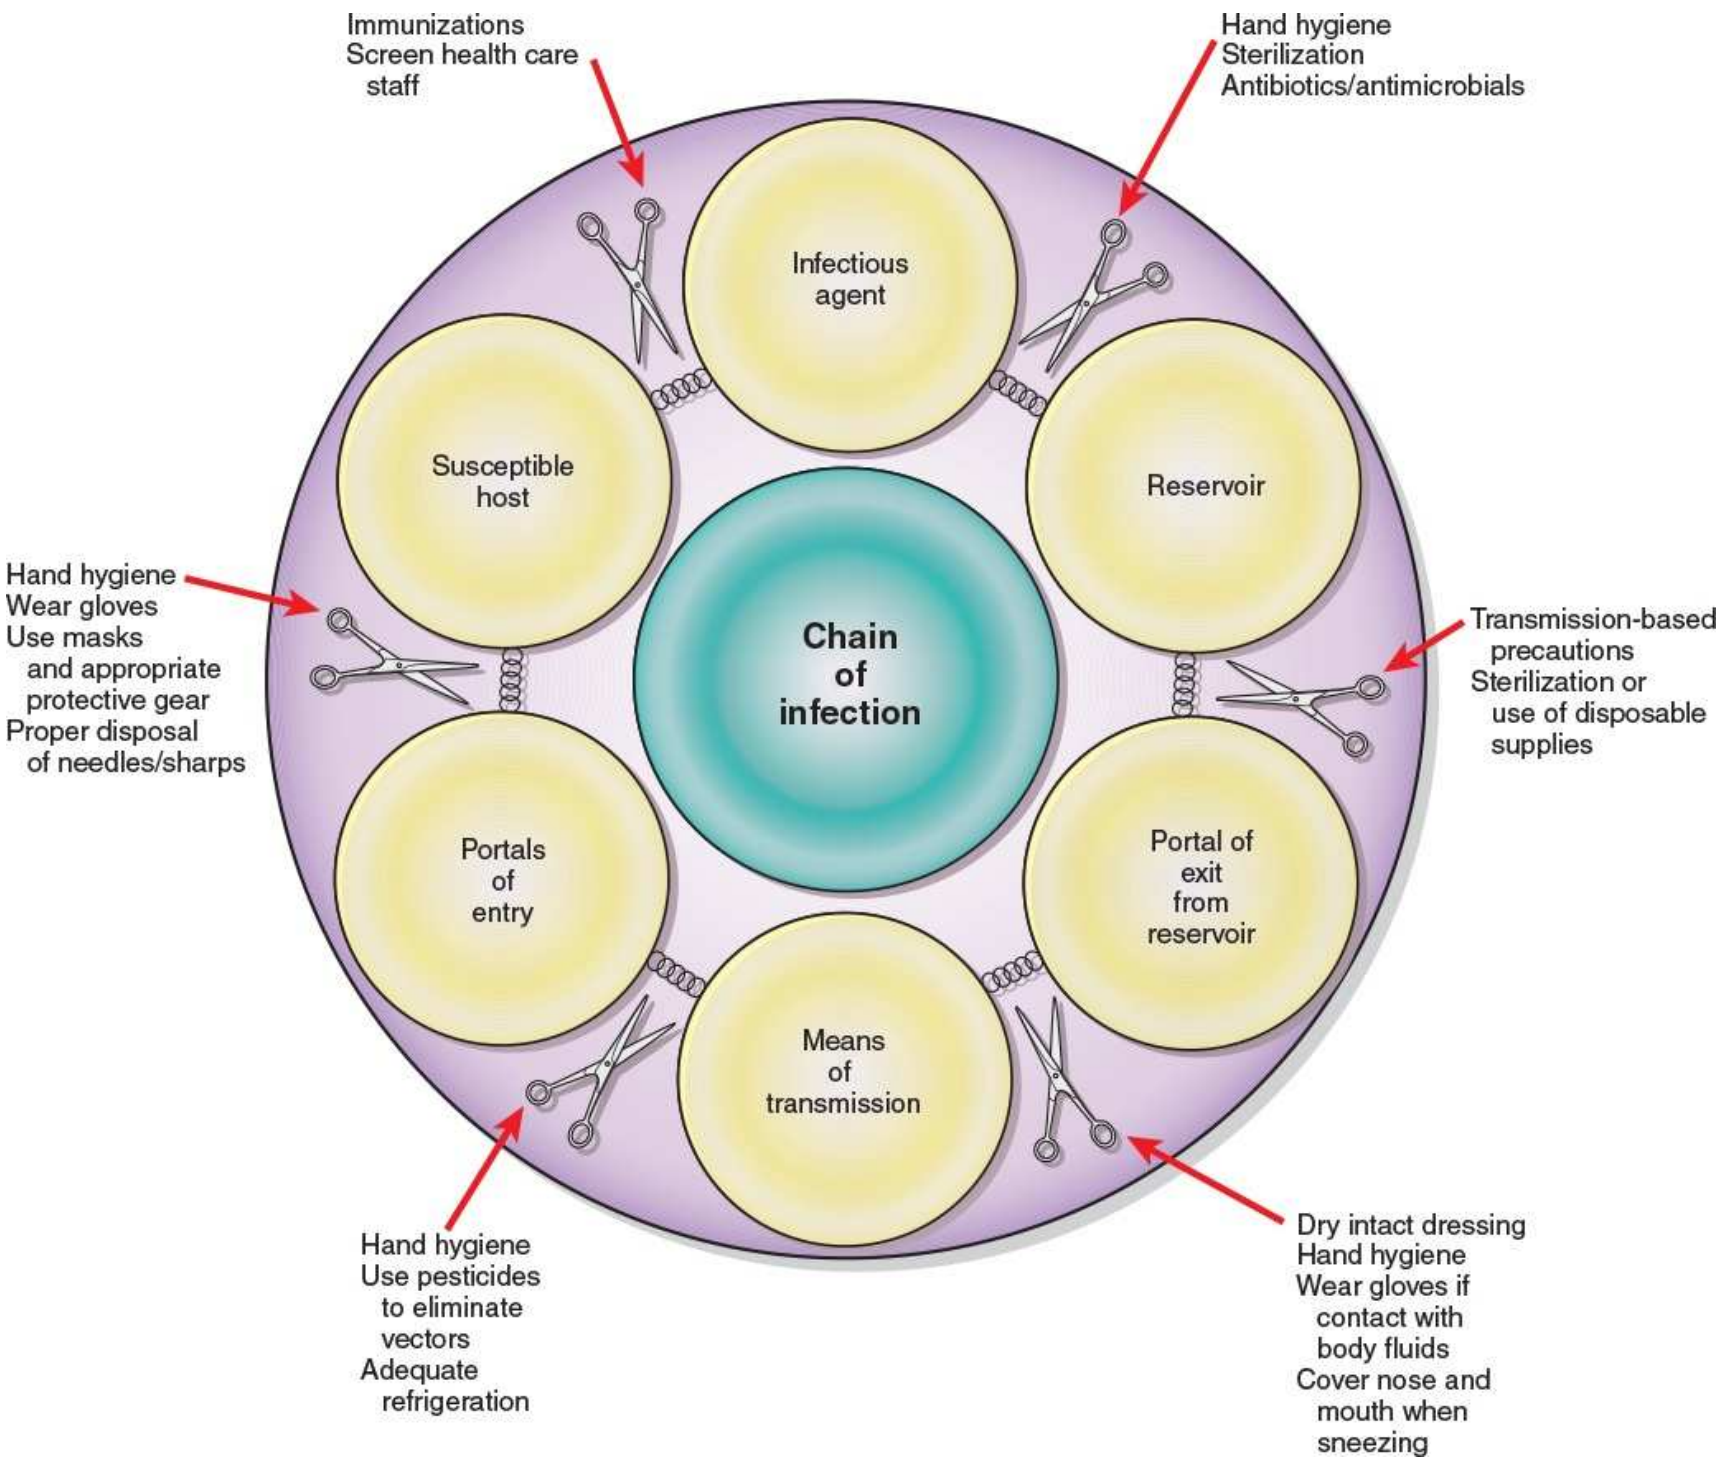

FIGURE 25-1. The infection cycle is demonstrated as a chain. The goal is to break the links of the chain to end the cycle. (*Source:* Adapted from Murphy, D. [1998]. Infectious microbes and disease: General principles. *Nursing Spectrum*, *7*[2], 12–14.)

Fungi, plantlike organisms (molds and yeasts) that also can cause infection, are present in the air, soil, and water. Some examples of infections caused by fungi include athlete's foot, ringworm, and yeast infections. These infections are treated with antifungal medications; however, many infections due to fungi are resistant to treatment. **Parasites** are organisms that live on or in a host and rely on it for nourishment. Malaria is a serious disease that occurs when a parasite infects a certain type of mosquito that then feeds on humans.

Not all organisms to which a person is exposed cause disease. An organism's potential to produce disease in a person depends on a variety of factors, including:

- Number of organisms
- **Virulence** of the organism, or its ability to cause disease
- Competence of the person's immune system
- Length and intimacy (extent) of the contact between the person and the microorganism

IDENTIFICATION OF INFECTIOUS AGENTS

Identifying the type of infection and infectious agent is not always an easy process. Sometimes new diseases appear, and health care workers race to identify them so that treatment can begin. This is the process that occurred with AIDS and with severe acute respiratory syndrome (SARS). Other times, a disease that is **endemic** (occurs with predictability in one specific region or population) can appear in a different geographic location. For example, malaria that is endemic in Africa, particularly south of the Sahara and in parts of Oceania, is tracked to allow for ongoing assessment of the malaria situation around the world (CDC, 2020f). In cases like these, countries collaborate to learn about and implement diagnostic, control, and treatment options (World Health Organization [WHO], 2020b). **Pandemics**, like the one experienced with novel coronavirus (SARS-CoV-2) and the disease it causes (COVID-19) starting in 2019, are global outbreaks of a novel (new or not previously identified) virus that did not initially not have a known immunization or treatment (National Institute of Allergy and Infectious Disease, 2020). See the Challenging Topics feature.

Thoughtful Person-Centered Practice: Challenging Topics

Pandemic Considerations

Nursing is a profession. Among the hallmarks of professions are a certain degree of altruism and the quality of being self-regulating. When the coronavirus presented globally and in the United States in 2020, nurses were understandably on the frontlines of caring for the public. They cared for those who had contracted the virus, those at high risk of contracting the virus, and those who had exposure to persons with COVID-19. The ANA *Code of Ethics for Nurses* instructs nurses that our primary commitment is to patients, while at the same time telling us we have duties to self. Balancing these primary commitments during the pandemic became particularly stressful for many nurses and other health care professionals.

Reflection-in-Action

As you read, think about what the nurse needs to consider, both personally and professionally. What were the nurse's original thoughts? What factors were weighed in the decision making process? How did the nurse prioritize personal and professional responsibilities?

Scenario

Carol, a critical care nurse practitioner with three children, one of whom is a newborn, got a call to come back to work early. She had 3 weeks of maternity leave remaining, but a coworker was self-quarantining after feeling sick and getting tested, and the practice was short-staffed. Carol's husband was an emergency room physician already working extra shifts. If she went back to work, she had to think about how to stay safe (she knew about the shortage of personal protective equipment [PPE], N95 masks, gowns, etc.) and how to arrange care for her children. Her oldest was age 4 years. Her mother, age 65 years, was going to help, but this was now too risky given her mother's history of lung disease. Her mother's age and chronic condition put her in the highest-risk category.

Effective Noticing (Cues)

1. What did you notice about the situation initially? What information/observations are significant? What makes this situation different from a regular work assignment?

Effective Interpreting

2. How would you describe the obligations Carol has to "the patients who need her," her employer and team members, her family, herself, others?
3. If she cannot fulfill each of these obligations, how should she prioritize them? What basis/rationale would you use for prioritization?

Scenario

Remember that the ANA *Code of Ethics for Nurse*s reminds us that "the nurse's primary commitment is to the patient," while at the same time states that "the nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth. In order to calculate her risk Carol needs to know more about the coronavirus and COVID-19. She also needs to know how to stay safe at work.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Effective Responding

4. Where is the best place to turn for guidelines? What resources should she tap?
5. If Carol believes that her hospital lacks the PPE to keep her safe, how should she respond? Does this lessen her obligation to work for this employer?

Scenario

Carol and her husband debated the pros and cons of her returning to work. After careful consideration, Carol, in partnership with her husband, made the anguished decision to return to work. “I know my patients need me.” She would put whatever safeguards were needed to protect her family and loved ones, but she was called to care for her patients in this hugely uncertain time of need. In times of crisis, resource scarcity and the associated intentional allocation may become a serious consideration. The weight of a prolonged pandemic also affects individual and collective decision making and tolerance of risk.

Effective Reflecting

6. Do you agree with the choice the nurse made? Would you have made the same choice, why or why not? What would inform your decision?
7. How do you evaluate your professional and moral judgments?
8. Whether or not you decide to go back to work early, how might you use reflective practice to evaluate your decision so you can respond more confidently in the future? What criteria will you use to evaluate a good response? What personal characteristics inform your practice?
9. How would you respond to having to deny critical care to your oldest and sickest patients who would be least likely to benefit from scarce equipment and resources?
10. How do we handle exemptions to vaccine mandates? When do individual beliefs and practices take precedence over public health measures?

Reflection-on-Action

Then look back at the nurse’s decisions and reflect on your learning—how did your knowledge and/or skills expand based on this scenario? What attitude, value, or belief shifts did you experience (if any) after reading this scenario? What would you do differently if you were in this situation? What more do you need to know to be able to manage this or a similar situation in the future?

Here is ethics guidance for health care institutions (https://www.thehastingscenter.org/ethicalframeworkcovid19/) and a resource hub on ethical issues in pandemics (https://www.thehastingscenter.org/publications-resources/ethics-resources-on-the-coronavirus/).

COLONIZATION VERSUS INFECTION

Under normal conditions, some organisms may not produce disease. Microorganisms that commonly inhabit various body sites and are part of the body’s natural defense system are referred to as normal flora. However, in certain situations, a typically harmless organism may generate an infection, especially in susceptible people. These bacteria are referred to as opportunists. For example, one type of *Escherichia coli* (*E. coli*) normally resides in the intestinal tract and causes no harm. However, if it migrates to the urinary tract, it can lead to urinary tract infection (UTI). Another example is the *Clostridioides difficile* organism (*C. diff*; formerly known as *Clostridium difficile*). If the *C. diff* organism resides in a person’s body, but there are no clinical signs of an infection, this is referred to as *C. diff* **colonization**. An infection is present once the person exhibits specific manifestations of the disease. With both *E. coli* and *C. diff*, microscopic examinations reveal the presence of the bacteria. If a person’s defense mechanisms are ineffective in responding to the bacterial invasion (colonization), infection will result.

Reservoir

The **reservoir** for growth and multiplication of microorganisms is the natural habitat of the organism. Possible reservoirs that support organisms pathogenic to humans include other people, animals, soil, food, water, milk, and inanimate objects.

OTHER PEOPLE

Some people who act as reservoirs for an infectious agent demonstrate signs and symptoms of the disease. Other people act as reservoirs for the infectious agent, but do not exhibit any manifestations of the disease. These people are considered carriers. Carriers, although asymptomatic, can transmit the disease. For example, a person who has tested positive for the HIV antibody/antigen may not exhibit any signs and symptoms of the disease at the time of testing. However, even the asymptomatic person may transmit the virus to others by activities such as condomless intimate sexual contact or sharing a contaminated needle and syringe. An infected pregnant woman may transmit the virus to her child during pregnancy, birth, or breastfeeding.

OTHER RESERVOIRS

Many other reservoirs exist and are encountered on a daily basis. The rabies virus is an example of a pathogen whose reservoir is various animals, notably dogs, squirrels, bats, and raccoons. A person contracts the rabies virus when bitten by an infected animal. The West Nile virus (WNV) is an example of an arbovirus (transmitted between arthropod [insect] vectors and a vertebrate host) whose reservoir is usually an infected mosquito or tick (McDonald et al., 2019). Mosquitoes feed on infected birds, become infected, and pass the infection on to people when feeding on their blood. The first local transmission of Zika virus infection was reported in December 2015 in the Caribbean. Zika is also transmitted by mosquitoes, which means that methods to prevent transmission of WNV (primarily prevention of mosquito bites) apply to Zika virus as well. Sexual and maternal–fetal transmission of Zika virus have been documented; poor pregnancy outcomes and microcephaly (a brain defect) can occur (CDC, 2020e), so preconception counseling is recommended (Polen et al., 2018).

Water can harbor *Giardia, E. coli* 0157-H7, and *Shigella.* Drinking or swimming in contaminated water can begin the infectious cycle in a person. Soil can act as a reservoir for the organisms that cause gas gangrene and tetanus. Food can also be a reservoir. Undercooked ground beef and fresh leafy vegetables have been identified as responsible for recent outbreaks of *E. coli* infections. The CDC recommends that all ground beef be cooked until well done and new laws keep fruits and vegetables safer when they are grown, picked, and washed. Milk can contain *Listeria* unless it is pasteurized. Reporting infectious disease outbreaks, including domestic foodborne illnesses with their associated recalls (e.g., lettuce and poultry) and current diseases international travelers may encounter, remains the responsibility of the CDC (2020i). Inanimate objects can also harbor organisms, such as the influenza virus, which may be spread if a person touches a contaminated article and then touches their nose or eyes. Nurses need to pay special attention to transferring organisms. For example, a nurse with artificial nails may harbor a large number and variety of microbes under the nails. Ineffective handwashing or improper glove use may also result in exposing an immunocompromised patient to the risk of infection.

Portal of Exit

The portal of exit is the point of escape for the organism from the reservoir. The organism cannot exert its influence unless it moves away from its original reservoir. Each type of microorganism has a typical primary exit route. In humans, common portals of exit include the respiratory, gastrointestinal (GI), and genitourinary (GU) tracts as well as breaks in the skin. Blood and tissue can also be portals of exit for pathogens.

Means of Transmission

An organism may be transmitted from its reservoir by various means or routes. Some organisms can be transmitted by more than one route. Organisms can enter the body by way of contact transmission, either directly or indirectly. **Direct contact** requires close proximity between the susceptible host and an infected person or a carrier, and includes activities such as touching, kissing, and sexual intercourse. Health care workers have the potential to directly transmit organisms to susceptible people through touching. **Indirect contact** involves personal contact with either: (1) a **vector**, a living creature that transmits an infectious agent to a human, usually an insect; or (2) an inanimate object, called a **fomite**, such as equipment or countertops (Brunette & Nemhauser, 2019). Keep in mind that nurses use stethoscopes many times of the course of day—stethoscopes, especially when unclean, have the potential to act as fomites of infection. In addition to providing education and addressing misconceptions and negative attitudes, best-practice recommendations, infection control policies and procedures, and functional systems need to be in place to support stethoscope hygiene practices (Breen & Hessels, 2017). Proper hand hygiene and glove use can interrupt the transmission of dangerous bacteria from nurses to patients. Ongoing work is being done to evaluate the effectiveness of antimicrobial surfaces, such as copper, in preventing and reducing health care–associated infections (HAIs; Muller et al., 2016; Zingg et al., 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Esther Bailey**, the woman described at the beginning of the chapter in the Reflective Practice box on page 664, who was catheterized. In this situation, the catheter becomes contaminated. Indirect contact occurs if this contaminated catheter is inserted, predisposing her to an infection.

Microorganisms can also be spread through the airborne route when an infected host coughs, sneezes, or talks, or when the organism becomes attached to dust particles. Another means of transmission is through droplets. **Droplet transmission** is similar to **airborne transmission**. However, airborne particles are smaller than 5 µm (micrometer), and droplet particles are greater than 5 µm. This distinction matters when designing prevention strategies. For example, once there were data to support droplet transmission of the virus that causes COVID-19 (WHO, 2020d), frequent handwashing, disinfection of high-touch areas, social distancing (6 ft), and cloth masks for the general public became the cornerstones of transmission prevention (CDC, 2020g). These prevention recommendations continued even after vaccines became available because of the virus variants. Recommendations from WHO (2020) and other national and international guidelines specified that health care environments need to consider airborne transmission precautions with COVID-19, in addition to contact and droplet precautions (PPE required), with aerosol-generating procedures. Table 25-1 summarizes the means of transmission for several organisms, their reservoirs, and examples of diseases they transmit.

Portal of Entry

The portal of entry is the point at which organisms enter a new host. The organism must find a portal of entry to a host or it may die. The entry route into the new host is often the same as the exit route from the prior reservoir. The skin and urinary, respiratory, and GI tracts are common portals of entry.

Concept Mastery Alert

The skin and respiratory, gastrointestinal, and genitourinary tracts are common portals for organism entry and exit.

Table 25-1 Organisms Capable of Causing Disease

ORGANISM	RESERVOIR	MEANS OF TRANSMISSION	DISEASE TRANSMITTED
Borrelia burgdorferi	Ticks (sheep, cattle, deer, mice)	Contact (indirect, vectors)	Lyme disease
Escherichia coli (E. coli)	Feces Contaminated food or water	Contact (direct/indirect)	*E. coli* infection (Most common manifestation is diarrhea)
Hepatitis B virus (HBV)	Blood Feces Body fluids and excretions	Contact (direct; indirect possible, but unlikely)	Hepatitis B
Human immunodeficiency virus (HIV)	Blood Semen Vaginal secretions Breast milk	Contact (direct)	Acquired immunodeficiency syndrome (AIDS)
Mycobacterium tuberculosis (*M. tuberculosis* [TB])	Sputum (respiratory tract)	Contact (airborne)	Tuberculosis
Salmonella	Intestinal tracts of humans and other animals, including birds	Contact (direct/indirect)	Diarrheal illness

Staphylococcus aureus	Skin surface Mouth Nose Throat	Contact (direct/indirect)	• Minor skin infections: Carbuncle, boil, pimple, abscess • Respiratory infection • Endocarditis (infection of the heart valves) • Osteomyelitis (bone infection) • Bacteremia (bloodstream infections)

Susceptible Host

Microorganisms survive only in a source that provides shelter and nourishment (a host), and only if the microorganisms overcome any resistance mounted by the host's defenses. Susceptibility is the degree of resistance the potential host has to the pathogen. People who are hospitalized are often in a weakened state of health because of illness, and have less resistance. Thus, they are more susceptible to infection. Many factors influence a host's susceptibility; these are discussed later in the chapter.

Remember **Giselle Turheis**, the woman with leukemia and a compromised immune status. Her susceptibility to infection is increased because of the lack of an adequate functioning immune system.

Stages of Infection

An understanding of the stages in the development of an infection is necessary to intervene and disrupt the infection cycle. An infection progresses through the following phases:

- Incubation period
- Prodromal stage
- Full (acute) stage of illness
- Convalescent period

The course and severity of the infection, as well as the patient's response, influence the type and extent of nursing care provided.

Incubation Period

The incubation period is the interval between the pathogen's invasion of the body and the appearance of symptoms of infection. During this stage, the organisms are growing and multiplying. The length of incubation may vary. For example, the common cold has an incubation period of 1 to 2 days, whereas tetanus has an incubation period ranging from 2 to 21 days.

Prodromal Stage

A person is most infectious during the prodromal stage. Early signs and symptoms of disease are present, but these are often vague and nonspecific, ranging from fatigue and malaise to a low-grade fever. This period lasts from several hours to several days. During this phase, the patient often is unaware of being contagious. As a result, precautions are not taken, and the infection spreads to other hosts.

Full Stage of Illness

The presence of infection-specific signs and symptoms indicates the full stage of illness. The type of infection determines the length of the illness and the severity of the manifestations. Symptoms that are limited or occur in only one body area are referred to as *localized* symptoms, whereas symptoms manifested throughout the entire body are referred to as *systemic* symptoms.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Convalescent Period

The convalescent period involves the recovery from the infection. Convalescence may vary according to the severity of the infection and the patient's general condition. The signs and symptoms disappear, and the person returns to a healthy state. Depending on the type of infection, there may be a temporary or permanent change in the patient's previous health state even after the convalescent period.

A person may continually pass through the four phases with the same infectious process, such as with HSV-1. Although there may have been only one infectious exposure, the infection may continue to cycle through the phases.

Infection Defense Mechanisms

Several defense mechanisms protect the body from invasion. The skin and mucous membranes are considered first-line defenses. One of the other first-line defenders is the body's normal flora, particularly the flora found in the GI tract. Flora help to keep potentially harmful bacteria from invading the body. If a pathogen makes it past these first-line defenses, the inflammatory response and immune response help the body combat infection.

Inflammatory Response

The inflammatory response is a protective mechanism. Inflammation helps the body neutralize, control, or eliminate the offending agent, and prepare the site for repair (Hinkle et al., 2022). In addition to infection, the inflammatory response also occurs in response to injury. It is either an acute or chronic process.

The hallmark signs of acute infection are redness, heat, swelling, pain, and loss of function, usually appearing at the site of the injury/invasion. The body's response occurs in two phases that are responsible for these hallmark signs: the vascular and cellular phases. In the vascular phase, small blood vessels constrict in the area, followed by vasodilatation of arterioles and venules that supply the area. This increase in blood flow results in redness and heat in the area. Histamine is released, leading to an increased permeability of vessels, which allows protein-rich fluid to pour into the area. At this point, swelling, pain, and loss of function can occur (Norris, 2019).

During the cellular stage, white blood cells (leukocytes) move quickly into the area. Neutrophils, the primary phagocytes, engulf the organism and consume cell debris and foreign material. Exudate, composed of fluid, cells, and inflammatory byproducts is released from the wound. The exudate may be clear (serous), contain red blood cells (sanguineous), or contain pus (purulent). The amount of exudate depends on the size and location of the wound. The damaged cells then are repaired by either regeneration (replacement with identical cells) or the formation of scar tissue (Norris, 2019). Refer to Chapters 33 and 43 for additional discussion of the inflammatory response.

Immune Response

Another protective mechanism is the immune response. The normal immune response involves the collective reaction of the immune system to an invading organism. The complex mechanisms that constitute the immune response occur as the body attempts to protect and defend itself. The foreign material is called an **antigen**, and the body commonly responds to the antigen by producing an **antibody**. This antigen–antibody reaction, also known as humoral immunity, is one component of the overall immune response. The other component that also helps the body defend against invaders is cell-mediated immunity. This type of immunity involves an increase in the number of lymphocytes (white blood cells) that destroy or react with cells the body recognizes as harmful (Norris, 2019). Although these complicated chemical and mechanical responses are not completely understood, it is known that they help to defend the body specifically against bacterial, viral, and fungal infections as well as malignant (cancerous) cells.

Factors Affecting the Risk for Infection

The susceptibility of the host depends on various factors:

- Integrity of skin and mucous membranes, which protect the body against microbial invasion
- pH levels of the GI and GU tracts, as well as the skin, which help to ward off microbial invasion
- Integrity and number of the body's white blood cells, which provide resistance to certain pathogens
- Age, sex, and heredity, which influence susceptibility—neonates and older adults appear to be more vulnerable to infection (see the accompanying box: Focus on the Older Adult)
- Immunity, natural or acquired, which acts to resist infection
- Level of fatigue, nutritional and general health status, the presence of preexisting illnesses, previous or current treatments, and certain medications, which play a part in the susceptibility of a potential host
- Stress level, which if increased may adversely affect the body's normal defense mechanisms
- Use of invasive or indwelling medical devices, which provides exposure to and entry for more potential sources of disease-producing organisms, particularly in a patient whose defenses are already weakened by disease

Health habits that promote wellness can reduce potential risk factors, thus decreasing the susceptibility of a host. Sensible nutrition, adequate rest and exercise, stress-reduction techniques, and good personal hygiene habits can help maintain optimum bodily function and immune response. Condomless anal or vaginal sex, sex between an HIV-uninfected person and a person living with HIV with an unsuppressed viral load (Marcus & Snowden, 2020), and sharing intravenous (IV) needles are potentially dangerous, providing an opportunity for pathogens to enter a host and

cause an infection.

Focus on the Older Adult

AGE-RELATED CHANGES PREDISPOSING TO INFECTION

Infection Risk	Age-Related Changes	Nursing Strategies
Pulmonary infections	• Decreased cough reflex • Decreased elastic recoil of lungs • Decreased activity of cilia • Abnormal swallowing reflexes	• Place patient in sitting position to eat and drink. • Encourage patient to drink plenty of fluids, unless contraindicated. • Encourage patient to cough and deep breathe or use incentive spirometer. • Recommend pneumococcal vaccination (per guidelines) and influenza vaccination annually.
Urinary tract infections (UTI)	• Incomplete emptying of bladder • Decreased sphincter control • Bladder-outlet obstruction due to enlarged prostate gland • Pelvic floor relaxation due to estrogen depletion • Reduced renal blood flow	• Discuss with patient need to void at regular intervals. • Encourage patient to drink plenty of fluids, unless contraindicated. • Administer medications for enlarged prostate (benign prostate hypertrophy; BPH) and estrogen depletion as prescribed. • If patient wears absorbent product such as incontinence pad, instruct patient to change pad frequently and perform good perineal care. • Assess for UTIs (may be atypical clinical presentation in older adults). • Discuss the need for patient to void after sexual intercourse.
Skin infections	• Loss of elasticity • Increased dryness • Thinning of epidermis • Slowing of cell replacement • Decreased vascular supply	• Encourage patient to drink plenty of fluids, unless contraindicated. • Help patient to perform good hygiene practices daily. • Apply lotion to skin as needed. • Assess frequently for any breaks in skin integrity, rashes, or changes in skin.

Note: Atypical clinical manifestations of infection in an older adult include confusion, disorientation, lethargy, anorexia, delayed fever response, falls, incontinence, and failure to thrive.

Box 25-1 **Laboratory Data Indicating an Infection**

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Elevated white blood cell (leukocyte) count—normal value is 5,000 to 10,000/mm^3
- Increase in specific types of white blood cells—referred to as a differential or differential count (percentage of each cell type)

• Neutrophils	Normal = 60%–70%	Increased in acute infections that produce pus; increased risk for acute bacterial infection if decreased; may also be increased in response to stress
• Lymphocytes	Normal = 20%–40%	Increased in chronic bacterial and viral infections
• Monocytes	Normal = 2%–8%	Increased in severe infections: function as a scavenger or phagocyte
• Eosinophils	Normal = 1%–4%	May be increased in allergic reaction and parasitic infection
• Basophils	Normal = 0.5%–1%	Usually unaffected by infections

- Elevated erythrocyte sedimentation rate—red blood cells settle more rapidly to the bottom of a tube of whole blood when inflammation is present
- Presence of pathogen(s) in cultures of urine, blood, sputum, or other (wound) drainage

Think back to **Esther Bailey**, the woman being catheterized who also has developed a postoperative wound infection. Undergoing abdominal surgery disrupts the integrity of the skin and mucous membranes, thereby increasing her risk for a wound infection.

NURSING PROCESS FOR INFECTION PREVENTION AND CONTROL

It is imperative that health care providers safeguard the people entrusted to their care by controlling diseases and preventing the spread of infection. Vigilant preventive care can limit exposure to potentially harmful infectious organisms and reduce the occurrence of infection. Public health nurses and other professionals often initiate follow-up including contact tracing, which involves identifying people with an infectious disease and locating individuals and groups with whom they have come into direct contact to interrupt actual or potential transmission of the infectious disease (CDC, 2020j).

Assessing

The nurse plays a critical role in preventing and controlling infection. This role begins with early detection and surveillance techniques. The extent of nursing interventions depends on the susceptibility of the host, the virulence of the organism, and the patient's signs and symptoms.

Inquire about the patient's immunization status and previous or recurring infections. Observe nonverbal cues and gather information about the history of the current disease. Nursing assessments include observing for signs and symptoms of a local or systemic infection. A localized infection can result in redness, swelling, warmth in the involved area, pain or tenderness, and loss of function of the affected part. Manifestations of a systemic infection include fever, often accompanied by an increase in pulse and respiratory rate, lethargy, tenderness and enlargement of lymph nodes, and anorexia. Laboratory data can provide further insight into the presence of an infectious process. Any of the laboratory test results outlined in Box 25-1 may indicate the presence of an infection.

Compilation of these assessment data leads to the development of a unique nursing database that outlines potential nursing interventions for patients at risk for infection or those in whom an infection is already present.

Diagnosing

The potential for infection or the presence of an infection in a patient may lead to diagnosing actual or potential health problems or needs. These identified problems and needs guide the development and communication of a coordinated plan that often involves the interprofessional team. Examples of health problems and needs with related etiology and signs and symptoms can be found in the box titled Examples of Actual or Potential Health Problems or Needs: Asepsis and Infection Control on page 672.

Outcome Identification and Planning

The nurse develops appropriate patient outcomes after reviewing the assessment data, considering the cycle of events

resulting in an infection, and incorporating the principles of infection control. Planning outcomes that prevent infection or disrupt the infection cycle presents an exciting challenge. Nursing interventions focused on controlling or preventing infection can positively impact patient outcomes. The following examples of expected patient outcomes are appropriate for preventing infection and using infection control techniques. The patient will:

- Demonstrate effective hand hygiene and good personal hygiene practices
- Identify the signs of an infection
- Maintain adequate nutritional and fluid intake
- Demonstrate proper disposal of soiled articles
- Use appropriate cleansing and disinfecting techniques
- Verbalize awareness of the necessity of proper immunizations
- Implement stress-reduction techniques
- Adhere to infection control precautions (isolation, equipment, visitors)
- Verbalize an understanding of health risks associated with a latex allergy

Examples of Actual or Potential Health Problems or Needs

ASEPSIS AND INFECTION CONTROL

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Dehydration	• Insufficient fluid intake • Insufficient knowledge about fluid needs • Fluid loss secondary to underlying infection	• Decrease in blood pressure, pulse pressure, and pulse volume • Dry mucous membranes • Increase in body temperature • Sudden weight loss • Weakness and other neurologic symptoms
Infection risk	• Alteration in skin integrity • Inadequate vaccination • Insufficient knowledge to avoid exposure to pathogens	—
Knowledge deficiency	• New and evolving standards of care and infection control practices	• Inability to articulate current infection control standards • Unwillingness to adhere to guidance regarding infection control

Source: Wolters Kluwer. (2020). Problem-based care plans. In Lippincott advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

Implementing

The practice of **asepsis** includes all activities to prevent infection or break the chain of infection. The nurse uses aseptic techniques to halt the spread of microorganisms and minimize the threat of infection. There are two asepsis categories: medical asepsis and surgical asepsis. **Medical asepsis**, or clean technique, involves procedures and practices that reduce the number and transfer of pathogens. Medical asepsis procedures include performing hand hygiene and wearing gloves. **Surgical asepsis**, or sterile technique, includes practices used to render and keep objects and areas free from microorganisms. Surgical asepsis procedures include inserting an indwelling urinary catheter or inserting an IV catheter.

Using Medical Asepsis

Medical asepsis techniques are used continuously both within and outside health facilities, based on the assumption that pathogens are likely to be present. For example, shared drinking cups are considered unsanitary because a person harboring pathogens may transfer those pathogens to the cup. In a health care facility, if a specific pathogen is known to be present, special methods of medical asepsis are used to prevent further spread of the organism. Nearly every nursing activity includes practices of medical asepsis. Therefore, the nurse assumes responsibility for breaking the cycle of infection by providing safe patient care that protects the patient and the nurse from microorganisms that may

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

cause disease. Box 25-2 highlights the basic practices of medical asepsis for nurses to routinely use when providing care to patients.

Limiting the dissemination of pathogens will decrease the transfer of pathogens from person to person. The most practical way to accomplish this is through the use of barriers that prevent transmission of the pathogens. Barriers are ways to decrease the spread of pathogens and include hand hygiene, personal protective equipment (PPE, discussed later), and other barrier techniques. Figure 25-2 shows how barriers break the infection cycle. Nurses must understand the various precautions or barrier techniques if they are to use them correctly and minimize infection risks to patients as well as to themselves (see Promoting Health 25-1 on page 674).

PERFORMING HAND HYGIENE

Hand hygiene is the most effective way to help prevent the spread of infectious agents. There is consensus that most health care–associated pathogens are transmitted via the contaminated hands of health care workers. According to an ongoing survey supported by the CDC, there were an estimated 1 in 31 hospitalized patients with an HAI, which has decreased since the original survey in 2011 (Magill et al., 2018). The CDC's initial guidelines for hand hygiene in health care settings remain largely unchanged (Healthcare Infection Control Practices Advisory Committee, 2017). The term *hand hygiene* applies to either handwashing with plain soap and water, the use of antiseptic handrubs including waterless alcohol-based products, or surgical hand antisepsis. Although there is agreement that hand hygiene is the most important procedure for preventing infections, hand hygiene is still not performed consistently in health care settings. A recent review of the literature found that the average baseline compliance rate for handwashing (based on the results from 16 studies performed primarily in the United States and Europe 2009–2014) was only 34.1%. The average compliance rate for handwashing increased to 56.98% after the implementation of various multimodal, multifaceted educational, and motivational interventions (Kingston et al., 2016). Other initiatives to support the evidence-based practice of handwashing highlight the benefits of positive role models (including leaders and managers), establishing a socially and culturally supportive clinical environment, the provision of ongoing education and training, and readily available supplies (Hammerschmidt & Manser, 2019; Kingston et al., 2017). Review the Research in Nursing box (on page 674) for another perspective on improving hand hygiene.

Box 25-2 Practicing Basic Principles of Medical Asepsis in Patient Care

- Practice good hand hygiene.
- Carry soiled linens or other used articles/equipment so that they do not touch your clothing.
- Do not place soiled bed linen or any other items on the floor, which is grossly contaminated. It increases contamination of both surfaces.
- Avoid allowing patients to cough, sneeze, or breathe directly on others. Provide them with disposable tissues, and instruct them to cover their mouth and nose to prevent spread by airborne droplets.
- Move equipment away from you when brushing, dusting, or scrubbing articles. This helps prevent contaminated particles from settling on the hair, face, and clothing.
- Avoid raising dust. Use a specially treated cloth or a dampened cloth. Do not shake linens. Dust and lint particles constitute a vehicle by which organisms may be transported from one area to another.
- Clean the least soiled areas first and then the more soiled ones. This helps prevent having the cleaner areas soiled by the dirtier areas.
- Dispose of soiled or used items directly into appropriate containers. Wrap items that are moist from body discharge or drainage in waterproof containers, such as plastic bags, before discarding into the refuse holder so that handlers will not come in contact with them.
- Pour liquids that are to be discarded, such as bath water or mouth rinse, directly into the drain to avoid splattering in the sink and onto you.
- Sterilize equipment suspected of containing pathogens.
- Use practices of personal grooming that help prevent spreading microorganisms. Examples include shampooing the hair regularly, keeping hair short or pinned up to limit the possibility of carrying microorganisms on hair shafts, keeping fingernails short and free of broken cuticles and ragged nail edges, and avoiding wearing rings with grooves and stones that may harbor microorganisms.
- Follow guidelines conscientiously for standard and transmission-based precautions as prescribed by your facility.

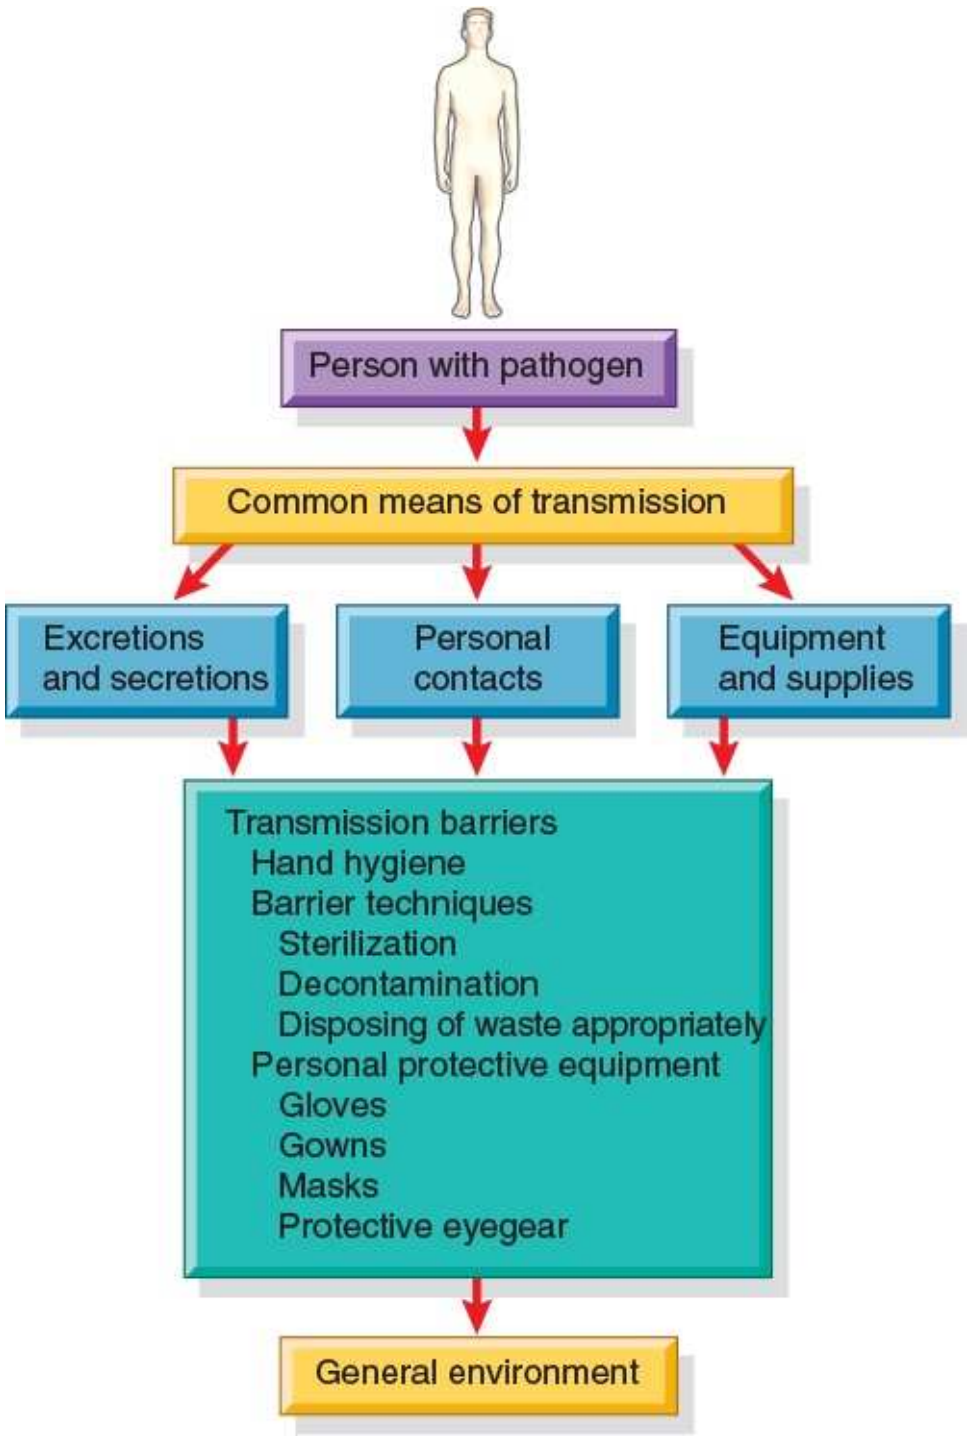

FIGURE 25-2. Transmission barriers help prevent the transporting of pathogens from the infected person to the general environment.

The WHO (2020c) defined *My 5 Moments for Hand Hygiene*. These include:

- Moment 1—Before touching a patient
- Moment 2—Before a clean or aseptic procedure
- Moment 3—After a body fluid exposure or risk of exposure
- Moment 4—After touching a patient
- Moment 5—After touching patient surroundings

The Joint Commission Center for Transforming Healthcare continues its campaign inviting all Joint Commission–accredited organizations to improve patient safety and lower the cost of health care. The Hand Hygiene Project takes advantage of their Targeted Solutions Tool (TST) that facilitates a "step-by-step process to accurately measure their organization's actual performance, identify their barriers to excellent performance, and direct them to proven solutions that are customized to address their particular barriers" (The Joint Commission Center for Transforming Healthcare, 2020, p. 1). The targeted solutions tool and associated increase in hand hygiene has resulted in a 45% reduction in HAIs (up from 26% reduction) and saved up to 2.8 million dollars in direct medical costs (The Joint Commission Center for Transforming Healthcare, 2020).

Promoting Health 25-1

INFECTION CONTROL PRECAUTIONS AND BARRIER TECHNIQUES

Use the assessment checklist to determine how well you are observing infection control or barrier precautions as you care for patients in a health care facility or in a community setting. Then develop a prescription for self-care by choosing appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

☐	☐	☐	1. I perform hand hygiene before and after contact with a patient.
☐	☐	☐	2. I choose the evidence-based option for hand hygiene depending on the situation (e.g., alcohol-based, pain soap and water, antimicrobial/antiseptic soap and water).
☐	☐	☐	3. I wear PPE if contact with blood or body fluids is a possibility.
☐	☐	☐	4. I cover my nose and mouth when coughing and sneezing and properly dispose of tissues.
☐	☐	☐	5. I use additional protective equipment (gowns, masks, goggles, face shields) as appropriate.
☐	☐	☐	6. I avoid recapping any used or contaminated needles.
☐	☐	☐	7. I place needles or other sharp objects in a puncture-proof disposable container.
☐	☐	☐	8. I dispose of used or contaminated objects and equipment in a leak-resistant plastic trash bag.
☐	☐	☐	9. I am a role model for hand hygiene.
☐	☐	☐	10. I collaborate with leadership to hold people accountable, identify access points for hand hygiene, and establish places to store items to accommodate hand hygiene.

Self-Care Behaviors

1. Read infection control standards published by OSHA and CDC.
2. Attend programs that provide updates on current CDC/OSHA policies and survey literature regularly to determine best practices.
3. Maintain strict personal hygiene habits.
4. Obtain immunizations when available.
5. Assess for any signs and symptoms of an infection.
6. Perform hand hygiene frequently.
7. Perform hand hygiene immediately after removing gloves.
8. Practice cough etiquette to prevent transmission of respiratory infections.
9. Protect myself with the barriers necessary to prevent exposure to blood, body fluids, or secretions.
10. Follow facility policy if any exposure to blood or body substance occurs.
11. Never eat, drink, smoke, apply cosmetics or lip moistener, or handle contact lenses in an area where occupational exposure is possible.
12. Make hand hygiene a habit.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Hand Hygiene Compliance in the ICU: A Systematic Review

Despite the fact that hand hygiene is recognized as a key element in preventing the spread of infection, there are still significant issues with compliance in health care, even in ICUs where patients are already compromised. Hand hygiene noncompliance persists despite global efforts to impact change.

Related Research

Lambe, K. A., Lydon, S., Madden, C., Vellinga, A., Hehir, A., Walsh, M., & O'Connor, P. (2019). Hand hygiene compliance in the ICU: A systematic review. *Critical Care Medicine*, *47*(9), 1251–1257. https://doi.org/10.1097/CCM.0000000000003868

A systematic review considered 61 peer-reviewed studies focused on hand hygiene compliance, primarily in high-income countries (60.7%) and in adult intensive care units (ICUs; 85.2%). Overall, mean hand hygiene compliance internationally is 59.6%, which falls below the accepted standard that ranges from 80% to 90%. Of note is that compliance was higher in neonatal ICUs (67.0%) than in pediatric (41.2%) or adult ICUs (58.2%). Compliance varies by type of health care worker, with nurses at 43.4% compliance, physicians at 32.6% compliance, and other staff (e.g., respiratory therapists, custodial staff, and technicians) at 53.8% compliance with hand hygiene. Interestingly enough, compliance rates were similar whether data were collected covertly (participants did not know they were being observed) or overtly (participants were aware they were being observed).

Relevance to Nursing Practice

This systematic review highlights the need to continue targeted educational, environmental, and compliance initiatives focused on hand hygiene. Although the WHO standards have been in circulation internationally since 2009, health care compliance varies by geographic location, unit type, and composition of providers.

Table 25-2 Bacterial Flora on the Hands

TYPES OF BACTERIAL FLORA	CHARACTERISTICS	EFFECTIVE HAND HYGIENE MEASURES
Transient	• Occur on hands with activities of daily living • Relatively few in number on clean and exposed areas of the skin • Attached loosely on skin usually in grease, fats, and dirt • Found in greatest number under the fingernails • Can be pathogenic or nonpathogenic	Can be removed relatively easily by frequent and thorough handwashing
Resident	• Normally found in skin creases • Usually stable in number and type • Cling tenaciously to skin by adhesion and absorption	Considerable friction with a brush is required to remove them Less susceptible to antiseptics than transient bacteria

The CDC Foundation forged an ongoing relationship with GOJO, the inventors of PURELL Instant Hand Sanitizer, to enhance hand hygiene educational outreach to patients, health care providers, and caregivers in various health care settings in the United States. The tools and educational materials are designed to improve hand hygiene practices and ultimately reduce the number of HAIs in the United States (CDC Foundation, 2016; GOJO Industries, 2020).

Bacteria

Two types of bacterial flora are normally found on the hands: transient bacteria and resident bacteria (Table 25-2). Transient bacteria, although usually easily removed by thorough handwashing, have the potential to adjust to the environment of the skin when they are present in large numbers over a long period of time, and become resident bacteria. If pathogenic organisms become resident bacteria on the skin, the hands then become carriers of that particular organism. Therefore, to help prevent transient bacteria from becoming resident bacteria, it is important to clean the hands promptly when they are visibly soiled, after each contact with contaminated materials, and after removing gloves. In addition, the seminal CDC guideline for hand hygiene in health care settings (2002) specifies that health care personnel involved in patient care should not wear artificial nails because they are more likely to be associated with higher bacterial counts. In fact, wearing artificial nails in the operating room (OR) is a citable offense during The Joint Commission accreditation process. Natural nails should be less than 1/4 inches long.

Cleansing Agents

Various hand hygiene products are available. Soaps and detergents, also referred to as nonantimicrobial agents, are considered adequate for routine mechanical cleansing of the hands and removal of most transient microorganisms. They work by lowering surface tension and acting as emulsifying agents. Bar, liquid, leaflet, and powdered soaps are all effective. Use of a particular product in a health care facility often depends on personnel or facility preference.

Using handwashing products that contain an antimicrobial or antibacterial ingredient is recommended in any setting where the risk for infection is high. When present in certain concentrations, these agents can kill bacteria or suppress their growth. Numerous studies that informed the landmark 2006 Institute for Healthcare Improvement (IHI, 2020b) guidance documented that alcohol-based handrubs, in most situations, more effectively reduce bacterial and viral counts on the hands of health care personnel than antimicrobial soap (IHI, 2020b). Alcohol-based handrubs have an alcohol concentration between 60% and 95% and are available as foam, gel, or lotions.

Techniques

If the health care worker's hands are not visibly soiled, alcohol-based handrubs are recommended because they save time, are more accessible and easy to use, and reduce bacterial count on the hands. The following are clinical situations when an alcohol-based handrub can be used to decontaminate hands (IHI, 2020b.)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Before direct contact with patients
- After direct contact with patient's skin
- After contact with body fluids, mucous membranes, nonintact skin, and wound dressings, if hands are not visibly soiled
- After removing gloves
- Before inserting urinary catheters, peripheral vascular catheters, or invasive devices that do not require surgical placement
- Before donning sterile gloves prior to an invasive procedure (e.g., inserting a central venous access device)
- When moving from a contaminated body site to a clean body site during patient care
- After contact with objects (including equipment) located in the patient's environment

When used repeatedly, alcohol-based handrubs cause less dryness and skin irritation than soap products. Those who have sensitive or dry skin may benefit from use of an alcohol-based product that contains humectants, such as glycerine, or other emollients or moisturizers (Berardi et al., 2020; Gold & Avva, 2020). See Guidelines for Nursing Care 25-1 for directions on how to use an alcohol-based handrub.

Guidelines for Nursing Care 25-1

Hand Hygiene: Using an Alcohol-Based Handrub

- Apply product to the palm of one hand, using the amount of product recommended on the package (it will vary according to the manufacturer but usually is 3 mL and may require dispensing two pumps).
- Rub hands together, making sure to cover all surfaces of the hands, fingers, and in between the fingers. Also, clean the fingertips and the area beneath the fingernails.
- Continue rubbing until the hands are completely dry (at least 20 seconds).

Concept Mastery Alert

Alcohol-based handrubs are a quick way to remove germs when hands are not visibly soiled.

Alcohol-based hand sanitizers are effective against gram-positive and gram-negative bacteria including multidrug-resistant pathogens such as methicillin-resistant *Staphylococcus aureus* (MRSA) or vancomycin-resistant enterococci (VRE), HIV, influenza, HBV, and hepatitis C virus (HCV). They are also highly effective in halting the spread of seasonal flu, rhinovirus (the most common cause of colds), and many emerging viral pathogens such as Ebola virus disease (EVD), Zika virus, and severe acute respiratory syndrome coronavirus (SARS-CoV-2). The use of alcohol-based handrubs are less effective with *Cryptosporidium* (a waterborne parasite), norovirus (related to contaminated food), and *C. diff*, so soap and water are recommended. For example, *C. diff* is a gram-positive, anaerobic, spore-forming bacterium that is a common cause of diarrhea. It affects children, adults, and older adults. The morbidity and mortality associated with *C. diff* infections (CDIs) has motivated health care providers to improve prevention strategies. Alcohol does not kill *C. diff* bacterial spores; it only kills the vegetative form of the cell. One theory posits that when exposed to water, the endospore swells and the protective walls of the endospore burst (Yoo, 2018), but other theories posit the soap and rubbing associated with handwashing cause spore death. Either way, in the absence of definitive research, soap and water are the preferred hand hygiene method when these infections are suspected or diagnosed (Berardi et al., 2020; Gold & Avva, 2020). Glove use remains the cornerstone for preventing transmission, and contact precautions including a private/cohorted room and gown use are recommended until diarrhea stops. CDI is discussed later in this chapter.

If a health care worker's hands are visibly soiled or contaminated with blood or body fluids, washing the hands with antimicrobial soap and water is required. Handwashing is also required before eating and after using the restroom. Effective handwashing requires at least a 20-second scrub with plain soap or disinfectant and warm water. Hands that are visibly soiled need a longer scrub. Recommended handwashing techniques for medical asepsis are listed in Skill 25-1 on pages 692–694.

Hand antisepsis before assisting with a surgical procedure involves a lengthier scrub to reduce resident and transient flora on the forearms and hands. This procedure, known as a surgical hand scrub, incorporates surgical asepsis and is described in texts that deal with operating and delivery room procedures. Since 2002, CDC guidelines recommend using an antimicrobial soap or alcohol-based surgical hand scrub product for surgical hand antisepsis. Scrub time is also reduced significantly when alcohol-based scrub agents are used.

Preventing Health Care–Associated Infections

For various reasons and sometimes despite best efforts, certain patients in health care facilities develop **health care–associated infections (HAIs)**. The term HAI encompasses and has replaced the term nosocomial, which was used

specifically to indicate something originating or taking place in a hospital. Infections that are community acquired and not associated with health care are differentiated from HAIs. An HAI develops as a result of medical care and may occur in many health care settings including hospitals, rehabilitation facilities, outpatient settings, and dialysis centers. The source of an HAI may be either exogenous or endogenous. An infection is referred to as **exogenous** when the causative organism is acquired from other people. An **endogenous** infection occurs when the causative organism comes from microbial life harbored in the person. An infection is referred to as **iatrogenic** when it results from a treatment or diagnostic procedure.

Prevention of HAIs is a major challenge for health care providers. Although this number has been on the decline since 2014, HAIs account for tens of thousands of deaths and billions of dollars in additional health care costs annually (Agency for Healthcare Research and Quality [AHRQ], 2019). The cost of the additional hospital care days necessary to treat an HAI is staggering, particularly in light of the efforts to control spiraling health care expenses. With its focus on patient safety, The Joint Commission mandated that death or serious injury caused by an infection-related event must be reported as a sentinel event (see Chapter 28 for a discussion of sentinel events; The Joint Commission, 2020). As of 2013, the Centers for Medicare and Medicaid Services (CMS) no longer reimburses hospitals for specific preventable *hospital-acquired conditions* (HACs). These HACs are high cost and/or high-volume occurrences that could be reasonably prevented with adherence to evidence-based guidelines; when they occur, HACs result in higher costs. Specific HAIs (catheter-associated UTIs, vascular catheter–associated infections, and various surgical site infections [SSIs]) are included in CMS's current 14 categories of HACs (CMS, 2020). As part of the Hospital-Acquired Condition Reduction Program (HACRP), CMS payments for 2019–2020 were reduced 1% for hospitals ranked in the 25% of worst-performing hospitals with respect to risk-adjusted HAC quality measures. Although this is an evolving process, there is potential that the critical impact that nurses have on decreasing the number of HAIs will be recognized and more easily verified.

Healthy People 2030 (2021) identifies opportunities for addressing existing infection control policies and practices in outpatient settings. These settings include ambulatory surgical centers, dialysis centers, traditional outpatient offices and clinics, and long-term care facilities. Expanding prevention efforts across the continuum of care is essential to the prevention of HAIs.

Based on the premise that most HAIs are preventable, in 2008 the U.S. Department of Health and Human Services (USDHHS; 2021), in conjunction with multiple other federal facilities, formed a Federal Steering Committee committed to coordinating strategies to reduce the transmission of HAIs. The most recent HAI action plan for 2015–2020 recently completed, with seven targets tracked. These include:

- Catheter-associated urinary tract infection (CAUTI)
- Surgical site infection (SSI)
- Central line–associated bloodstream infection (CLABSI)
- Invasive health care–associated and hospital-onset methicillin-resistant *Staphylococcus aureus* (MRSA) infections
- *Clostridioides difficile* (*C. diff*) infections (CDIs) and CDI hospitalizations

USING INVASIVE MEDICAL DEVICES

Most HAIs are caused by bacteria, such as *C. diff*, *E. coli, S. aureus, Streptococcus faecalis, Pseudomonas aeruginosa,* and *Klebsiella* species. Many HAIs can be traced to an invasive device, such as a urinary catheter or venous access catheter. For example, UTIs represent more than 9.5% of the infections reported by hospitals, and virtually all health care–associated UTIs are related to procedures and instrumentation involving the urinary tract. Approximately 12% to 16% of hospitalized adults have an indwelling urinary catheter placed; each patient has a 3% to 7% increased risk of acquiring a CAUTI each day the catheter remains in place (CDC, 2020b). Infection control measures include adherence to recommended best practices, or bundles. **Bundles** are typically three to five evidence-based practices that, when implemented together, improve patient outcomes (IHI, 2020a). The American Nurses Association (ANA, n.d.) initiative to prevent CAUTI outlines three areas of focus: (1) prevention of inappropriate short-term urinary catheter use, (2) timely removal of catheters that is nurse driven, and (3) catheter care during placement. Focused initiatives, like the one from the ANA, have resulted in changes in practice; however, surveillance, reporting, and prevention initiatives are still mandated and important. CLABSIs have a high mortality rate and are very costly. Central line insertion and maintenance guidelines, like those from the CDC and The Joint Commission (2013), clearly outline handwashing and aseptic technique when handling central lines. The 5-year target goal for CLABSI is a 50% reduction in the number of cases; recent figures show a 9% reduction between 2017 and 2018, with an 11% decrease reported in intensive care units (ICUs; CDC, 2019c).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Consider **Esther Bailey**, the 72-year-old woman who has had abdominal surgery and developed a wound infection. The patient already has one infection. However, insertion of the catheter increases her risk for an additional infection, directly related to the use of the catheter.

The USDHHS Federal Steering Committee's (2020) target of 30% reduction in surgical site infections is on track, with a 17% decrease seen in targeted SSIs between 2008 and 2014 (CDC, 2016). Patients receiving mechanical ventilation are especially at risk for ventilator-associated pneumonia (VAP). This infection occurs when pathogens gain access to a patient's lungs via either an endotracheal or tracheostomy tube. VAP bundles provide an excellent example of how simultaneous implementation of seemingly simple interventions such as elevating the head of the bed to 30 to 45 degrees, providing regular oral care, and changing the ventilator circuit (tubing) only as needed, can be effective in preventing infection (Hinkle et al., 2022; Klompas, 2014). With all invasive devices, whether a venous access device, urinary catheter, or endotracheal tube, the interprofessional team collaborates to determine and document the necessity of a device, adheres to standards of care for insertion, and implements protocols (including bundles and guidelines) that address evidence-based infection prevention interventions.

REPORTING HEALTH CARE–ASSOCIATED INFECTIONS

Mandatory public reporting of HAI rates is required in the majority of states (CDC, 2019f). These reports contain specific data on CLABSI, CAUTI, SSI, MRSA, and *C. diff*, with additional information provided on antibiotic resistance and emerging infections. Check this link to see if your state is required by law to report HAI data: https://www.cdc.gov/HAI/state-based/required-to-report-hai-NHSN.html (see Additional Resources). Advocates of mandatory reporting believe that all facilities should report HAI rates. This public disclosure allows consumers to make more informed choices regarding their selection of a health care facility based on an institution's efforts to prevent HAIs. The expectation is that electronic medical records will serve as a surveillance system for tracking these events, thus streamlining the processes and providing an infrastructure for tracking. Keep in mind that several factors influence the speed with which initiatives like this one are embraced (AHRQ, 2014):

- Environmental factors: Who does this change benefit? Is the change mandatory?
- The nature of the innovation: Is it easy to understand? Is there strong evidence to support the change?
- Whether or not people can make the change: Can one person make a difference? Can we individualize the decision making?
- Organizational factors: Are there competing priorities, resource issues, and/or multiple decision makers?

DEALING WITH MULTIDRUG-RESISTANT ORGANISMS

A significant and disturbing trend continues to be the development of microorganisms, primarily bacteria (but also parasites, viruses, and fungi), resistant to one or more classes of antibiotics (or antimicrobials) that were originally effective to treat these infections (WHO, 2020a). The indiscriminate use of broad-spectrum antibiotics has allowed once-susceptible bacteria to develop defenses against antibiotics. While antibiotics kill bacteria that cause illness, they also affect good bacteria that protect the body from infection. As a result, the drug-resistant bacteria continue to grow and can even share their drug resistance with other bacteria, which further complicates treatment (CDC, 2019g). Resistant organisms MRSA, VRE, and carbapenem-resistant Enterobacteriaceae (CRE) have emerged. The CDC (2019g) lists four core actions to fight resistant strains:

- Preventing infections, thereby preventing the spread of resistance
- Tracking
- Improving antibiotic prescribing/stewardship
- Developing new drugs and diagnostic tests

Although this chapter will review some of the more urgent threats and most commonly known resistant infections, data and the associated prevention and treatment guidelines are always evolving. A good resource is the CDC's 2019 *Antibiotic Resistance Threats in the United States* that can be found at: https://www.cdc.gov/drugresistance/pdf/threats-report/2019-ar-threats-report-508.pdf; the 2013 version is also available on the site for comparison data.

Methicillin-Resistant *Staphylococcus aureus*

S. aureus bacteria are normally found in the nasal mucous membranes, on the skin, and in the respiratory and GI tracts. Approximately one third of the people in the United States are colonized with *S. aureus*, meaning that the organism is present (typically in the nose), but the person does not have symptoms and remains healthy and uninfected. They can, however, pass the organism on to others (CDC, 2019a). In the 1960s, a strain of *S. aureus* emerged that was resistant to the broad-spectrum antibiotic methicillin, which is the drug of choice used to treat these infections. The very powerful antibiotic, vancomycin, had to be used to treat the MRSA infections that, at that time, primarily occurred in health care settings. In the late 1990s, a type of MRSA appeared in the wider community. The prevalence of community-associated MRSA (CA-MRSA), a common cause of skin and soft tissue infections in the United States, has been increasing rapidly. Those most at risk are young children, older adults, and people in close physical proximity to others, including athletes, military personnel, inmates, and daycare attendees (CDC, 2019c; Gupta et al., 2015).

Treatment options for CA-MRSA begin with the use of good handwashing, PPE, and disinfection/sterilization of equipment by health care providers who come into contact with CA-MRSA. Guidelines currently recommend incision and drainage of abscesses in patients who are afebrile and healthy with mild, uncomplicated abscesses. Antimicrobial therapy may not be required. If incision and drainage are not effective and systemic or serious infection results, antimicrobial therapy may be necessary. Prior to antibiotic therapy, wound drainage should be sent for culture and sensitivity testing. Patient follow-up education includes encouraging frequent handwashing and maintenance of good personal hygiene, reviewing wound care techniques and the necessity of completion of prescribed treatment, and developing a prevention plan based on the identification of potential sources of infection (Gupta et al., 2015).

The health care–associated MRSA strain, on the other hand, has more serious implications. Patients who have surgery, have invasive devices, are immunocompromised, or who have longer hospital stays are at risk for developing an MRSA infection (Wang et al., 2015). MRSA can be responsible for bloodstream infections, wound infections, VAP, and multidrug resistance. IV vancomycin remains one of the first-line medications for the treatment of health care–associated MRSA (Cong et al., 2019; Pryor et al., 2020). In a health care setting, the main mode of transmission is through direct contact with the contaminated hands of health care personnel or indirect contact with equipment (CDC, 2019a). National data indicate that there was a 17% decrease in hospital-onset MRSA bloodstream infection rate each year between 2005 and 2013, but no significant changes occurred between 2013 and 2016. There were an estimated 323,700 cases in 2017, with 10,600 deaths (CDC, 2019g). Basic infection control practices remain the key to the prevention and control of MRSA.

Vancomycin Intermediate-Resistant *Staphylococcus aureus*, Vancomycin-Resistant *Staphylococcus aureus*, and Vancomycin-Resistant Enterococci

In the 1990s, following the increased use of vancomycin to treat MRSA, vancomycin intermediate-resistant *Staphylococcus aureus* (VISA) emerged in the United States, followed in 2002 by VRSA that was totally resistant to vancomycin (Pryor et al., 2020). Once bacteria develop drug resistance, they progress from being sensitive to an antibiotic, to an intermediate resistance, followed by complete resistance to the antibiotic. Since October 2010, all cases of VISA and VRSA have been successfully treated with other drugs approved by the U.S. Food and Drug Administration, and cases remain extremely rare. Patients most at risk of developing VISA and VRSA are those with a history of kidney disease or diabetes, a previous MRSA infection, presence of an invasive catheter, or recent exposure to vancomycin. Effective infection control measures are imperative to control the spread of VISA and VRSA; prudent use of vancomycin is an important preventive measure (Virginia Department of Health, 2018).

VRE are another serious pathogen in hospitals. Enterococci, a species of *Streptococcus* found in normal GI and GU tracts, can cause HAIs with a high mortality rate if the organism is vancomycin resistant. As the enterococci mutate and develop acquired and intrinsic resistance to mainstay drugs such as vancomycin, ampicillin, and gentamycin, providers continue to give targeted therapy (such as the synthetic antibiotic linezolid or daptomycin) in an effort to treat the infection and reduce complications (Levitus et al., 2020; see Table 25-1 on page 668). Risk factors for VRE are similar to other HAIs and include compromised immune systems, recent surgery, invasive devices, prolonged antibiotic use (especially vancomycin), and prolonged hospitalization.

VRE is spread via contact with the feces, urine, or blood of an infected or colonized person. In 2017, there were an estimated 54,500 cases of VRE in hospitalized patients, with 5,400 estimated deaths (CDC, 2019g). Health care providers must work to ensure prompt recognition, diagnosis, isolation, management, and infection control. Nursing assessment, intervention, and evaluation of high-risk patients and situations help to minimize infection and reduce the unnecessary suffering imposed on patients. To control the transmission of both MRSA and VRE, the CDC and a large volume of published evidence continue to support contact precautions along with meticulous hand hygiene, reducing the use of invasive devices, environmental cleaning, and decolonizing high-risk patients. Some institutions have removed contact precautions from this bundle and instead include standard precautions; they have noted no significant change in the incidence of MRSA or VRE (Pryor et al., 2020).

Carbapenem-Resistant Enterobacteriaceae

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

CRE are very difficult to treat and represent a public health threat. This disease was first reported in 2001 in the United States and is associated with a 40% to 50% mortality rate. *Klebsiella* species and *E. coli* are examples of Enterobacteriaceae normally found in the human intestine. Carbapenem antimicrobial drugs are broad-spectrum antimicrobials and the agents of choice for serious infections when an organism is resistant to other primary antibiotics. Resistance to carbapenems leaves few other treatment options. These organisms are readily passed from patient to patient, but rarely impact healthy people. People who have bladder or venous catheters in place, those who require ventilator assistance to breathe, patients with open surgical wounds, those taking antibiotics for a lengthy period of time, or people who have frequent hospitalizations (especially in an ICU) or long-term care facility stays are at risk for developing CRE. The plan of care requires laboratory testing to detect resistance to carbapenems; decisions on treatment of infections with CRE are based on these results. In 2017, there were an estimated 13,100 cases of CRE in hospitalized patients, with 1,100 deaths (CDC, 2019g). The CDC (2019g) recommends that the patient be placed on contact precautions. A focus on hand hygiene and education regarding prevention of CRE transmission are vital to prevent transmission of the deadly infection.

Acinetobacter Baumannii

Carbapenem-resistant *Acinetobacter baumannii* (CRAB) is a gram-negative bacterium found primarily in hospitals; those with immune issues, chronic lung disease, or diabetes may be more susceptible. It has spread through health care facilities, infecting 8,500 people that resulted in 700 deaths in 2017 (CDC, 2019g). CRAB has developed resistance to many antibiotic regimens, severely limiting treatment options and resulting in myriad clinical trials and observational studies to investigate alternative approaches to treat CRAB (Piperaki et al., 2019). When patients transition from one level of care to another, acute care, long-term care, and rehabilitation health care workers must maintain high-quality contact precautions to minimize the transfer of CRE (including CRAB) to another facility (Pryor et al., 2020). Because *A. baumannii* can also sustain itself in the environment, the patient's room and all mechanical equipment must be cleaned and disinfected to eliminate fomite transmission.

Clostridioides Difficile

Although not an antibiotic resistant infection, *C. diff* is caused by similar factors and is directly related to antibiotic use and resistance. National data indicate almost 223,900 people in the United States required hospitalization for *C. diff*, with at least 12,800 deaths attributed to *C. diff* (CDC, 2019g). While health care–associated (hospital and long-term care facilities) cases of CDIs are decreasing, community-associated cases of CDI are not. Although adults and children are both affected, CDI is seen largely in older adults. Both symptomatic and asymptomatic people serve as reservoirs for *C. diff,* as do any surfaces or objects contaminated with feces. This organism normally resides in the intestinal tract. When antibiotics (particularly broad-spectrum antibiotics) are prescribed or taken for a prolonged period of time, helpful bacteria are destroyed, and *C. diff* bacteria can grow out of control, creating a bacterial imbalance. Watery diarrhea, fever, and mild abdominal cramping are some of the more common signs and symptoms, but the severity of CDI depends on the specific strain (CDC, 2019e; Dubberke et al., 2014). Prevention is the key. General strategies to reduce the indirect transmission of CDI include (CDC, 2019e; Dubberke et al., 2014):

- Confirming CDI in patients with appropriate diagnostic testing protocols
- Avoiding the use of electronic equipment that is difficult to clean (electronic thermometers)
- Disinfecting dedicated patient care items and equipment (stethoscopes) between patients
- Using terminal cleaning protocols (including *C. diff* sporicidal agents) for patient-care areas and equipment with patient transfers and discharge
- Using full-barrier contact precautions (gown and gloves)
- Placing patients in private rooms; cohort patients with the same strain of CDI
- Performing meticulous hand hygiene (discussed earlier in this chapter on pages 672–675)
- Performing environmental contamination of rooms
- Educating health care providers (and patients/families as appropriate) on clinical presentation, transmission, and epidemiology of CDI
- Facilitating antibiotic stewardship (prescribing only when needed; minimizing high-risk antibiotic use)

QSEN *Clostridioides Difficile (C. Diff)* Infection

Remember that CDI is not killed by alcohol-based handrubs, so soap and water are required.

In addition to recognition of CDI and prevention of transmission, keep in mind that best practice involves the measured use of antimicrobials—prescribing them at an appropriate dose and only when indicated. Antibody-based therapies may be used to manage patients with recurrent *C. diff* infections (CDC, 2019g).

STERILIZING AND DISINFECTING

Cleansing, disinfection, and sterilization help break the cycle of infection and prevent disease. Several processes are used to destroy microorganisms. **Disinfection** destroys all pathogenic organisms except spores; **sterilization** destroys all microorganisms, including spores/endospores (Yoo, 2018). Disinfection can be used when preparing the skin for a procedure or cleaning a piece of equipment that does not enter a sterile body part. Sterilization is usually performed on equipment that is entering a sterile portion of the body. Disinfection and sterilization of contaminated or infected objects and good hand hygiene diminish and often eliminate microorganisms as potential sources of infection.

Method Selection

Various factors influence the choice of sterilization and disinfection methods, including the following:

- Nature of organisms present: The CDC recommends that all supplies, linens, and equipment in a health care setting should be treated as if the patient were infectious. Some organisms are easily destroyed, whereas others can withstand certain common sterilization and disinfection methods.
- Number of organisms present: The more organisms present on an item, the longer it takes to destroy them.
- Type of equipment: Equipment with small lumens, crevices, or joints requires special care. Certain articles that may be damaged by various sterilization and disinfection methods require special handling.
- Intended use of equipment: The need for medical or surgical asepsis influences the preparation and cleaning of equipment. In the home, it may be safe to use equipment and supplies that are clean, but most health care facilities use sterilized articles for patient care.
- Available means for sterilization and disinfection: The choice of chemical or physical means of sterilization and disinfection depends on the nature and number of organisms, the type and intended use of the equipment, and the availability and practicality of the means. Table 25-3 lists the types of methods for sterilization and disinfection.
- Time: Time is a key factor when sterilizing or disinfecting articles. Failure to follow the recommended time periods is grossly negligent.

Using Personal Protective Equipment and Supplies

According to the 1992 Occupational Safety and Health Administration (OSHA) ruling, health care facilities must provide employees with the equipment and supplies necessary to minimize or prevent exposure to infectious material. This **personal protective equipment (PPE)** includes gloves, gowns, masks, and protective eye gear. Skill 25-2 on pages 695–700 illustrates the proper use of this equipment.

Gloves

Gloves are not a substitute for good hand hygiene. They are worn only once and discarded appropriately according to facility policy. Then hands are thoroughly decontaminated with meticulous hand hygiene. When nursing care activities do not involve the possibility of soiling the hands with body fluids, gloves are not necessary. Activities such as turning a patient, feeding a patient, taking vital signs, and changing IV fluid bags do not require the use of gloves as long as the potential contact with body fluids is not present. However, when there is a possibility of soiling the hands with body fluids, gloves must be worn.

Each patient interaction requires a clean pair of gloves. Some care activities for an individual patient may necessitate changing gloves more than once. Gloves should always be changed prior to moving from a contaminated task to a clean one. While wearing gloves, never leave the patient's room (unless transporting a contaminated item or moving a patient requiring transmission-based precautions), never write in the patient's chart, and never use the computer keyboard or telephone in the nurses' station. Also, health care workers should not touch their pagers, cell phones, or other facility-based communication devices without first performing good hand hygiene. Mobile phones, which are ubiquitous, fit easily into lab coat or scrub pockets where dirty hands can come into contact with the device. The dark, warm pockets are a breeding ground for thousands of microbes. Several studies confirm that touch screens and phones have microbe growth in 82% to 88% of the mobile phones tested. The good news is that hand hygiene is an effective means to stop the cycle of contamination (Cobb & Lazer, 2020).

Wearing gloves does not eliminate the need for proper hand hygiene. In reality, the warmth and moisture inside gloves create an ideal environment for bacteria to multiply, making it even more important to perform good hand hygiene before and after using gloves. Evidence-based practice supports that gloving does not guarantee complete protection from infectious organisms. Gloves provide a barrier but are not impenetrable. It has been shown that many times glove-barrier failure goes undetected by the health care worker. Double gloving (putting on two gloves on one hand) is recommended if the health care worker is involved in a procedure during which exposure to blood or body fluids is expected, such as in an operating room (OR) setting where evidence indicates that glove perforations were reduced by 71% with double gloving (Association of periOperative Registered Nurses, 2020).

Table 25-3 Methods of Sterilization and Disinfection

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

METHOD	DISCUSSION	CAUTION
Physical		
Steam	Higher temperature caused by higher pressure destroys organisms (e.g., autoclaving)	Most plastic and rubber devices are damaged by autoclaving
Boiling water	Frequently used in the home—simple and inexpensive; boil item for at least 10 minutes	Spores and some viruses are not destroyed by boiling
Dry heat	Alternative sterilization method for home Used for metal items Heat oven to 350°F for 2 or more hours	Insufficient to destroy all microorganisms; not used in health care facilities
Radiation	Used for pharmaceuticals, foods, plastics, and other heat-sensitive items	Object must be directly exposed to ultraviolet radiation on all surfaces Poses risk to personnel
Chemical		
Ethylene oxide gas	Destroys microorganisms and spores/endospores by interfering with metabolic processes in cells Gas is released while items (oxygen and suction gauges, blood pressure equipment) are contained in autoclave	Precautions necessary because gas is toxic to humans
Chemical solutions	Generally used for instrument and equipment disinfection and for housekeeping disinfection Chlorines are useful for disinfecting water and for housekeeping purposes A solution of sodium hypochlorite (household bleach) in a 1:100 dilution effectively inactivates human immunodeficiency virus. Betadine and alcohol are also used as disinfectants	Method does not destroy all spores and may cause corrosion on metal surfaces

Sensitization to latex varies among health care workers based on their role and actual exposure to latex. Approximately 10% of health care workers and 1% to 2% of the general population are sensitized to traditional latex (Burkhart et al., 2015; Occupational Safety and Health Administration [OSHA], n.d.). Reactions to latex fall into three categories: (1) irritant contact dermatitis that results from contact with gloves where the hands become irritated and dry—this is not actually not an allergy; (2) allergic contact dermatitis (a type IV sensitivity), which is an actual reaction to the latex that results in localized pruritus (itching), erythema (redness or rash), and urticarial lesions 24 to 96 hours after the contact; and (3) a true latex allergy (a type I hypersensitivity) where there is an immediate systemic response that may result in anaphylaxis (Burkhart et al., 2015; National Institute for Occupational Safety and Health [NIOSH], 2012a). The cornstarch powder or talc used to make gloves easier to put on is a causative factor in latex allergy development, which is why there has been a move to powder-free gloves in the clinical setting. The powder binds with the latex protein and becomes airborne, thus contaminating the environment (Henry et al., 2020). Powder particles may be inhaled or absorbed into skin or mucous membranes or enter the bloodstream. It is important to remember that repeated exposures to latex have been shown to lead to a latex sensitivity. If a person continues to be exposed to latex after a sensitivity has developed, that person may demonstrate signs of a latex allergy. At present, there is no cure for a latex allergy.

The NIOSH (2012a) recommends that nonlatex gloves or powder-free, low-allergen latex gloves (if latex gloves are used) be available for use. Also, according to the OSHA Personal Protective Equipment Standard 1910.132 (2016), employers must provide alternative gloves if necessary. Because a completely *latex-free* environment is considered unattainable given the ubiquitous nature of latex, a *latex-safe* health care environment is essential for patients and health care providers with a latex allergy. All health care facilities are required to have a written policy

that identifies how to deal with latex-sensitive employees and patients. Awareness of an allergy to latex is also important for safe home care. See Box 25-3 (on page 682) for information on latex allergy for health care personnel and patients.

Gowns

Gowns are usually worn to prevent soiling of the health care worker's clothing by the patient's blood and body fluids. They provide barrier protection and are donned immediately before entering the patient's room. Individual gown technique is recommended. This technique involves wearing a gown only one time and then discarding it appropriately according to facility policy. A waterproof or impervious gown is used if there is an increased likelihood of contact with a patient's blood or body fluids. If a gown becomes heavily soiled or moistened with blood or body fluids when caring for a patient, remove it, perform thorough hand hygiene, and put on a clean gown. There is no single special technique for applying a gown used as a barrier, but recommended practices for removing a soiled gown are described in Skill 25-2 on pages 695–700.

Box 25-3 **Latex Allergy Summary**

Risk Factors

- Occupational exposure to latex (includes health care professionals)
- People with allergic tendencies
- People with food allergies, specifically banana, papaya, avocado, potatoes, kiwi fruit, chestnuts, and pineapples
- People with asthma, spina bifida, or a history of multiple surgical procedures or exposures to latex

Frequently Used Products that Contain Latex

- Gloves
- Blood pressure cuffs
- Electrode pads
- Stethoscopes
- IV tubing
- Urinary catheters
- Tourniquets
- Syringes
- Surgical masks
- Baby bottle nipples and pacifiers

Types of Reactions

- *Irritant contact dermatitis:* most common reaction usually restricted to hands that have come into contact with latex; symptoms include dry, irritated skin associated with pruritus
- *Allergic contact dermatitis or delayed hypersensitivity:* allergic contact dermatitis, displayed as dry, crusty bumps, erythema, pruritus, scaling vesicles, papular lesions at site of contact, including the palms; symptoms usually appear in 24 to 96 hours
- *Latex allergy or immediate hypersensitivity:* systemic reactions usually happen within minutes of exposure; displayed as rhinitis, conjunctivitis, angioedema, bronchospasm, shock, and/or systemic anaphylactic reactions; this is a life-threatening sensitivity that is rarely the first reaction to latex exposure

Diagnosis

- RAST (radioallergosorbent test): blood test for IgE antibodies to latex
- Skin prick: small amount of serum derived from latex placed on small prick in skin

Treatment

- Prevention: avoidance of latex-containing products
- Localized reaction: treat with oral diphenhydramine, cool compresses, and hydrocortisone 1% cream
- Systemic reaction: possibly treated with epinephrine subcutaneously, systemic steroids, antihistamines, with transport to the emergency department
  - Remove all latex-containing articles from the room
  - Place three-way stopcocks in IV lines for medication administration; place tape over any injection ports on IV tubing

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Patient Teaching (If Diagnosed With Latex Allergy)

- Avoid all latex-containing products and avoid inhaling powder used in latex gloves
- Inform employer and other health professionals of latex allergy
- Wear medical alert bracelet
- Follow doctor's recommendations
- Inform health care provider/nurse of allergy prior to any injections/immunizations; a latex-free vial stopper should be used
- Ensure that health care provider is aware of allergy prior to any medical procedure or surgery

Masks

Surgical masks, which are FDA approved, and procedure/isolation masks help prevent biologic particles from being disseminated into the air by the wearer. Masks help prevent the wearer from coming into direct contact with known or suspected infected body fluids (such as blood) that may spray or splash. When worn properly, masks also protect the wearer from exposure to large particle pathogens (>5 μm in size) spread through close respiratory or mucous membrane contact with respiratory droplets. These droplets are generated by coughing, sneezing, or talking, and they typically travel less than 3 ft but may reach 6 ft in certain instances. (See Transmission-Based Precautions later in this chapter.) Particulate respirators are used to prevent the inhalation of either airborne droplet nuclei or small particle aerosols (≤5 μm in size), which can remain suspended in the air and travel longer distances (see Transmission-Based Precautions later in this chapter; Siegel et al., 2019).

Various mask practices are used. In some instances, all personnel and all the patient's visitors wear masks while in the patient's room. In other situations, the patient wears the mask when transported outside their room to either protect health care personnel and other patients from exposure to pathogens, or to protect the patient.

In the clinical setting, a mask is typically worn only once and not lowered around the neck and then brought back over the mouth and nose for reuse. How long one can wear a mask while caring for one patient is the subject of debate. Regardless of the time worn, a mask must be changed before it becomes damp from the wearer's exhalations. See Skill 25-2, pages 695–700 for the recommended practice for applying and removing a mask.

FIGURE 25-3. The N95 health care particulate respirator is NIOSH approved. It meets CDC guidelines for tuberculosis exposure control and is designed specifically for use in a health care setting. *(Source: Courtesy of 3M Health Care.)*

A particulate respirator filters inspired air; surgical masks filter only expired air. One of the most commonly used respirators is the N95 respirator, which is designed to filter airborne particles as small as 1 μm with 95% efficiency and fits comfortably against the face (Fig. 25-3). The elastic straps on these respirators provide more protection and a better fit than the ties on regular surgical masks, but fit-testing is required to ensure health care workers are using the appropriate mask size (CDC, 2020h; OSHA, 2011; Siegel et al., 2019). Once a fit test has been completed to determine the best respirator size, a seal check should be done every time the respirator is worn to ensure an adequate seal (Krah et al., 2018).

The serious increase in the number of multidrug-resistant tuberculosis cases prompted new guidelines to prevent the transmission of this disease. According to CDC guidelines, a NIOSH-certified N95 respirator or higher-level respirator must be worn when entering the airborne infection isolation (AII) room of a patient with known or suspected tuberculosis. These AII rooms are single-occupancy patient rooms designed for airborne transmission with environmental controls including negative pressure, an air flow rate of 6 to 12 air changes per hour, and direct venting of exhaust to the outside or the use of a high efficiency particulate air (HEPA) filter. Other infections or conditions

that may be airborne such as EVD, influenza, coronavirus (MERS-CoV and SARS-CoV-2), and Zika viruses require standard, contact, droplet, and/or airborne precautions (CDC, 2019d; Siegel et al., 2019). We will address some of these specific cases later in this chapter.

Think back to **Jackson Ray Ivers**, the son coming to visit his mother who is hospitalized with a new-onset fever and cough after exposure to a friend with a highly communicable respiratory virus. The nurse would incorporate knowledge of respiratory transmission and appropriate barriers to explain to Mr. Ivers why they need to wear a mask or a respirator while visiting.

Protective Eyewear

Protective eyewear, such as goggles or a face shield, must be available whenever there is a risk of contaminating the mucous membranes of the eyes. For example, suctioning a tracheostomy or assisting with an invasive procedure that may result in splattering of blood or other body fluids requires protection for the caregiver. Plain glasses are unacceptable because side shields are required.

HANDLING AND DISPOSING OF SUPPLIES

Used equipment may be disposed of after use or, if reusable, bagged according to facility policy, sent to a central cleaning area, and sterilized or disinfected. Double bagging may be required if the single bag is not secure or is soiled on the outside. A contaminated item must never be used for another patient.

Some linen bags are water soluble and dissolve in hot water, making it unnecessary for workers to handle the contaminated linen. The use of paper trays and plastic eating utensils does not prevent transmission of organisms and is no longer recommended. The combined hot water and detergent used in commercial dishwashers sufficiently decontaminates dishes, glasses, and utensils. All spills of body fluids or substances must be immediately cleaned with the appropriate chemical germicide or disinfectant.

When collecting a specimen, take care to prevent the outside of the container from becoming contaminated with any secretions or body fluids. Place all laboratory specimens in plastic bags and seal the bags to prevent leakage during transportation. A red bag marked *BIOHAZARD* is used to dispose of trash that contains liquid or semiliquid blood or other potentially infective material (OPIM), trash contaminated with blood or OPIM that would release these substances if compressed, and trash that is caked with dried blood or OPIM and is capable of releasing these materials during handling.

USING STANDARD AND TRANSMISSION-BASED PRECAUTIONS

In addition to barriers, specific precautions have been established to prevent the transmission of infection. Historically, health care workers employ **isolation**, a protective procedure that limits the spread of infectious diseases among hospitalized patients, hospital personnel, and visitors. Infection control programs, interprofessional teams, and other health care workers require a shared understanding of core principles to guide the development of and adherence to policies and procedures designed to create an environment dedicated to infection control and prevention.

Current Centers for Disease Control and Prevention Guidelines

The 2007 CDC guideline (Siegel et al., 2019) recognizes that health care delivery occurs in other settings beside acute care hospitals. This guideline, focused on preventing transmission of infectious agents in myriad health care settings, replaces the 1996 guideline and is updated periodically online as new information becomes available. This publication marks the transition from the narrow term *nosocomial infection* (hospital-acquired) to the broader term, *health care–associated infection* (associated with health care delivery in any setting). These guidelines reflect the emergence of new pathogens, methods to prevent transmission of multidrug-resistant organisms, and the CDC's concern regarding biologic terrorism. Nurses must understand the various precautions or barrier techniques if they are to use them correctly and minimize infection risks to patients as well as to themselves (see Promoting Health 25-1 on page 674).

The long-standing CDC guidelines (Siegel et al., 2019) continue to designate two tiers of precautions:

- **Standard precautions:** precautions used in the care of all hospitalized patients regardless of their diagnosis or possible infection status. These precautions apply to blood, all body fluids, secretions, excretions (except sweat),

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

nonintact skin, and mucous membranes. New elements included in standard precautions are respiratory hygiene/cough etiquette, safe injection practices, and directions to use a mask when performing high-risk prolonged procedures involving spinal canal punctures. Elements of respiratory hygiene and cough etiquette include education of staff and patients, posted instructions for the population served, review of source control measures (e.g., using masks on patients who are coughing and appropriate use of tissues with sneezes), reinforcement of hand hygiene (especially with managing secretions), and spatial separation when possible.

- **Transmission-based precautions:** precautions used in addition to standard precautions for patients in hospitals with suspected infection with pathogens that can be transmitted by airborne, droplet, or contact routes. The 2007 CDC guidelines include a directive to don PPE when entering the room of a patient with transmission-based precautions, and to remove the PPE only when leaving the room. These categories recognize that a disease may have multiple routes of transmission.

The three types of transmission-based precautions (airborne, droplet, or contact) may be used alone or in combination, but always in addition to standard precautions. Box 25-4 summarizes the current CDC guidelines along with a listing of specific recommendations for both tiers of precautions. Hospitals are encouraged to tailor these recommendations as needed for implementation of their infection control strategy.

Although supported by the CDC and other infection control facilities, the efficacy of using contact precautions to prevent the spread of multidrug-resistant organisms, such as MRSA, continues to be considered. For example, there is little support in the literature for the routine use of contact precautions in MRSA, especially when it is endemic and colonization rates are high. Recommendations continue to support ongoing education of standard precautions and good handwashing (Pryor et al., 2020). As diseases, infections, or conditions emerge or their prevalence increases, guidelines need to evolve. For example, when EVD emerged as an impending issue in 2014, the CDC issued revised guidelines for health care workers caring for these patients. The revised guidelines focus on repeated hands-on training with PPE before treating patients, avoidance of skin or respiratory exposure when PPE is worn, and supervision by a trained monitor during the complex application and removal of PPE.

Recall **Jackson Ray Ivers**, the son of a patient with a new-onset fever and cough after exposure to a friend with a highly communicable respiratory virus. Based on the nurse's knowledge of disease transmission, the nurse institutes droplet (with occasional airborne) precautions for the patient and instructs Mr. Ivers regarding the need for proper hand hygiene and the use of a mask or respirator.

In late 2019, SARS-CoV-2 and the disease it causes (COVID-19) created a pandemic unlike anything we have seen in the modern world. Since COVID-19 so greatly affected people worldwide, chances are good the section on masks was particularly interesting. Let's take a moment to talk about the underlying infection control principles that guided the experts during COVID-19. Since it is a novel virus, data and the associated specific recommendations were changing rapidly, but the underlying principles were fairly consistently applied. For example, when this first started and the mechanism for transmission was largely unknown, acute care facilities moved to requiring standard, contact, and airborne precautions (respirators and AII rooms) for patients with suspected or diagnosed COVID-19. Finite resources complicated the situation in health care, and there was a move to reuse, reallocate, and reconsider possible alternatives in the move to crisis planning. As experts surveyed the pandemic and had some evidence that COVID-19 was predominantly spread via contact and/or droplet routes, the move was made to consider droplet precautions (masks and face shields) in general health care interactions, as dictated by resources. Respirators were reserved for aerosol-generating procedures (e.g., during endotracheal intubation, a bronchoscopy, or suctioning), where the virus was thought to become airborne and be transmitted via fine/small particle aerosols over greater than 3 ft within a defined airspace. In these instances, the nose and mouth are protected by a particulate respirator, the eyes protected by goggles or a face shield, and the rest of the body protected with gloves and a gown (Siegel et al., 2019). The combination of the rapid spread, previous experience with SARS, an overwhelmed health care system, and core infection control principles, led experts to make some clear infection control recommendations for the general public that included: (1) handwashing, the foundation of all infection control practices, to decrease potential fomite and mucous membrane transfer (especially with untrained mask donning and doffing); (2) handmade cloth masks to prevent the spread of droplets, while protecting the supply of health care grade products for health care workers; (3)

social distancing of 6 ft to reflect the estimated distance seen with SARS transmission; and (4) restrictions on large group, especially indoor, activities where transmission was more likely to occur via droplet or airborne mechanisms.

Box 25-4 **Summary of 2007 CDC Guidelines for Isolation Precautions in Health Care Settings**

Standard Precautions (Tier 1)

- *Follow hand hygiene techniques*.
- *Wear clean nonsterile gloves* when touching blood, body fluids, excretions or secretions, contaminated items, mucous membranes, and nonintact skin. Change gloves between tasks on the same patient as necessary and remove gloves promptly after use.
- *Wear personal protective equipment* such as mask, eye protection, face shield, or fluid-repellent gown during procedures and care activities that are likely to generate splashes or sprays of blood or body fluids. Use gown to protect skin and prevent soiling of clothing.
- *Follow respiratory hygiene/cough etiquette.* Any patients, family members, and visitors with undiagnosed, transmissible respiratory infections require education to cover their mouth and nose with a tissue when coughing and promptly dispose of the tissue. During periods of increased occurrence of respiratory infections, offer a surgical mask to coughing patients and other symptomatic people upon entry to the health care facility or office. Encourage the coughing patient to maintain more than a 3-ft separation from other people in the health care facility or office.
- *Avoid recapping used needles.* Choose needles with safety devices that can be activated with one hand. If you must recap, never use two hands. Use a needle-recapping device or the one-handed scoop technique. Place needles, sharps, and scalpels in appropriate puncture-resistant containers after use.
- *Use safe injection practices* including single-dose vials when possible; use disposable needles and syringes for each injection, and prevent contamination of injection equipment and medication.
- *Wear face mask* if placing a catheter or injecting material into the spinal or epidural space.
- *Handle used patient care equipment that is soiled with blood or identified body fluids, secretions, and excretions carefully* to prevent transfer of microorganisms. Clean and reprocess items appropriately if used for another patient.
- *Use adequate environmental controls* to ensure that routine care, cleaning, and disinfection procedures are followed.
- *Review room assignments carefully.* Place patients who may contaminate the environment in private rooms (such as a patient who is incontinent).

Transmission-Based Precautions (Tier 2)

The following precautions are recommended in addition to standard precautions:

Airborne Precautions

Use these for patients who have infections that spread through the air such as tuberculosis, varicella (chicken pox), and rubeola (measles).

- Place patient in a private room that has monitored negative air pressure in relation to surrounding areas, 6 to 12 air changes per hour, and appropriate discharge of air outside, or monitored filtration if air is recirculated. Keep door closed and patient in room.
- Wear a respirator when entering room of patient with known or suspected tuberculosis. If patient has known or suspected rubeola (measles) or varicella (chicken pox), respiratory protection should be worn unless the person entering room is immune to these diseases.
- Transport patient out of room only when necessary and place a surgical mask on the patient if possible.
- Consult CDC guidelines for additional prevention strategies for tuberculosis.

Droplet Precautions

Use these for patients with an infection that is spread by large-particle droplets such as rubella, mumps, diphtheria, and the adenovirus infection in infants and young children.

- Use a private room, if available. Door may remain open.
- Wear PPE upon entry into the room for all interactions that may involve contact with the patient and potentially contaminated areas in the patient's environment.
- Transport patient out of room only when necessary and place a surgical mask on the patient if possible.
- Keep visitors 3 ft from the infected person.

Contact Precautions

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Use these for patients who are infected or colonized by a multidrug-resistant organism (MDRO).

- Place the patient in a private room, if available.
- Wear PPE whenever you enter the room for all interactions that may involve contact with the patient and potentially contaminated areas in the patient's environment. Change gloves after having contact with infective material. Remove PPE before leaving the patient environment, and wash hands with an antimicrobial or waterless antiseptic agent.
- Limit movement of the patient out of the room.
- Avoid sharing patient-care equipment.

(2019, July). *2007 Guideline for isolation precautions: Preventing transmission of infectious agents in healthcare settings (Last update: July 2019)*. https://www.cdc.gov/infectioncontrol/pdf/guidelines/isolation-guidelines-H.pdf

PREVENTING OCCUPATIONAL EXPOSURES

OSHA developed the Bloodborne Pathogens Standard in 1991 to protect health care workers from exposure or risk of exposure to pathogens such as HIV and HBV. This was revised in 2000 by the passage of The Needlestick Safety and Prevention Act that had more specifications for employers and more detail about how health care providers should participate in decisions and ensure safe practice regarding needlestick injuries and bloodborne exposures (Occupational Safety and Health Administration, 2012). The Needlestick Safety and Prevention Act requires health care providers to:

- Identify and provide safer medical devices that reduce or eliminate injuries from sharps
- Involve health care workers in the selection process of these safer devices
- Provide engineering controls for sharps disposal containers, self-sheathing needles, and other safety devices to reduce or eliminate sharps injuries
- Educate employees regarding how to safely use these devices
- Develop a sharps injury surveillance log

Although sharps injuries declined following the implementation of the revised standards in 2001, that decline has not continued (International Safety Center, 2020). Results from a national survey indicate that, based on data received from 170 hospitals in 2016 and 224 hospitals in 2017, the rate of injuries from sharps has risen every year for the last 3 years and now matches rates reported in 2001 to 2005. Close to 40% of these injuries occurred in surgery, and teaching hospitals had higher rates than nonteaching hospitals (Grimmond & Good, 2019). In an effort to highlight this ongoing issue, many nursing and health care organizations, including the ANA, developed a Consensus Statement and Call to Action that originally focused on: (1) improving sharps safety in the surgical setting, (2) understanding and reducing exposure risks in nonhospital settings, (3) involving front-line health care workers when choosing safety devices, (4) addressing gaps in safety devices and consider innovations, and (5) enhancing education and training. These consensus statements that began in 2010 continue to provide broad recommendations that target health care facilities, professional associations, organizations that set standards, manufacturers, regulatory agencies, and accrediting organizations. The group focuses on a system-level approach that is data-driven and proactive (International Safety Center, 2020).

Needlestick injuries are also a significant occupational hazard for health care workers visiting private homes (see Box 25-5). Keep in mind that although nurses may suffer the largest proportion of needlestick injuries (Grimmond & Good, 2019), it is not always the nurse or original person using the device who sustains the injury. Other clinicians, housekeeping, or laundry staff could also come in contact with these devices and sustain an injury.

The most serious risk associated with needlestick injuries or mucous membrane exposure is the possible risk of infection with pathogens such as HBV, HCV, and HIV. Health care facilities now purchase needles with built-in safety features and needleless, protected, or recessed IV systems. Although this equipment is more expensive, the higher costs may be budget neutral due to fewer needlestick injuries. Knowledge of safety devices and prevention of bloodborne pathogen exposures create a safer workplace environment and protect nurses from potentially life-threatening injuries.

REPORTING ACCIDENTAL EXPOSURES

Although system-level controls must work to minimize exposures and establish a safe work environment (International Safety Center, 2020; NIOSH, 2015), nurses also bear responsibility for their own safety. Any needlestick injury or accidental exposure to blood or body fluids must be reported immediately so that appropriate action can be taken. Underreporting of exposures is believed to be widespread. Reasons for not reporting exposures include belief that the injury is insignificant or that the actual risk is relatively small, reporting it requires too much time, concern about negative consequences if the injury is reported, and belief that these types of injuries are to be expected. It is imperative that nurses and other health care workers report these injuries promptly so that they receive

any appropriate postexposure treatment and prophylaxis. A facility's plan for this type of exposure typically includes the following recommendations supported by the CDC and NIOSH (National Clinician Consultation Center, 2020):

Box 25-5 Preventing Needlestick Injuries to Home Health Care Workers

Nurses working in private homes need to be aware of the factors that contribute to risks in these settings. They include:

- Avoid using needles whenever safe and effective alternatives are available.
- Use needles with safety devices; void recapping or bending needles that might be contaminated.
- Bring standard-labeled, leak-proof, puncture-resistant sharps containers to the patients' homes and promptly dispose of used needles and sharps in this container.
- Plan for safe handling and disposal of needles before use.
- Keep sharps container out of the reach of children, pets, and anyone not needing access to it.
- Ensure that sharps container is secure to prevent spilling before transporting it.
- Follow standard precautions, infection prevention, and general hygiene practices consistently.
- Participate in your employer's bloodborne pathogens training program.
- Help your employer elect and evaluate safety devices and equipment.
- Use devices with safety features provided by your employer.
- Report any needlestick or other sharps injury immediately to your employer.

Source: Adapted from National Institute for Occupational Safety and Health (NIOSH). (2012b). *NIOSH Fast Facts–Home healthcare workers: How to prevent needlestick and sharps injuries*. DHHS (NIOSH) Publication No. 2012–123. http://www.cdc.gov/niosh/docs/2012-123/pdfs/2012-123.pdf

- Immediate management of the exposure site—wash the exposed area immediately with warm water and soap, flush mucous membranes, or irrigate eyes
- Immediate, detailed report of the incident to the facility, with likely completion of an incident or injury report
- Baseline testing of the source person first, with permission, to determine HCV, HBV, and HIV status (rapid HIV testing preferred); baseline testing of the exposed person indicated with positive results from the source person; note if the exposed person is considered immune to HBV with documented positive titer and requires no further testing or follow-up
- Postexposure prophylaxis (PEP), if recommended; consideration of pregnancy and lactation
- Follow-up testing as recommended—can be at 6 weeks, 3 months, and/or 12 months, depending on the exposure
- Counseling sessions regarding safe practices to protect self and others

PROVIDING CARE IN SPECIAL SITUATIONS

Occasionally, nurses need to use neutropenic precautions for a patient whose immune system is compromised (e.g., recovering from transplantation surgery or receiving chemotherapy). Those who are immunosuppressed more often than not become infected by organisms harbored in their own bodies, rather than by pathogens present in the environment or transmitted from other people. As with all hospitalized patients, standard precautions are required, but some additional measures are helpful when a patient's ability to withstand any bacterial invasion is compromised.

Recommendations in this situation include the following:

- Ensure that health care provider is healthy
- Restrict visits from friends and family members who have colds or contagious illnesses
- Avoid collection of standing water in the room (e.g., humidifiers) to prevent bacteria typically found in this water
- Avoid plants and flowers—soil is a source of bacteria and mold
- Follow hospital protocols regarding PPE for neutropenic precautions

The latest CDC (Siegel et al., 2019) guideline also addresses environmental controls that foster a *protective environment* to decrease the risk of infection in the most severely immunocompromised patients.

The increasing number of people who are ill or immunocompromised, coupled with increasingly virulent organisms, poses sterilization and disinfection concerns for home environments. Common measures that reduce the risk of infection at home include the following (OncoLink, 2020):

- Wash hands frequently—for the affected person and everyone who comes in contact with the affected person—especially before preparing food, before eating, and after using the restroom
- Maintain a clean home and frequently use household disinfectants and antibacterial wipes
- Avoid sharing personal items
- Perform regular, thorough oral care using a soft-bristled toothbrush

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Minimize the risk of injury—avoid sunburn, cuts, suppositories, tampons, and intercourse/penetration with sexual paraphernalia/oral sex
- Do not handle animal waste
- Avoid crowds, public pools, and adults or children who are sick or recently vaccinated
- Clean and disinfect kitchen surfaces, especially when preparing meat, chicken, and fish
- Cook food to the proper internal temperature; promptly refrigerate or freeze perishables, prepared foods, and leftovers
- Avoid raw meat and fish; wash all fresh fruits and vegetables; avoid soft cheese; use only pasteurized products; pay attention to sell-by dates

Controlling disease and preventing infections from spreading is a vital home care consideration for everyone.

Using Surgical Asepsis

Surgical asepsis techniques, used regularly in the operating room, labor and delivery areas, and certain diagnostic testing areas, are also used by the nurse at the patient's bedside. Procedures that involve the insertion of a urinary catheter, sterile dressing changes, or preparing an injectable medication are examples of surgical asepsis techniques. An object is considered sterile when all microorganisms, including pathogens and spores/endospores, have been destroyed. For example, the needle for an injection must be handled so that it is sterile when inserted into a patient. Sterile forceps or gloves are used to handle sterile dressings to protect against contamination. The basic principles of surgical asepsis are listed in Box 25-6 (on page 688).

When observing *medical asepsis* (clean technique), areas are considered contaminated if they bear or are suspected of bearing pathogens; whereas when following *surgical asepsis* (sterile technique), areas are considered contaminated if they are touched by any object that is not also sterile. One of the most important aspects of surgical and medical asepsis is that the effectiveness of both depends on faithful and conscientious practice by those performing them. It is far better to err on the side of safety when using surgical asepsis than to take the slightest chance of possible contamination. Being a patient advocate requires vigilant aseptic technique and a willingness to speak up if the patient's safety has been compromised by improper procedures.

Think back to **Esther Bailey**, the woman described in the Reflective Practice box (on page 664). The nurse acted appropriately by speaking up about the possible contamination of the catheter. Had this catheter been used, the patient's safety would have been compromised.

Explaining the surgical asepsis procedure to patients facilitates their cooperation. Inform the patient about which objects and areas may not be touched and direct the patient to avoid sudden movements that might contaminate the equipment. This helps the patient assist in maintaining the sterility of the procedure.

OPENING A STERILE PACKAGE AND PREPARING A STERILE FIELD

Commercially prepared sterile items may be sealed in paper or packaged in plastic containers. Sterile packages may be opened on a flat surface or while held in the hands. Skill 25-3 on pages 701–705 illustrates how to open a sterile package and prepare a sterile field. A sterile item should be covered if it is not used immediately. Reapply the cover by touching only the outside of the wrapper and reversing the opening order.

Box 25-6 Practicing Basic Principles of Surgical Asepsis

- Allow only a sterile object to touch another sterile object. Unsterile touching sterile means contamination has occurred.
- Open sterile packages so that the first edge of the wrapper is directed away from the worker to avoid the possibility of a sterile surface touching unsterile clothing. The outside of the sterile package is considered contaminated. Opening a sterile package is shown and described in Skill 25-3 on pages 701–705.

- Avoid spilling any solution on a cloth or paper used as a field for a sterile setup. The moisture penetrates through the sterile cloth or paper and carries organisms by capillary action to contaminate the field. A wet field is considered contaminated if the surface immediately below it is not sterile.
- Hold sterile objects above the level of the waist. This will ensure keeping the object within sight and preventing accidental contamination.
- Avoid talking, coughing, sneezing, or reaching over a sterile field or object. This helps to prevent contamination by droplets from the nose and the mouth or by particles dropping from the worker's arm.
- Never walk away from or turn your back on a sterile field. This prevents possible contamination while the field is out of the worker's view.
- Keep all items sterile that are brought into contact with broken skin or used to penetrate the skin to inject substances into the body or to enter normally sterile body cavities. These items include dressings used to cover surgical incisions, needles for injection, and tubes (catheters) used to drain urine from the bladder.
- Use dry, sterile forceps when necessary. Forceps soaked in disinfectant are not considered sterile.
- Consider the edge (outer 1 inch) of a sterile field to be contaminated.
- Consider an object contaminated if you have any doubt as to its sterility.

POURING STERILE SOLUTIONS

Care is necessary when pouring sterile liquids onto a sterile dressing or into a sterile basin. The outer surfaces of the bottle and cap are considered unsterile, whereas the inside areas and the solution are considered sterile. After a solution has been opened, the outer bottle should be labeled with date and time if it is to be reused. Most solutions are considered sterile for 24 hours after they are opened. When pouring from a bottle, grasp the bottle so that the label is in the palm of your hand. This action prevents any of the liquid from running over the label and making it illegible. Avoid splashing the liquid since this would contaminate the sterile field (see Skill 25-3, pages 701–705).

ADDING STERILE SUPPLIES TO A STERILE FIELD

After establishing a sterile field, it may be necessary to add items such as instruments or additional supplies to the sterile field. Item 6 in Skill 25-3 on pages 701–705 demonstrates this technique. Once a sterile field is established, objects on a field may be handled only by using sterile forceps or with hands wearing sterile gloves.

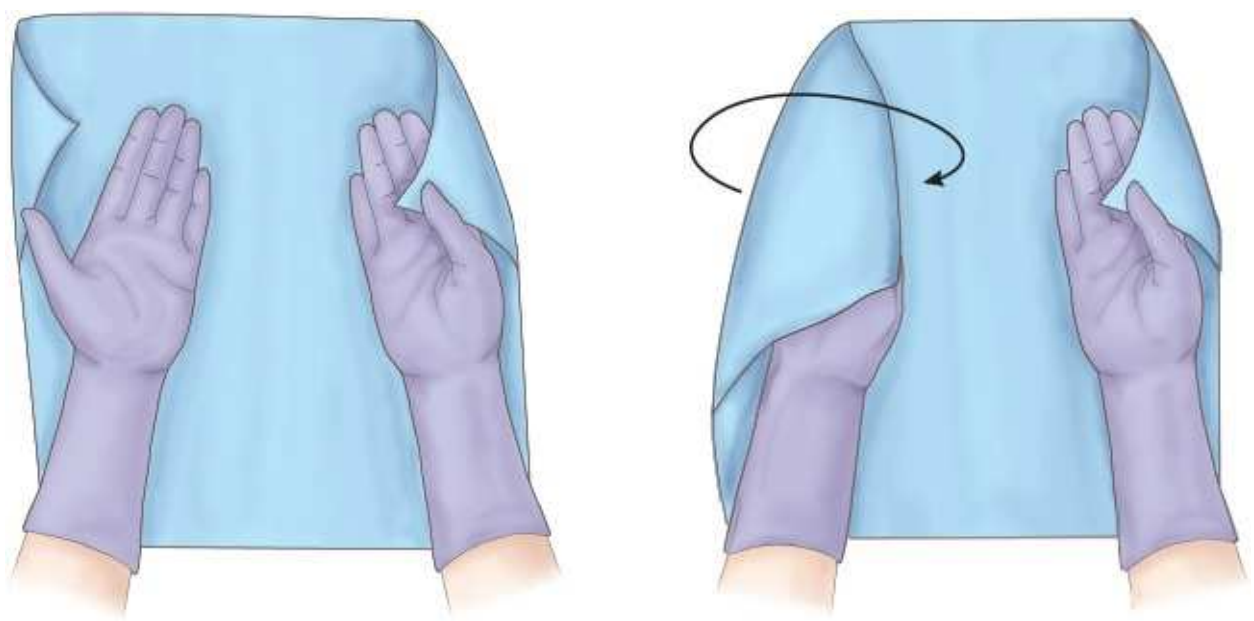

FIGURE 25-4. Techniques for cuffing a sterile drape over gloved hands.

PUTTING ON STERILE GLOVES

Sterile gloves are donned in a way that allows only the inside of the gloves to come in contact with the hands. Skill 25-4 on pages 706–709 describes the proper technique for putting on sterile gloves.

After the gloves are on, only sterile items may be handled with the sterile-gloved hands. Careful removal of the gloves reduces any hand contact with contaminated materials. Good hand hygiene technique before and after putting on sterile gloves is imperative.

POSITIONING A STERILE DRAPE

The sterile drape, which ideally is waterproof, may be used to extend the sterile working area. Using sterile gloves allows the nurse to handle the entire drape surface. For protection when positioning, fold the upper edges of the drape over the sterile-gloved hands (Fig. 25-4). When sterile gloves are not worn, the nurse can touch only the outer 1 inch (2.5 cm) of the drape. Use caution when gently shaking the drape open so as not to touch one's clothing or an unsterile object. Hold the drape by the 1-inch upper edge and position the drape over the desired area. Do not reach over the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

drape because this would contaminate the sterile area.

Through the Eyes of a Student

She was the cutest little girl I have ever known. She was infected with HIV from birth. Her mother used illicit IV drugs and engaged in condomless vaginal sex with multiple partners. This little girl, who came into the world with an innocent, fresh, new face full of unconditional love, could not walk, could not talk, could not chew, and could not control her urine or bowel movements—but she could smile unlike any other child! In the beginning, I was so terrified of contracting HIV that I couldn't walk into her room without a mask, gown, gloves, protective eyewear, and basically a full protective body spacesuit. At the end of my time with her, I wanted to take her into my home and give her all the love, support, and care she needed. I am not saying that I didn't wear gloves when I changed her diapers or when I flushed her saline lock because I did … I was very careful. But I realized that she is a person, a person full of feelings, a person who needed me, and from whom I could learn. People with the HIV virus are just that—people. We need to learn to treat them as such.

I also learned not to fear the person who is diagnosed with HIV infection or AIDS. I know that I will remember to take the proper safety precautions with this person. But I also need to have a healthy respect for the virus and check any unconscious bias when I happen to think a particular patient is or isn't the "type of person" to have HIV. If I don't consistently use standard precautions, it is possible that one day I'll become infected through contact with someone who is "not the type." If that should ever happen, I hope everyone who cares for me will treat me as a real person and not be afraid.

—Karmi N. Soder, Georgetown University, Washington, DC

Meeting Needs of Patients Requiring Infection Control Precautions

The psychological implications of infection control precautions are usually great, whether the patient is strictly separated from others or needs only to observe relatively simple precautions (see the accompanying box, Through the Eyes of a Student).

The current CDC standard precautions treat all people in a similar manner and greatly minimize the psychological trauma of feeling unclean and undesirable, which often occurred with earlier measures. However, sensory deprivation and loss of self-esteem may occur with transmission-based precautions. For example, during the pandemic that began in 2019, when shelter in place orders were in effect, when high-risk populations were encouraged to remain home, when nursing homes were in lockdown, and when family was relegated to online socialization, older adults around the world experienced profound social isolation. Unfortunately, social isolation can lead to poor physical and mental health. Specific strategies to mitigate this loneliness and build social connections included public health positive messaging, mobilizing family and community-based resources, developing accessible technology-based interventions to engage older adults, and encouraging the health care team to consider social isolation and loneliness in their health care systems (Wu, 2020). For hospitalized patients in isolation at any time, friends and relatives may be forbidden to visit. Visitors as well as health care personnel may be inclined to spend less time with the patient because they are afraid that they will contract the disease or because of the inconvenience (and discomfort) of donning, wearing, then doffing the required PPE (e.g., gowns, masks, respirators, shoe covers, and face shields). This may lead to inconsistent recording of vital signs, irregular documentation, and less patient monitoring on the part of caregivers. Research has also verified that patients placed in isolation because of the presence of a communicable disease may suffer unintended consequences such as an increase in incidents of depression and/or anxiety, fewer and shorter visits from health care providers, and a decrease in satisfaction (Kullar et al., 2016). Nursing measures to help prevent the sensory deprivation and loss of self-esteem associated with isolation precautions are discussed in Chapters 42 and 45.

Health teaching about transmission-based precautions can ease the fears of patients and family members. Both must understand the pertinent epidemiologic facts and how to carry out the specific precautions. It is helpful to emphasize the following:

- Precautions are temporary
- A clear description of the precautions and protective equipment worn by the staff to protect the patient, the caregiver, and other patients
- Proper hand hygiene before and after visiting the patient is the most effective measure to prevent spread of the disease
- Continued explanations about procedures and continued updates on progress help to empower the patient

Nurses must document their health teaching about barrier precautions in the patient's care plan. A well-informed nurse who understands how to protect both self and patients, and a well-informed patient who is cooperating in one's own care, create the best infection-prevention team.

Raising Ethical Concerns About Infection Risks

Infection control and precautions minimize infection risks for patients as well as health care workers. However, the increasing numbers of people infected with HIV, HBV, and HCV have led to serious ethical concerns and controversy related to the risk for transmitting these diseases. The rights of the patient may conflict with the rights of the health care worker and the health care facility. Refer to the accompanying box, Nursing Advocacy in Action (on page 690), for an example of a situation in which the nurse must reconcile the patient's right to make choices versus the well-being of family members.

Nursing Advocacy in Action

PATIENT SCENARIO

Mrs. Samol is a 38-year-old patient in the medical ICU who is dying of AIDS-related complications. Since being diagnosed with AIDS, she has refused to inform her husband and family of her AIDS status. She even has an advance directive, which forbids the disclosure of her diagnosis when she can no longer advocate for herself. Her husband and mother cannot understand why the doctors and nurses cannot treat her "pneumonia"—the only diagnosis she gave them. The doctors and nurses caring for Mrs. Samol believe that her husband has the right to know his wife's diagnosis so that he can make decisions in his own best interest about being tested, having their children tested, etc.

IMPLICATIONS FOR NURSING ADVOCACY

What would you do if you were Mrs. Samol's nurse? Talk with your classmates and experienced nurses about the questions that follow.

- If you elect to advocate for the Samols, what practical steps can you take to ensure better health outcomes? Are there any legal guidelines for what you can and cannot do?
- What is reasonable to expect of a student nurse, a graduate nurse, and an experienced nurse in this situation?
- What advocacy skills are needed to effectively respond to this challenge?

Questions such as the following are being debated:

- Should all hospitalized patients be routinely tested for HCV infection?
- Should HBV testing be mandatory for all foreign-born residents of the United States?
- Should health care workers infected with HIV be permitted to perform exposure-prone invasive procedures?
- Should you address hand hygiene with another RN who you have observed never washes their hands after removing gloves?
- Should pregnant health care providers be expected to care for patients with infectious diseases?
- Since standard precautions are sufficient to protect health care workers from HIV, is there a need to include this information in SBAR report? Were it not for the family dynamics should this even be mentioned?

The CDC and various medical and nursing groups are seeking consensus on these issues, based on scientific information and valid statistical evidence. Although the CDC has issued guidelines related to these topics, not all states have adopted the guidelines. In addition, some states have revised them. All agree, however, that health care workers who conscientiously adhere to appropriate infection control precautions significantly reduce the risk for infection for patients and themselves.

Working With the Infection Preventionist

In the hospital, the nurse is responsible for the collection of statistics about infection and for educating patients and staff about effective infection control techniques. Many hospitals rely on this specialized practitioner, referred to as the infection preventionist, who has demonstrated expertise in specific competencies including (Billings et al., 2019):

- Epidemiology and surveillance
- Leading investigations and surveillance programs (using surveillance technology as appropriate)
- Preventing and controlling the transmission of infectious agents
- Managing and communicating plans and feedback, as well as performance improvement and patient safety initiatives
- Leading institutions through risk assessment and implementation stages
- Leading education, research, and performance improvement activities
- Overseeing employee/occupational health

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Intensive investigative strategies create a positive environment that significantly reduces the incidence of HAIs in health care facilities. The infection preventionist knows the devastating effects of infection and is intent on promoting a safe environment while fostering a systematic approach to infection control.

In the home, the infection preventionist's duties include surveillance for facility-associated infections, education, consultation, epidemiologic investigation, quality-improvement activities, and policy and procedure development. OSHA regulations state that home care facilities must have an infection control program and that OSHA infection control standards and policies must be available to all staff for reference.

Teaching About Infection Control

Teaching about medical asepsis and infection control is a challenging nursing responsibility. Patients need to be aware of techniques that prevent the spread of infection and their rationale. COVID-19 provides a good exemplar of how misconceptions about mask requirements/recommendations belied the altruistic nature and adherence to the social contract exhibited by donning a mask in public—cloths masks did not necessarily protect the masked, they protected the community and individuals with whom the masked person came into contact. Use of the nursing process in infection control protects both the patient and the nurse.

Medical aseptic techniques are appropriate for most procedures in the home, except for self-injection technique and venous or dialysis catheter care, which require surgical asepsis. The patient frequently must make adjustments and improvise with the resources and supplies available for their use. In addition, the nurse emphasizes effective hand hygiene and other hygiene practices that interrupt the infection cycle. To satisfy OSHA requirements, many home care facilities have either a full-time or part-time infection preventionist. The Association for Professionals in Infection Control and Epidemiology (APIC, n.d.), an interprofessional organization dedicated to improving patient safety and health by reducing the risk of infection, has specific implementation guides that may be useful for educational initiatives: http://www.apic.org/Professional-Practice/Implementation-guides (see Additional Resources).

Teach patients to use basic principles of asepsis at home and in public facilities. These involve the activities of daily living (see Chapter 32 for a discussion of personal hygiene). Here are examples of medical asepsis practices recommended in the home:

- Wash hands before preparing food and before eating
- Prepare foods at temperatures high enough to ensure that they are safe to eat (e.g., preparation of fresh meat)
- Wash hands, cutting boards, and utensils with hot, soapy water before and after handling raw poultry and meat
- Keep foods refrigerated, especially those containing mayonnaise
- Wash raw fruits and vegetables before serving them
- Use pasteurized milk and fruit juices
- Wash hands after using the bathroom
- Use individual personal care items, such as washcloths, towels, and toothbrushes, rather than sharing

Note that neutropenic precautions and practices associated with medical asepsis are similar in many respects. The principles of medical asepsis are general and form a solid foundation for the more specific neutropenic precautions.

Think back to **Giselle Turheis**, the woman with leukemia and a compromised immune system. When teaching the patient about measures to prevent infection, the nurse would stress the use of proper practices in the home to reduce the patient's risk for infection.

Teach patients about ways to prevent infection in public facilities, such as the following:

- Wash hands after using any public bathroom
- Use paper towels or hot-air dryers in restrooms
- Use individually wrapped drinking straws
- Use tongs to lift food from common service trays in cafeterias, food stores, and salad bars

The community reinforces medical asepsis practices in various ways, including the following:

- Using sterilized combs and brushes in barber and beauty shops

- Performing examination of food handlers for evidence of disease
- Encouraging food handlers to receive the hepatitis A vaccination
- Enforcing frequent handwashing by food handlers

Evaluating

Nurses as primary caregivers can intervene in and positively affect a patient's outcome. By assessing the person at risk, identifying actual and potential health problems and needs, planning, and intervening to maintain a safe environment, the nurse can reduce a patient's potential for developing an infection.

Evaluation of the care plan determines whether the person's need for safety is being met effectively. Ongoing systematic evaluation is crucial for nurses who strive to maintain a secure environment for their patients as well as for themselves. If patient goals have been met and evaluative criteria have been satisfied, the patient will accomplish the following:

- Correctly use techniques of medical asepsis
- Identify health habits and lifestyle patterns that promote health
- State the signs and symptoms of an infection
- Identify unsafe situations in the home environment

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in evaluating the care plan, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

- How consistently do you personally adhere to asepsis and infection control practices? How would you respond to constructive/critical feedback from a peer regarding your aseptic technique?
- What value do you attach to involving the patient in infection control practices? How do you individualize the care for patients when so many guidelines, policies, and procedures dictate your care?
- Did your experience with asepsis and infection control techniques change your perspective on the necessity of guidelines? What plan do you have to stay abreast of evolving recommendations at the facility, local, state, national, and global levels?
- How did you prioritize the data you collected? What patterns in the data did you identify? What knowledge from your learning, personal experience and intuition did you use to make decisions and develop your plan of care regarding infection control and prevention practices?

Keeping up with the latest evidence-based practice guidelines can be challenging. Multi-resistant organisms, evolving patterns of transmission, and the spread of disease and infection outside of endemic areas require diligence on the part of the health care professional. Balancing the needs of your individual patients with these responsibilities requires mindfulness and intentionality.

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to ensure appropriate aseptic and infection control practices? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Skill 25-1 Performing Hand Hygiene Using Soap and Water (Handwashing)

DELEGATION CONSIDERATIONS

The application and use of hand hygiene using soap and water are appropriate for all health care providers.

EQUIPMENT

- Antimicrobial or nonantimicrobial soap (if in bar form, soap must be placed on a soap rack)
- Paper towels
- Moisturizing hand lotion or cream approved by health care facility (optional)

IMPLEMENTATION

ACTION	RATIONALE
1. Gather the necessary supplies. Stand in front of the sink. Do not allow your clothing to touch the sink during the washing procedure (Figure 1).	The sink is considered contaminated. Clothing may carry organisms from place to place.
2. Remove jewelry prior to patient contact, if possible, and secure in a safe place. A plain band may remain in place, based on facility policy.	Microorganisms may accumulate in settings of jewelry and underneath rings (CDC, 2019b), so it should not be worn during patient care. If jewelry was worn during care, it should be left on during handwashing.
3. Turn on water and adjust force (Figure 2). Regulate the temperature until the water is warm.	Water splashed from the contaminated sink will contaminate clothing. Warm water is more comfortable and is less likely to open pores and remove oils from the skin. Organisms can lodge in roughened and broken areas of chapped skin.

FIGURE 1. Standing in front of sink.

FIGURE 2. Turning on the water at the sink.

4. Wet the hands and wrist area. Keep hands lower than elbows to allow water to flow toward fingertips (Figure 3).	Water should flow from the cleaner area toward the more contaminated area. Hands are more contaminated than forearms.
5. Use about 1 teaspoon liquid soap from dispenser or rinse bar of soap and lather thoroughly, using a firm circular motion (Figure 4). Alternatively, use the amount of product recommended by the manufacturer. Cover all areas of hands with the soap product. If using bar soap, rinse soap bar again and return to soap rack without touching the rack.	Rinsing the soap before and after use removes the lather, which may contain microorganisms.

FIGURE 3. Wetting hands to the wrist.

FIGURE 4. Lathering hands with soap and rubbing with firm circular motion.

6. Continuing with firm rubbing and circular motions. Wash the palms and backs of the hands; each finger; the areas between the fingers (Figure 5); and the knuckles, wrists, and forearms. **Wash at least 1 inch above area of contamination.** If hands are not visibly soiled, wash to 1 inch above the wrists (Figure 6).

Friction caused by firm rubbing and circular motions helps to loosen dirt and organisms that can lodge between the fingers, in skin crevices of knuckles, on the palms and backs of the hands, and on the wrists and forearms. Cleaning less contaminated areas (forearms and wrists) after hands are clean prevents spreading microorganisms from the hands to the forearms and wrists.

FIGURE 5. Washing areas between fingers.

FIGURE 6. Washing to 1 inch above the wrist.

7. Continue this friction motion for at least 15 to 20 seconds.

Effective handwashing requires at least a 15- to 20-second scrub with plain soap or disinfectant and warm water (CDC, 2019b). Hands that are visibly soiled need a longer scrub.

8. Use fingernails of the opposite hand to clean under fingernails (Figure 7).

The area under nails has a high microorganism count, and organisms may remain under the nails, where they can grow and be spread to other people.

9. Rinse hands thoroughly under running water with water flowing toward fingertips (Figure 8).

Running water rinses microorganisms and dirt into the sink.

FIGURE 7. Using fingernails to clean under nails of opposite hand.

FIGURE 8. Rinsing hands under running water with water flowing toward fingertips.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

10. Pat hands dry with a paper towel, beginning with the fingers and moving upward toward forearms, and discard it immediately. Use another clean towel to turn off the faucet. Discard towel immediately without touching other clean hand.	Patting the skin dry prevents chapping. Dry hands first because they are considered the cleanest and least contaminated area. Turning the faucet off with a clean paper towel protects the clean hands from contact with a soiled surface.
11. Use moisturizing hand lotion or cream, as approved by facility policy.	Moisturizing hand lotion or cream helps to increase skin hydration to keep the skin soft and prevents dermatitis. It is best applied after patient care is complete, from a small, personal container, according to facility policy. Avoid use of unapproved lotions or creams because they can cause deterioration of gloves or decrease the efficacy of som providers should educate patients, family Follow facility policy.

DOCUMENTATION

The performance of handwashing is not generally documented.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

SPECIAL CONSIDERATIONS

General Considerations

- The use of gloves does not eliminate the need for hand hygiene.
- The use of hand hygiene does not eliminate the need for gloves.
- Ensure hands are dry before gloves are donned to decrease risk of dermatitis (Halm & Sandau, 2018).
- Hand hygiene performance by patients is an important intervention to reduce acquisition and transmission of HAIs (Srigley et al., 2020; Wong et al., 2020).
- Hand hygiene performance by family and non-family visitors to health care facilities is an important intervention to reduce acquisition and transmission of HAIs (Kim & Lee, 2019; Lary et al., 2020).
- Health care providers should educate patients, family, and nonfamily visitors on the importance of hand hygiene. Informed patients, families, and visitors have the ability to be better engaged as members of the health care team and are better able to advocate for themselves (Kim & Lee, 2019; Lary et al., 2020).
- Health care consumers in all settings should be encouraged to "speak up for clean hands" and advocate for the use of hand hygiene by health care providers, family, and friends (CDC, 2016a; Gesser-Edelsburg et al., 2020).
- Germs can live under artificial fingernails before and after hand hygiene interventions. Health care providers should not wear artificial fingernails or extensions when having direct contact with patients at high risk (e.g., patients in intensive care units or operating rooms) (CDC, 2019b).
- Health care providers should keep natural nail tips less than ¼-inch long (CDC, 2019b)

Community-Based Care Considerations

- Proper hand hygiene, including the use of alcohol-based hand sanitizers, is useful to reduce the risk of spread of microorganisms among family members and friends (CDC, 2016a). Patients, family members, and caregivers should be encouraged to perform hand hygiene, preferably by washing their hands; washing with soap and water is the best way to remove germs in most situations (CDC, 2020b). If soap and water are not readily available, alcohol-based hand sanitizer should be used (CDC, 2020b). Instruct patients, family members, and caregivers to perform hand hygiene (CDC, 2016a):
  - before preparing or eating food
  - before touching eyes, nose, or mouth
  - before and after changing wound dressings or bandages
  - after using the restroom
  - after blowing their nose, coughing, or sneezing
  - after touching hospital or other health care–setting surfaces such as doorknobs, phones, tables, and bed rails

Skill 25-2

Using Personal Protective Equipment

DELEGATION CONSIDERATIONS

The application and use of PPE are appropriate for all health care providers.

EQUIPMENT

- Gloves
- Mask (surgical or particulate respirator)
- Impervious gown
- Goggles or face shield (protective eye wear; does not include eyeglasses)

Note: Equipment for PPE may vary depending on level of precautions required and facility policy.

IMPLEMENTATION

ACTION	RATIONALE
1. Check medical record and plan of care for type of precautions and review precautions in infection control manual.	Mode of transmission of organism determines type of precautions required.
2. Plan nursing activities before entering patient's room.	Organization facilitates performance of task and adherence to precautions.
3. Provide instruction about precautions and use of PPE to patient, family members, caregivers, and visitors.	Explanation encourages cooperation of patient, family, and caregivers and reduces apprehension about precaution procedures.
 4. Perform hand hygiene.	Hand hygiene prevents the spread of microorganisms.
5. Put on gown, mask (surgical or particulate respirator), protective eyewear, and gloves based on the type of exposure anticipated and category of isolation precautions.	Use of PPE interrupts chain of infection and protects patient and nurse. Gown should protect all clothing and exposed skin on upper extremities. Gloves protect hands and wrists from microorganisms. Masks and particulate respirators protect wearer from direct contact with body fluids that may spray or splash; masks protect wearer from exposure to large-particle aerosols and particulate respirators protect wearer from inhalation of airborne droplet nuclei, and small-particle aerosols. Eyewear protects mucous membranes in the eye from splashes.
a. Put on the gown, with the opening in the back. Tie gown securely at neck and waist (Figure 1).	Gown should fully cover the torso from the neck to knees, arms to the end of wrists, and wrap around the back.
b. Put on the mask or respirator over your nose, mouth, and chin (Figure 2). Secure ties or elastic bands at the middle of the head and neck. Fit mask snug to face and below chin. Fit flexible band to nose bridge. If respirator is used, perform a fit check. Inhale: The respirator should collapse. Exhale: Air should not leak out.	Masks protect nurse or patient from droplet nuclei and large-particle aerosols. A mask must fit securely to provide protection.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 1. Tying gown at neck and waist.

FIGURE 2. Applying mask over nose, mouth, and chin.

c. Put on goggles (Figure 3). Place over eyes and adjust to fit. Alternatively, a face shield could be used (Figure 4).

Eyewear protects mucous membranes in the eye from splashes; it must fit securely to provide protection.

FIGURE 3. Putting on goggles.

FIGURE 4. Putting on face shield.

d. Put on clean disposable gloves. Extend gloves to cover the wrist of the gown (Figure 5).

Gloves protect hands and wrists from microorganisms.

FIGURE 5. Putting on gloves, ensuring gloves cover gown cuffs.

6. Identify the patient. Explain the procedure to the patient. Continue with patient care as appropriate.

Patient identification validates the correct patient and correct procedure. Discussion and explanation help allay anxiety and prepare the patient for what to expect.

Remove PPE

There are a variety of ways to remove PPE to achieve the goal of safe removal without contamination of clothes, skin, or mucous membranes (CDC, 2007;

updated 2019). Two methods are outlined here, based on CDC recommendations.

Method A

7. Remove PPE: Except for respirator, if worn, remove PPE before exiting the patient room or in an anteroom. **Remove respirator after leaving the patient's room and closing the door**.	Proper removal prevents contact with and the spread of microorganisms. Removing respirator outside the patient's room prevents contact with airborne microorganisms.
a. **Outside of gloves are contaminated.** If hands are contaminated during gown or glove removal, immediately perform hand hygiene.	Outside front of equipment is considered contaminated. Hand hygiene prevents transmission of microorganisms. The inside, outside back, and ties on head and back are considered clean, which are areas of PPE that are not likely to have been in contact with infectious organisms.
b. Grasp the palm area of one gloved hand with the opposite gloved hand and peel off first glove, turning the glove inside out as you pull it off (Figure 6). Hold the removed glove in the remaining gloved hand.	Outside of gloves are contaminated. This process contains the contaminated areas.
c. Slide fingers of ungloved hand under the remaining glove at the wrist, **taking care not to touch the outer surface of the glove** (Figure 7).	Ungloved hand is clean and should not touch contaminated areas.

FIGURE 6. Grasping the palm area of one glove and peeling off.

FIGURE 7. Sliding fingers of ungloved hand under the remaining glove at the wrist.

d. Peel off the second glove over the first glove, containing the first glove inside the other (Figure 8). Discard in appropriate container.	This process contains the outside, contaminated areas of gloves. Proper disposal prevents transmission of microorganisms.
e. To remove the goggles or face shield: **Outside of goggles or face shield is contaminated—do not touch.** If hands are contaminated during goggle or face shield removal, immediately perform hand hygiene. Handle by the headband or earpieces and remove from the back (Figure 9). Lift away from the face. **Do not touch the front of goggles or face shield.** Place in designated receptacle for reprocessing or in an appropriate waste container.	Outside of goggles or face shield is contaminated; do not touch. Hand hygiene prevents transmission of microorganisms. Handling by headband or earpieces and lifting away from face prevents transmission of microorganisms. Proper disposal prevents transmission of microorganisms.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 8. Peeling off the second glove, containing the first glove inside the other.

FIGURE 9. Removing goggles by grasping earpieces.

f. To remove gown: **Gown front and sleeves are contaminated.** If hands are contaminated during gown removal, immediately perform hand hygiene. Unfasten ties, if at the neck and back, taking care that sleeves of gown do not contact the body. Allow the gown to fall away from shoulders. **Touching only the inside of the gown**, pull away from the neck and shoulders (Figure 10). Keeping hands on the inner surface of the gown, pull gown from arms (Figure 11). Turn gown inside out. Fold or roll into a bundle (Figure 12) and discard in an appropriate waste container.

Gown front and sleeves are contaminated. Hand hygiene prevents transmission of microorganisms.
Touching only the inside of the gown and pulling it away from the torso prevents transmission of microorganisms.
This process contains the outside, contaminated areas of gown.
Proper disposal prevents transmission of microorganisms.

g. To remove mask or respirator: **Front of mask/respirator is contaminated—do not touch.** If hands are contaminated during mask/respirator removal, immediately perform hand hygiene. Grasp the bottom ties or elastic of the mask/respirator, then top ties or elastic and remove. **Do not touch the front of mask or respirator** (Figure 13). Discard in an appropriate waste container. If using a reusable respirator, save for future use in the designated area.

Front of mask or respirator is contaminated; do not touch. Not touching the front of the mask and proper disposal of the mask prevent transmission of microorganisms.

FIGURE 10. Touching only the inside of the gown, pull away from the neck and shoulders.

FIGURE 11. Keeping hands on the inner surface of the gown, pull gown from arms.

FIGURE 12. Turning gown inside out, rolling into a bundle.

FIGURE 13. Removing mask or respirator, grasping the neck ties or elastic, taking care to avoid touching the front.

Hand hygiene prevents spread of microorganisms.

8. Perform hand hygiene immediately after removing all PPE.

Remove PPE

There are a variety of ways to remove PPE to achieve the goal of safe removal without contamination of clothes, skin, or mucous membranes (CDC, 2007; update, 2019).

Front of gown and sleeves, including waist strings, are contaminated. Hand hygiene prevents transmission of microorganisms.
Front of gown and outside of gloves are contaminated. This process contains the outside, contaminated areas of gown.

Method B

7. To remove gown and gloves: **Gown front and sleeves and the outside of gloves are contaminated.** If hands are contaminated during gown and glove removal, immediately perform hand hygiene. **Touching outside of gown only with gloved hands**, grasp the gown in the front and pull away from the body, breaking the ties in the back (Figure 14). While removing the gown, fold or roll the gown inside-out into a bundle (Figure 15). As gown is being removed, peel off gloves at the same time, **only touching the inside of the gloves and gown with bare hands** (Figure 16). Discard gown and gloves in an appropriate waste container.

Proper disposal prevents transmission of microorganisms.
Outside of goggles or face shield is contaminated; do not touch. Hand hygiene prevents transmission of microorganisms.
Handling by headband or earpieces and lifting away from face prevents transmission of microorganisms. Proper disposal prevents transmission of microorganisms.
Front of mask or respirator is contaminated; do not touch. Not touching the front of the mask and proper disposal of the mask prevent transmission of microorganisms.
Hand hygiene prevents spread of microorganisms.

FIGURE 14. Grasping the outside of the front of gown and pulling away from the body.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 15. Rolling gown inside-out into a bundle.

FIGURE 16. Peeling off gloves as gown is being removed, touching only the inside of the gloves and gown.

8. To remove the goggles or face shield: **Outside of goggles or face shield is contaminated—do not touch.** If hands are contaminated during goggle or face shield removal, immediately perform hand hygiene. Grasp the headband or earpieces and remove from the back (Figure 17). Lift away from the face. **Do not touch the front of goggles or face shield.** Place in designated receptacle for reprocessing or in an appropriate waste container.

9. To remove mask or respirator: **Front of mask/respirator is contaminated—do not touch.** If hands are contaminated during mask/respirator removal, immediately perform hand hygiene. Grasp the bottom ties or elastic of the mask/respirator, then top ties or elastic, lift away from face, and remove (Figure 18). **Do not touch the front of mask or respirator.** Discard in an appropriate waste container. If using a reusable respirator, save for future use in the designated area.

FIGURE 17. Removing the goggles or face shield, grasping the headband or earpieces.

FIGURE 18. Removing the mask or respirator, grasping the bottom ties or elastic, and then the top ties or elastic.

10. Perform hand hygiene immediately after removing all PPE.

DOCUMENTATION

It is not usually necessary to document the use of specific articles of PPE or each application of PPE. However, document the implementation and continuation of specific transmission-based precautions as part of the patient's care.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *You did not realize the need for protective equipment at beginning of task:* Stop task and obtain appropriate protective wear.
- *You are accidentally exposed to blood and body fluids:* Stop task and immediately follow facility protocol for exposure, including reporting the exposure.

SPECIAL CONSIDERATIONS

Community-Based Care Considerations

- *Standard Precautions* are used for all patient care, based on risk assessment, and make use of common-sense practices and PPE to protect health care providers from infection and prevent the spread of infection from person to person (CDC, 2016b).
- Measures related to Respiratory Hygiene/Cough Etiquette should be implemented in community settings for any person with signs of illness including cough, congestion, rhinorrhea, or increased production of respiratory secretions (CDC, 2016b).

Skill 25-3 Preparing a Sterile Field and Adding Items to a Sterile Field

DELEGATION CONSIDERATIONS

Procedures requiring the use of a sterile field and other sterile items are not delegated to assistive personnel (AP). Depending on the state's nurse practice act and the organization's policies and procedures, these procedures may be delegated to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances, as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Sterile-wrapped drape
- Additional sterile supplies, such as dressings, containers, or solutions, as needed
- PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE
 1. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 2. Identify the patient. Explain the procedure to the patient.	Patient identification validates the correct patient and correct procedure. Discussion and explanation help allay anxiety and prepare the patient for what to expect.
Preparing a Sterile Field	
3. Check that the packaged sterile drape is dry and unopened. Also note expiration date, making sure that the date is still valid.	Moisture contaminates a sterile package. Expiration date indicates period that package remains sterile.
4. Select a work area that is waist level or higher.	Work area is within sight. Bacteria tend to settle, so there is less contamination above the waist.
For a Prepackaged Sterile Drape	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

a. Open the outer covering of the drape. Remove sterile drape, lifting it carefully by its corners. Hold away from body and above the waist and work surface.	Outer 1 inch (2.5 cm) of drape is considered contaminated. Any item touching this area is also considered contaminated.
b. Continue to hold only by the corners. Allow the drape to unfold, away from your body and any other surface (Figure 1).	Touching the outer side of the wrapper maintains the sterile field. Contact with any surface would contaminate the field.

FIGURE 1. Holding drape by corners and allowing it to unfold away from body and surfaces.

c. Position the drape on the work surface with the moisture-proof side down (Figure 2). This would be the shiny or blue side. Avoid touching any other surface or object with the drape. If any portion of the drape hangs off the work surface, that part of the drape is considered contaminated.	Moisture-proof side prevents contamination of the field if it becomes wet. The moisture penetrates the sterile cloth or paper and carries organisms by capillary action to contaminate the field. A wet field is considered contaminated if the surface immediately below it is not sterile.

For a Commercially Prepared Kit or Tray

a. Open the outside cover of the package (Figure 3) and remove the kit or tray. Place in the center of the work surface, with the topmost flap positioned on the far side of the package. Discard outside cover.	This allows sufficient room for sterile field.
b. Reach around the package and grasp the outer surface of the end of the topmost flap, holding no more than 1 inch from the border of the flap. Pull open away from the body, keeping the arm outstretched and away from the inside of the wrapper (Figure 4). Allow the wrapper to lie flat on the work surface.	This maintains sterility of inside of wrapper, which is to become the sterile field. Outer surface of the wrapper is considered unsterile. Outer 1-inch border of the wrapper is considered contaminated.
c. Reach around the package and grasp the outer surface of the first side flap, holding no more than 1 inch from the border of the flap. Pull open to the side of the package, keeping the arm outstretched and away from the inside of the wrapper (Figure 5). Allow the wrapper to lie flat on the work surface.	This maintains sterility of inside of wrapper, which is to become the sterile field. Outer surface of the wrapper is considered unsterile. Outer 1-inch border of the wrapper is considered contaminated.

FIGURE 2. Positioning drape on work surface with the moisture-proof side down.

FIGURE 3. Opening outside cover of package.

FIGURE 4. Pulling top flap open, away from body.

FIGURE 5. Pulling open the first side flap.

d. Reach around the package and grasp the outer surface of the remaining side flap, holding no more than 1 inch from the border of the flap. Pull open to the side of the package, keeping the arm outstretched and away from the inside of the wrapper (Figure 6). Allow the wrapper to lie flat on the work surface.	This maintains sterility of inside of wrapper, which is to become the sterile field. Outer surface of the wrapper is considered unsterile. Outer 1-inch border of the wrapper is considered contaminated.
e. Stand away from the package and work surface. Grasp the outer surface of the remaining flap closest to the body, holding not more than 1 inch from the border of the flap. Pull the flap back toward the body, keeping arm outstretched and away from the inside of the wrapper (Figure 7). Keep this hand in place. Use other hand to grasp the wrapper on the underside (the side that is down to the work surface). Position the wrapper so that when flat, edges are on the work surface, and do not hang down over sides of work surface (Figure 8). Allow the wrapper to lie flat on the work surface.	
f. The outer wrapper of the package has become a sterile field with the packaged supplies in the center (Figure 9). Do not touch or reach over the sterile field. Place additional sterile items on field as needed. Continue with the procedure as indicated.	Sterility of the field and contents are maintained.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 6. Pulling open the remaining side flap.

FIGURE 7. Pulling open flap closest to body.

FIGURE 8. Positioning wrapper on work surface.

FIGURE 9. Outside wrapper of package is now sterile field.

Adding Items to a Sterile Field

5. Place additional sterile items on field as needed.

To Add a Facility-Wrapped and Sterilized Item

a. Hold facility-wrapped item in the dominant hand, with top flap opening away from the body. With other hand, reach around the package and unfold top flap and both sides.	Only sterile surface and item are exposed before dropping onto sterile field.
b. Keep a secure hold on the item through the wrapper with the dominant hand. Grasp the remaining flap of the wrapper closest to the body, taking care not to touch the inner surface of the wrapper or the item. Pull the flap back toward the wrist, so the wrapper covers the hand and wrist.	Only sterile surface and item are exposed before dropping onto sterile field.
c. Grasp all the corners of the wrapper together with the nondominant hand and pull back toward wrist, covering hand and wrist. Hold in place.	Only sterile surface and item are exposed before dropping onto sterile field.
d. Hold the item 6 inches above the surface of the sterile field and drop onto the field. **Be careful to avoid touching the surface or other items or dropping any item onto the 1-inch border**.	This prevents contamination of the field and inadvertent dropping of the sterile item too close to the edge or off the field. Any items landing on the 1-inch border are considered contaminated.

To Add a Commercially Wrapped and Sterilized Item

a. Depending on the type of package, hold package in one hand. Pull back top cover with other hand. Alternatively, carefully peel the edges apart using both hands (Figure 10).	Contents remain uncontaminated by hands.
b. After top cover or edges are partially separated,	This prevents contamination of the field and inadvertent

hold the item 6 inches above the surface of the sterile field. Continue opening the package and drop the item onto the field (Figure 11). **Be careful to avoid touching the surface or other items or dropping an item onto the 1-inch border.**

dropping of the sterile item too close to the edge or off the field. Any items landing on the 1-inch border are considered contaminated.

FIGURE 10. Carefully peeling edges apart.

FIGURE 11. Dropping sterile item onto sterile field.

c. Discard wrapper.	A neat work area promotes proper technique and avoids inadvertent contamination of the field.
To Add a Sterile Solution	
a. Obtain appropriate solution and check expiration date.	Once opened, label any bottles with date and time. Solution may be kept for use for 24 hours once opened.
b. Open solution container according to directions and **place cap on table away from the field with edges up** (Figure 12).	Sterility of inside cap is maintained.
c. Hold bottle outside the edge of the sterile field with the label side facing the palm of your hand and prepare to pour from a height of 4 to 6 inches (10 to 15 cm). **Do not touch the tip of the bottle to the sterile container or field.**	Label remains dry, and solution may be poured without reaching across sterile field. Minimal splashing occurs from that height. Accidentally touching the tip of the bottle to a container or dressing contaminates them both.
d. Pour required amount of solution steadily into sterile container previously added to the sterile field and positioned at side of sterile field or onto dressings (Figure 13). **Avoid splashing any liquid.**	A steady stream minimizes the risk of splashing; moisture contaminates sterile field.

FIGURE 12. Opening bottle of sterile solution and placing cap on table with edges up.

FIGURE 13. Pouring solution into sterile container.

6. Continue with procedure as indicated.

Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

7. When procedure is completed, remove PPE, if used. Perform hand hygiene.

DOCUMENTATION

It is not usually necessary to document the addition of sterile items to a sterile field. However, document the use of performing sterile technique for any procedure.

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- A part of the sterile field becomes contaminated: *When any portion of the sterile field becomes contaminated, discard the sterile field and any items on the field and start over.*
- You realize a supply is missing after setting up the sterile field: *Call for help. Do not leave the sterile field unattended. If you are unable to see the sterile field at all times, it is considered contaminated.*
- The patient touches the sterile field: *If the patient touches the sterile field, discard the supplies and prepare a new sterile field. If the patient is confused, have someone assist by holding the patient's hands and/or reinforcing what is happening.*

Skill 25-4 Putting on Sterile Gloves and Removing Soiled Gloves

DELEGATION CONSIDERATIONS

Procedures requiring the use of sterile gloves and other sterile items are not delegated to assistive personnel (AP). Depending on the state's nurse practice act and the organization's policies and procedures, these procedures may be delegated to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances, as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Sterile gloves of the appropriate size
- PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE
 1. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 2. Identify the patient. Explain the procedure to the patient.	Patient identification validates the correct patient and correct procedure. Discussion and explanation help allay anxiety and prepare the patient for what to expect.
3. Check that the sterile glove package is dry and unopened. Also note expiration date, making sure that the date is still valid.	Moisture contaminates a sterile package. Expiration date indicates the period that the package remains sterile.
4. Place sterile glove package on clean, dry surface at or above your waist.	Moisture could contaminate the sterile gloves. Any sterile object held below the waist is considered contaminated.
5. Open the outside wrapper by carefully peeling the top layer back (Figure 1). Remove inner package, handling only the outside of it.	This maintains sterility of gloves in inner packet.
6. Place the inner package on the work surface with the	Allows for ease of glove application.

side labeled “cuff end” closest to the body.

7. Carefully open the inner package. Fold open the top flap, then the bottom and sides (Figure 2). **Do not touch the inner surface of the package or the gloves.**

The inner surface of the package is considered sterile. The outer 1-inch border of the inner package is considered contaminated. The sterile gloves are exposed with the cuff end closest to the nurse.

FIGURE 1. Pulling top layer of outside wrapper back.

FIGURE 2. Folding back side flaps.

8. With the thumb and forefinger of the nondominant hand, grasp the folded cuff of the glove for the dominant hand, touching only the exposed inside of the glove (Figure 3).

Unsterile hand touches only inside of glove. Outside remains sterile.

9. Keeping the hands above the waistline, lift and hold the glove up and off the inner package with fingers down (Figure 4). **Do not let it touch any unsterile object.**

Glove is contaminated if it touches any unsterile objects.

10. Carefully insert dominant hand palm up into glove (Figure 5) and pull glove on. Leave the cuff folded until the opposite hand is gloved.

Attempting to turn upward with unsterile hand may result in contamination of sterile glove.

11. Hold the thumb of the gloved hand outward. Place the fingers of the gloved hand inside the cuff of the remaining glove (Figure 6). Lift it from the wrapper, taking care not to touch anything with the gloves or hands.

Thumb is less likely to become contaminated if held outward. Sterile surface touching sterile surface prevents contamination.

FIGURE 3. Grasping cuff of glove for dominant hand.

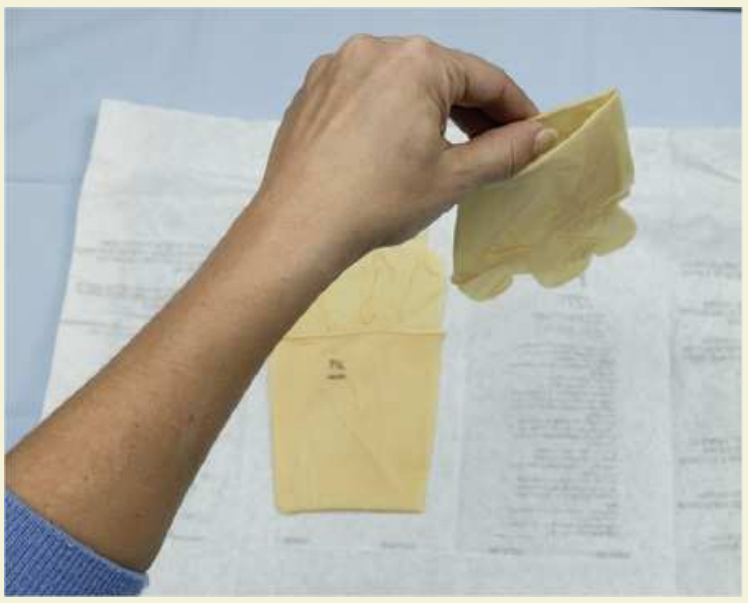

FIGURE 4. Lifting glove from package.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 5. Inserting dominant hand into glove.

FIGURE 6. Sliding fingers under cuff of glove for nondominant hand.

12. Carefully insert nondominant hand into glove. Pull the glove on, taking care that the skin does not touch any of the outer surfaces of the gloves.
    Sterile surface touching sterile surface prevents contamination.

13. Slide the fingers of one hand under the cuff of the other and fully extend the cuff down the arm, **touching only the sterile outside of the glove** (Figure 7). Repeat for the remaining hand.
    Sterile surface touching sterile surface prevents contamination.

14. Adjust gloves on both hands, if necessary, **touching only sterile areas with other sterile areas** (Figure 8).
    Sterile surface touching sterile surface prevents contamination.

FIGURE 7. Sliding fingers of one hand under cuff of other hand and extending cuff down the arm.

FIGURE 8. Adjusting gloves as necessary.

15. Continue with procedure as indicated.

Removing Soiled Gloves

16. **Outside of gloves is contaminated.** If hands are contaminated during gown or glove removal, immediately perform hand hygiene. Grasp the palm area of one gloved hand with the opposite gloved hand. Remove it by pulling it off, inverting it as it is pulled, keeping the contaminated area on the inside (Figure 9). Hold the removed glove in the remaining gloved hand.
    Hand hygiene prevents the spread of microorganisms. Contaminated area does not come in contact with hands or wrists.

FIGURE 9. Inverting glove as it is removed.

17. Slide fingers of ungloved hand between the remaining glove and the wrist (Figure 10). **Take care to avoid touching the outside surface of the glove.** Remove it by pulling second glove over the first glove, inverting it as it is pulled, keeping the contaminated area on the inside, and securing the first glove inside the second (Figure 11).

FIGURE 10. Sliding fingers of ungloved hand inside remaining glove.

FIGURE 11. Inverting glove as it is removed, securing first glove inside it.

Contaminated area does not come in contact with hands or wrists.

18. Discard gloves in appropriate container. Remove additional PPE, if used. Perform hand hygiene.

Proper removal and disposal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms.

DOCUMENTATION

It is not usually necessary to document the application of sterile gloves and removal. However, document the use of sterile technique for any procedure performed using sterile technique.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *Contamination occurs during application of the sterile gloves:* Discard gloves and open new package of sterile gloves.
- *A hole or tear is noticed in one of the gloves:* Discard gloves and open a new package of sterile gloves.
- *A hole or tear is noticed in one of the gloves during the procedure:* Stop procedure. Remove damaged gloves. Perform hand hygiene and put on new sterile gloves.
- *The patient touches the nurse's hand:* If the patient touches your hands and nothing else, you may remove the contaminated gloves and put on new sterile gloves. It may be a good idea to bring two pairs of sterile gloves into the room, depending on facility policy, so that you will not have to leave the procedure to get a new pair.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- If the patient touches the sterile field, discard the supplies and prepare a new sterile field. If the patient is confused, have someone assist you by holding the patient's hands or reinforcing what is happening.
- *Patient has a latex allergy:* Obtain latex-free sterile gloves.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. A nurse cannot help but notice that whenever a particular surgeon makes rounds, he ignores basic principles of asepsis. He moves from one patient to another, touching dressings without washing his hands between patients. He is also inconsistent in his practice of sterile technique. You have anecdotal information that leads you to suspect that there is a higher rate of postoperative infection among his patients. What do you do?

. A friend who is a nursing student always wears gloves when doing anything for ill patients. You are more selective in your use of gloves. She tells you that you are a fool for "taking chances" because you never know what you may pick up and bring home. Is this a matter of personal preference? What about human touch? Is one position more consistent with good nursing? Are your instructors consistent in how they respond to these questions?

PRACTICING FOR NCLEX

. A nurse is changing a patient's bed linens after drainage from an infected abdominal wound leaked. Which nursing action reflects proper use of medical asepsis?

a. Carrying soiled bed linens close to the body to prevent spreading microorganisms into the air
b. Placing soiled bed linens and hospital gowns on the floor when making the bed
c. Moving the patient table away from the body when wiping it off
d. Cleaning the most soiled items at the bedside first, followed by cleaner items

. An outbreak of measles has occurred at the local elementary school. The parents of a child in the prodromal phase of the illness are told the child should stay home until well. What is important for the nurse to teach the parents about the prodromal phase?

a. The organisms enter the body and multiply while the patient is asymptomatic.
b. A person typically has vague, nonspecific symptoms and is highly contagious.
c. The presence of infection-specific signs and symptoms develop, manifesting as local or systemic responses.
d. The signs and symptoms of the illness disappear, and the person returns to their preillness state.

. A nursing unit has multiple patients with MRSA infections requiring contact isolation. In which situations is it appropriate for the nurses to use an alcohol-based hand sanitizer to decontaminate their hands? Select all that apply.

a. Before providing a bed bath
b. Having visibly soiled hands after patient contact
c. Removing gloves after patient care
d. Inserting a urinary catheter
e. Assisting with a surgical placement of a cardiac stent
f. Removing old magazines from a patient's table

. A nursing student is performing hand hygiene after providing care to a patient who is in isolation for *C. diff* related to antibiotic therapy. Which actions by the nursing student will the primary nurse need to correct? Select all that apply.

a. Removing all jewelry including a platinum wedding band
b. Decontaminating the hands with an alcohol-based hand sanitizer
c. Using approximately 1 teaspoon of liquid soap
d. Keeping hands higher than elbows when placing under the faucet
e. Using friction motion when washing for at least 20 seconds
f. Rinsing thoroughly with water flowing toward the fingertips

. When performing a dressing change requiring surgical asepsis, a nurse opens sterile supplies and dons sterile gloves. What additional action by the nurse is appropriate?

a. Avoiding splashing while pouring irrigant onto the sterile field
b. Covering the nose and mouth with gloved hands if a sneeze is imminent
c. Using forceps soaked in a disinfectant to place dressings on the sterile field
d. Considering the outer 1 inch of the sterile field sterile

. The nurse on a medical-surgical unit is admitting a patient with a diagnosis of active tuberculosis. Which infection control precautions will the nurse put in place?

a. Wearing sterile gloves for patients with visible body fluids

b. Placing the patient on airborne precautions
c. Wearing an N95 respirator mask when in the room
d. Placing the patient in a single-occupancy room
e. Ensuring the room provides positive pressure
f. Restricting visitors for the duration of the patient's stay

. Nursing students enrolled in a medical-surgical nursing course are learning about infection control measures. They have learned that nurses use droplet precautions for patients with which infections? Select all that apply.

a. Rubella
b. Herpes simplex
c. Varicella
d. Tuberculosis
e. MRSA
f. Adenovirus

. A nurse and health care provider are preparing for insertion of a central venous catheter when the patient accidentally touches the sterile field. What action will the nurse take next?

a. Ask another nurse to hold the patient's hand and continue setting up the field
b. Remove any objects the patient touched and resume setting up the sterile field
c. Have someone hold the patient's hand, discard the supplies, and prepare a new sterile field
d. No action since the patient has touched their own sterile field

. When performing sterile wound irrigation and dressing change for a postoperative patient, a new graduate nurse creates a sterile field. Which actions require correction by the preceptor? Select all that apply.

a. Placing the bottle cap for the irrigating solution off the sterile field with the edges down
b. Holding the bottle of irrigating solution inside the edge of the sterile field
c. Applying the second sterile glove by lifting it from beneath the cuff with the thumb held away from the glove
d. Pouring the irrigating solution into a sterile container from a height of 4 to 6 inches (10 to 15 cm)
e. Opening packages of sterile gauze dressings, prior to applying sterile gloves

. A nurse has finished providing care for a patient in contact isolation for a MRSA infection. Place the steps the nurse should follow to remove PPE in the correct order.

a. Untie gown at the front waist
b. Remove mask
c. Remove gloves
d. Remove gown
e. Remove goggles

. A nurse administering an injection to a patient who tested positive for HIV sustains a needlestick. What action should the nurse take first?

a. Report the incident to the nurse manager and file an injury report
b. Wash the exposed area with warm water and soap
c. Consent to postexposure prophylaxis (PEP) at the appropriate time
d. Set up counseling sessions regarding safe practice to protect self

. During morning huddle, a nurse manager and some nurses are identifying patients on the unit who are at risk for hospital-acquired infections (HAIs). Which patients will the nurses identify? Select all that apply.

a. Smoker, two packs of cigarettes daily
b. White blood cell count of 2,000/mm^3
c. Indwelling urinary catheter in place
d. Vegetarian and slightly underweight
e. Central venous catheter present
f. Postoperative colostomy

. A nurse is caring for a patient who is incontinent of stool and has developed a stage 3 pressure wound on the buttocks. What intervention will the nurse set as the priority of care?

a. Increasing nutrition
b. Promoting mobility
c. Managing chronic pain
d. Preventing infection

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

. A home health nurse teaches a patient to a change the dressing for a chronic venous stasis ulcer using clean technique. Which principle of asepsis will the nurse consider when preparing the teaching plan?

a. The nurse chooses clean or sterile technique based on personal preference.
b. The use of clean technique is considered safe in the home setting.
c. Surgical asepsis is the safest method to use in a home setting.
d. The patient can use clean technique; their partner must wear sterile gloves.

. When bathing a patient with *C. diff* infection, the nurse wears personal protective equipment (PPE). Which additional intervention promotes safe, effective care?

a. Donning PPE after entering the patient room
b. Bathing the perianal area last
c. Personalizing care by substituting glasses for goggles
d. Removing PPE after bathing the patient to talk with them in the room

. A nurse is preparing to admit a patient with urinary sepsis related to vancomycin-resistant enterococci (VRE). While awaiting the patient's arrival, which of these actions will the nurse take?

a. Prepare a negative-pressure room
b. Ask the AP to get a supply of protective gowns
c. Post a sign that visitors must wear a mask
d. Obtain sterile gloves for personal care

ANSWERS WITH RATIONALES

. **c.** According to the principles of medical asepsis, the nurse should move equipment and soiled items away from the body to prevent contaminated particles from settling on the hair, face, or uniform. The nurse should not put soiled items on the floor, as it is highly contaminated. The nurse should also clean the least soiled areas first, then move to the more soiled ones to prevent contamination.

. **b.** During the prodromal stage, the person has vague signs and symptoms, such as fatigue and a low-grade fever. There are no obvious symptoms of infection during the incubation period, and symptoms are more specific and apparent during the full stage of illness, disappearing in the convalescent period.

. **a, c, d, f.** An alcohol-based handrub is used in the following situations: before direct contact with patients; after direct contact with patient skin; after contact with body fluids *if hands are not visibly soiled;* after removing gloves; before inserting urinary catheters, peripheral vascular catheters, or invasive devices *not requiring surgical placement;* before donning sterile gloves prior to an invasive procedure; when moving from a contaminated body site to a clean body site; and after contact with objects contaminated by the patient. It is essential to note that handrubs are not appropriate for use after caring for a patient with *C. diff* infection.

. **b, d.** After caring for patients with *C. diff* infection, proper handwashing includes using soap and water, then rinsing thoroughly with water flowing toward fingertips. Proper hand hygiene permits a plain wedding band to be worn; other jewelry is removed. The nurse uses about 1 teaspoon (5 mL) of liquid soap, using friction motion for at least 20 seconds, washing to 1 inch above the wrists using friction.

. **d.** Considering the outer inch of a sterile field as contaminated is a principle of surgical asepsis. Moisture, such as from splashes contaminates the sterile field, and sneezing would contaminate the sterile gloves. Forceps soaked in disinfectant are not considered sterile.

. **b, c, d.** Airborne precautions are used for patients who have infections with small particles that spread through the air, for example, tuberculosis, varicella, and rubeola. An N95 respirator mask is worn and the patient placed in a private room, preferably with negative air pressure. Sterile gloves are used for procedures requiring surgical asepsis. Standard precautions are for all patient care when contact with blood or body fluids, nonintact skin, and mucous membranes are likely. Visitors must wear PPE, including a mask.

. **a, b, f.** Rubella, diphtheria, and adenovirus infection are illnesses transmitted by large-droplet particles; droplet precautions and standard precautions are indicated. Airborne precautions refer to small, infectious particles spread through the air; for example, tuberculosis, varicella, and rubeola. Contact precautions are used for patients who are infected or colonized by a multidrug-resistant organism (MDRO), such as MRSA.

. **c.** If a patient touches a sterile field, the nurse should discard all supplies and prepare a new sterile field. If the patient is restless or confused, the nurse obtains an assistant to hold the patient's hands and explain what is happening.

. **d, e.** To add a sterile solution to a sterile field, the nurse opens the solution container according to directions and places the cap on the table away from the field with the edges up. The nurse then holds the bottle outside the edge of the sterile field with the label side facing the palm of the hand and pours from a height of 4 to 6 inches (10 to 15 cm) to prevent splashing.

. **a, c, e, d, b.** If an impervious gown has been tied in front of the body at the waist, the nurse should untie the waist

strings before removing gloves. Gloves are removed first because they are most likely to be contaminated, followed by the goggles, gown, and mask. Hands should be washed thoroughly after the equipment has been removed and before leaving the room.

. **b.** When a needlestick injury occurs, the nurse should wash the affected area immediately with warm water and soap, report the incident to the nurse manager or appropriate person and complete an injury report, consent to and await the results of blood tests, consent to PEP, and attend counseling sessions regarding safe practice to protect self and others.

. **b, c, e, f.** Leukopenia (low white blood cell count), indwelling urinary catheters, central venous catheters, and surgeries in which the wound is classified as dirty have been implicated in most HAIs. Cigarette smoking and a vegetarian diet have not been implicated as risk factors for HAIs.

. **d.** The priority in this situation is to prevent infection through contamination of the wound by stool. The other actions may be taken as needed, after infection prevention is addressed.

. **b.** Medical asepsis, or clean technique, involves procedures and practices that reduce the number and transfer of pathogens. This is usually recommended in the home setting, where the patient's environment is more controlled. Injections require surgical asepsis. The patient and partner share the same home; medical asepsis is appropriate.

. **b.** When using PPE, the nurse should work from clean areas to soiled ones, don PPE before entering the patient room, always use goggles instead of personal glasses, and remove PPE in the doorway or anteroom just before exiting.

. **b.** VRE is spread via contact with the feces, urine, or blood of an infected or colonized person. Contact precautions, meticulous hand hygiene, reducing the use of invasive devices, environmental cleaning, and decolonizing high-risk patients are indicated. Some institutions have discontinued using contact precautions and use standard precautions, with no significant change in the incidence of MRSA or VRE.

26

Vital Signs

Noah Shoolin

Noah is a 2-year-old who is brought to the emergency department by his mother. When the nurse attempts to obtain a tympanic temperature, the child begins to scream uncontrollably, crying and pushing the device away from his ear.

Tomas Esposito

Tomas is a middle-aged man admitted to the hospital. He is placed in a private room with transmission-based infection control precautions, requiring staff to put on a gown and gloves when entering the room. A morning assessment, including vital signs, is needed.

Doretha Renfrow

Doretha brings her 65-year-old husband, who is overweight and has high blood pressure, to the clinic for evaluation. Mrs. Renfrow states, “I really would like to learn how to take my husband’s blood pressure so that I can keep track of his progress. Can you teach me how to do it?”

Lippincott DocuCare Additional patient scenarios available in ***Lippincott DocuCare*.**

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Explain the physiologic processes involved in homeostatic regulation of temperature, pulse, respirations, and blood pressure.
. Compare and contrast factors that increase or decrease body temperature, pulse, respirations, and blood pressure.
. Identify sites for assessing temperature, pulse, and blood pressure.
. Assess temperature, pulse, respirations, and blood pressure accurately.
. Demonstrate knowledge of the normal ranges for temperature, pulse, respirations, and blood pressure across the life span.
. Provide information to patients about measuring temperature, pulse, and blood pressure at home.

temperature
vital signs

Vital signs are indicators of physiologic functioning and reflect the health status of a person. Vital signs include a person's temperature, pulse, respiration, and blood pressure (abbreviated as T, P, R, BP). Pain assessment is often included along with measurement of vital signs and is discussed in Chapter 36. Pulse oximetry, the noninvasive measurement of arterial oxyhemoglobin saturation, is also often included with the measurement of vital signs and is discussed in Chapter 40.

Assessing vital signs as part of a nursing assessment is an important component of care in all health care settings. Nurses assess vital signs in a wide variety of instances, and compare findings with accepted normal values, the patient's usual patterns, with consideration to potential variations related to specific health conditions, illnesses and complications, medications, environmental factors, and therapies. Monitoring and analysis of the significance vital signs are important nursing responsibilities and are crucial to identifying changes in patient status (Dalton et al., 2018). Monitoring and evaluation of trends in intermittently measured vital signs is an important part of early identification of risk for a serious adverse event, contributing to timely intervention and improved patient outcomes (Brekke et al., 2019; Churpek et al., 2016).

Examples of appropriate times to measure vital signs include, but are not limited to, screenings at health fairs and clinics, in the home, upon admission to a health care setting, when medications are given that affect cardiac rate and rhythm, before and after invasive diagnostic and surgical procedures, and in emergency situations. Nurses obtain vital signs as often as a patient's condition requires such assessment, prioritizing, and adapting assessment of vital signs to address the patient's unique situation (Box 26-1). Frequency of assessment should be based on the patient's medical diagnosis, comorbidities, types of treatments and medications received, the patient's level of acuity and risk for complications, trends in the patient's vital signs, prescribed interventions, and facility policies (Burchill et al., 2015). Identification of a change in data related to assessment of vital signs is a crucial part of determining and recognizing deterioration in the status of a patient (Dalton et al., 2018). A patient's vital signs, along with oxygen saturation level (see Chapter 40), have been identified as the best indicators of cardiopulmonary arrest, unplanned intensive care unit (ICU) admission, and unexpected death (Malycha et al., 2019; Souza et al., 2019).

Box 26-1 When to Assess Vital Signs

- On admission to any health care facility or institution
- Based on facility or institutional policies and procedures
- Any time there is a change in the patient's condition
- Any time there is a loss of consciousness
- Before and after any surgical or invasive diagnostic procedure
- Before and after activity that may increase risk, such as ambulation after surgery
- Before administering medications that affect cardiovascular and respiratory function

In addition, institutional and facility policies provide guidance as to when and how frequently vital signs are assessed. For example, vital signs are assessed at 4-hour intervals, at a minimum, in hospitalized patients with elevated temperatures, with high or low blood pressures, with changes in pulse rate or rhythm, or with respiratory difficulty. In critical care settings, technologically advanced devices are used to continually monitor patients' vital signs. Regulations require monthly vital sign measurements in long-term care residents, but for residents classified as Medicare A (meaning they have been discharged from the hospital and now Medicare is paying for their stay to receive skilled nursing care) vital signs are taken daily. In the home and in some self-care and psychiatric units, assessments may be made only as frequently as the nurse judges necessary.

Although vital sign assessment may be delegated to other health care personnel when the condition of the patient is stable, it is the nurse's responsibility to ensure the accuracy of the data, interpret vital sign findings, and report abnormal findings. Principles of delegation should be followed. (Delegation is discussed in Chapters 10 and 18.) If a patient has abnormal or unusual physical signs or symptoms (e.g., chest pain or dizziness) or has unexpected changes in vital signs, the nurse should validate the findings and further assess the patient. See the accompanying Reflective Practice box for an example. The nurse should know the normal variations in vital signs that occur at various ages as listed in Table 26-1 and understand potential variations related to specific health conditions and illnesses.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

At clinical 2 weeks ago, I had four patients for the first time, and I was very busy. One of my patients, Tomas Esposito, required transmission-based infection control precautions. So, every time I entered his room, I had to put on a gown and gloves. It was getting to be late in the morning and I still had not completed this patient's full assessment, including his vital signs. Upon entering the patient's room, I discovered that the separate stethoscope usually found in isolation rooms was not there. As a result, I had to remove my gown and gloves and go find the nurse to help me locate the stethoscope. Ultimately, the nurse had to get me a new isolation stethoscope set and put it together for me. Unfortunately, these stethoscopes are often poor in quality.

I went back to the patient's room and put on a new gown and gloves. By this time, Mr. Esposito was very irritable, and just wanted me to do the assessment quickly and leave him alone. I attempted to listen to measure his blood pressure, but I couldn't hear any sound after opening the valve on the blood pressure cuff. I played with the stethoscope for a few minutes and tried again, but I still couldn't hear anything. My patient kept telling me to leave him alone. Being a fourth-year nursing student and self-sufficient in doing the basic patient assessment, I felt stupid going to get the nurse or my instructor and telling her I couldn't obtain a blood pressure. I was really pressed for time and now was faced with a critical decision.

Thinking Outside the Box: Possible Courses of Action

- Remove my gown and gloves, get my instructor and the nurse and tell them that I was unable to hear any sounds to obtain a blood pressure measurement, and request their assistance.
- Leave the patient alone as he requested, saving precious time, pretending that I completed vital signs and his assessment, and charting the same findings as the previous shift's assessment.
- Explain to the nurse that the patient wasn't cooperating and ask her to do the blood pressure and assessment without my instructor knowing about it.
- Try to complete the vital signs and assessment using my own stethoscope and risk transmission of potentially infectious microorganisms to other patients on the unit.

Evaluating a Good Outcome: How Do I Define Success?

- Patient receives the highest quality of care.
- Professional integrity of all health care team members involved is maintained.
- All documented information is accurate.
- Professional, ethical, and legal principles are maintained.

Personal Learning: Here's to the Future!

Luckily, my conscience and my desire to always give the best care to my patients pushed me to the right decision. I took the time to remove my gown and gloves and went to find my instructor and the nurse. I told the nurse that I was having trouble hearing the patient's blood pressure. She was very understanding and came to the room with me and tried herself. Upon further investigation, we found that the problem was a broken stethoscope, not my incompetence to complete an assessment. After assessing the patient with a properly functioning stethoscope, I obtained his blood pressure, and also found expiratory wheezing and documented it. This finding provided a clue that I should probably keep a very close eye on this patient. Mr. Esposito ended up experiencing increasing difficulty breathing and his oxygen saturation levels began to drop. As a result, I realized just how important the initial assessment is when caring for a patient throughout the day. Hopefully, the lesson about how important it is to do the "right" thing for the patient will stick with me forever.

Catherine Barrell, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills, and attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Mr. Esposito?

Patient-Centered Care: What information should be communicated to the patient about the care provided? How could you involve Mr. Esposito as a partner in coordinating his care to minimize frustration

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

on the part of the patient and student? What might you have done to prevent the numerous trips in and out of the patient's room?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to improve to ensure that you function as a member of the patient-care team and to obtain assistance when needed? How should you follow up regarding the defective equipment?

Safety/Evidence-Based Practice: What might you have done to determine whether the stethoscope was functioning properly? How do you think your time management and organizational skills affect the situation? What evidence in nursing literature provides guidance for decision making regarding infection control?

Informatics: Can you identify the essential information that must be available in Mr. Esposito's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation?

Table 26-1 Age-Related Variations in Normal Vital Signs

AGE	TEMPERATURE °F °C	PULSE beats/min	RESPIRATIONS breaths/min	BLOOD PRESSURE mm Hg
Newborns	97.2–99.9 36.2–37.7	95–170	30–60	60–70/40
Infants	96–99.7 35.6–37.6	85–170	30–50	85/37
Toddler	96–99 35.6–37.2	70–150	20–40	88/42
Child	96–99 35.6–37.2	65–130	15–25	95/57
Adolescent	96.4–99.5 35.8–37.5	60–115	12–20	102/60
Adult	96.4–99.5 35.8–37.5	60–100	12–20	<120/80

Recall **Tomas Esposito**, the patient requiring initial assessment described in the Reflective Practice display. The nurse's inability to auscultate heart and lung sounds would be an important finding that requires additional assessment. The nurse would need to evaluate these findings in conjunction with the patient's other vital signs and symptoms.

The skills of assessing each of the vital signs, with rationale for each action, and a discussion of normal and abnormal findings are presented in this chapter. See Chapter 27 for additional information about vital signs and health assessment.

TEMPERATURE

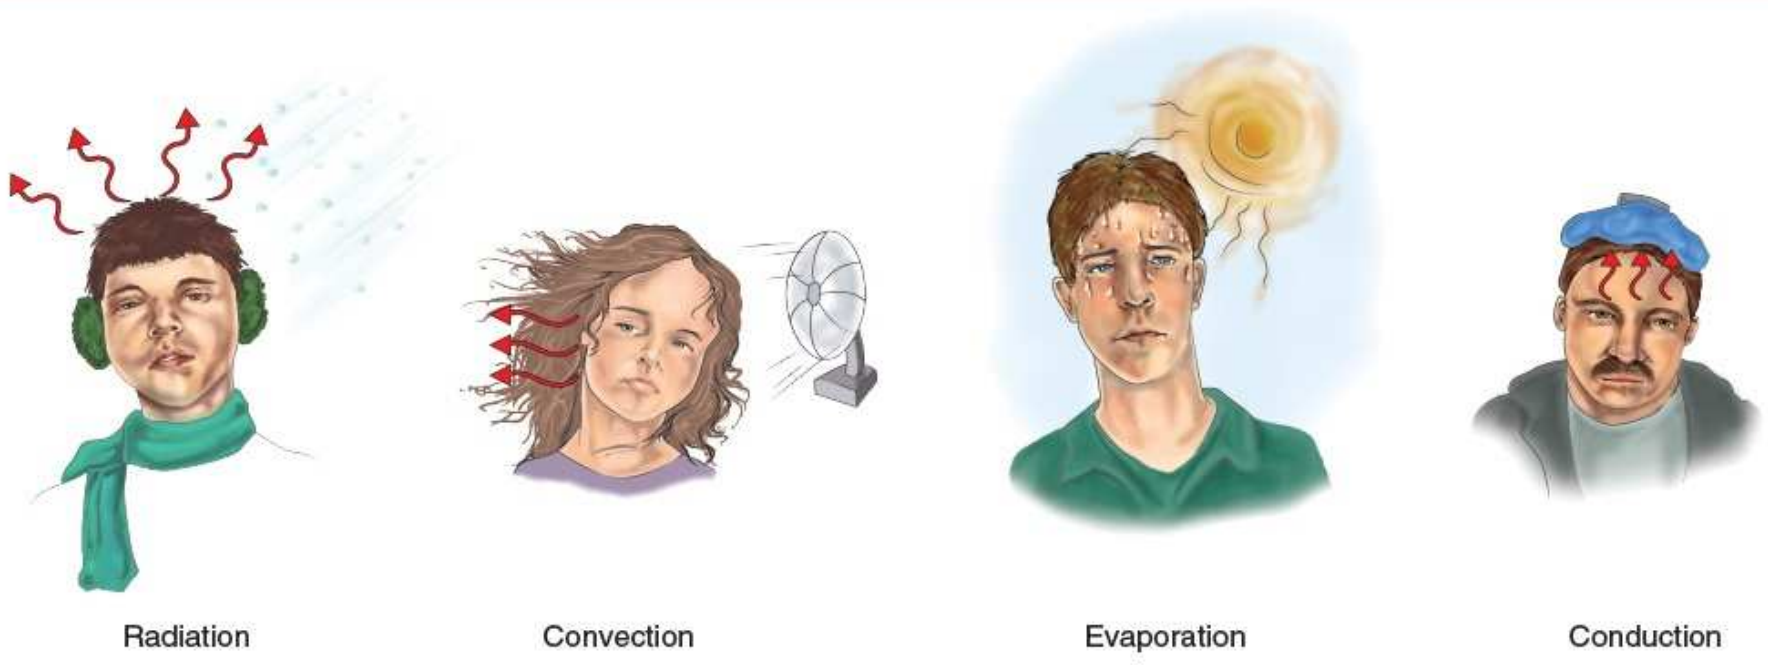
Body **temperature** is the difference between the amount of heat produced by the body and the amount of heat lost to the environment measured in degrees. Heat is generated by metabolic processes in the core tissues of the body, transferred to the skin surface by the circulating blood, and then dissipated to the environment. Core body temperature (intracranial, intrathoracic, and intraabdominal) is higher than surface body temperature. Normal body temperature ranges from 96.7° to 100.5°F (35.9° to 38°C), depending on the route used for measurement (Jensen, 2019).

There are individual variations of these temperatures as well as variations related to age, biologic sex, physical activity, state of health, and environmental temperatures. Body temperature also varies during the day, with temperatures being lowest in the early morning and highest in the late afternoon (Boron & Boulpaep, 2016, as cited in Norris, 2019).

Physiology of Body Temperature

The core body temperature of a healthy person is maintained within a fairly constant range by the thermoregulatory set point of the thermoregulatory center in the hypothalamus. This center receives messages from cold and warm thermal receptors located throughout the body, compares that information with its temperature set point, and initiates responses to either produce or conserve body heat or to increase heat loss.

Heat Production



The primary source of heat in the body is metabolism, with heat produced as a by-product of metabolic activities that generate energy for cellular functions. Various mechanisms increase body metabolism, including hormones and exercise. When additional heat is required to maintain balance, epinephrine, and norepinephrine (sympathetic neurotransmitters) are released to rapidly alter metabolism so that energy production decreases and heat production increases. Thyroid hormone, produced by the thyroid gland, also increases metabolism and heat production, but over a much longer period. Shivering, a response that increases the production of heat, is initiated by the hypothalamus and results in muscle tremors, causing the production of heat. In addition, the contraction of pilomotor muscles of the skin, as occurs with shivering, causes piloerection, or "goose bumps," and reduces the surface area of skin available for heat loss. Physical exertion increases heat production through muscle movements.

Heat Loss

The skin is the primary site of heat loss. The circulating blood brings heat to the small connections between the arterioles and the venules, which lie directly below the skin's surface. These connections, called arteriovenous shunts, may remain open to allow heat to dissipate (e.g., during exercise in hot environmental temperatures) to the skin and then to the external environment, or they may close and retain heat in the body (e.g., when the body is exposed to cold environmental temperatures). The sympathetic nervous system controls the opening and closing of the shunts in response to changes in core body temperature and in environmental temperature (Norris, 2019). Heat is transferred to the external environment through the physical processes of radiation, convection, evaporation, and conduction. These processes are defined and illustrated in Table 26-2. Other heat losses occur through evaporation of sweat, through warming and humidifying of inspired air, and through elimination of urine and feces.

Table 26-2 Mechanisms of Heat Transfer

	RADIATION	CONVECTION	EVAPORATION	CONDUCTION
Definition	The diffusion or dissemination of heat by electromagnetic waves	The dissemination of heat by motion between areas of unequal density	The conversion of a liquid to a vapor	The transfer of heat to another object during direct contact
Example	The body gives off waves of heat from uncovered surfaces.	An oscillating fan blows currents of cool air across the surface of a warm body.	Body fluid in the form of perspiration and insensible loss is vaporized from the skin.	The body transfers heat to an ice pack, causing the ice to melt.

Factors Affecting Body Temperature

A variety of factors affect body temperature. These factors include time of day (circadian rhythms), age, biologic sex, physical activity, state of health, and environmental temperatures.

Circadian Rhythms

Many environmental and physiologic processes occur in repeated cycles of time. Some events in humans recur at 24-hour intervals, referred to as circadian (meaning nearly every 24 hours) rhythms. Predictable fluctuations in

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

measurements of body temperature and blood pressure are examples of functions that have a circadian rhythm. For instance, body temperature can vary as much as 1.0°F (0.5°C) during the course of a day and is usually lower in the early morning than in the late afternoon and early evening (Jensen, 2019). This variation tends to be somewhat greater in infants and children. The peak elevation of a person's temperature occurs between 3 and 6 PM.

Age and Biologic Sex

Older adults lose some thermoregulatory control with aging; body temperatures in older adults may be lower than the average adult temperature (Touhy & Jett, 2018). Both the very old and the very young are more sensitive to changes in environmental temperature. Older adults are at risk for harm from extremes of temperature due to impaired thermoregulatory responses. The body temperature of infants and children changes more rapidly in response to both hot and cold air temperatures.

Consider **Noah Shoolin**, the 2-year-old brought to the emergency department by his mother. The nurse assessing the child's temperature would need to keep in mind the effect of environmental temperature changes on a child of this age. Efforts to prevent chilling and overheating would be incorporated into the child's care plan.

Women tend to experience more fluctuations in body temperature than do men, probably as the result of changes in hormones. The increase in progesterone secretion at ovulation increases body temperature as much as 0.5° to 1.0°F (0.3° to 0.5°C) (Jensen, 2019).

Physical Activity

Physical exertion increases body temperature. Increased metabolism resulting from muscle activity results in the production of heat. When evaluating temperature measurements, the nurse should consider whether the patient has participated in recent physical activity.

State of Health

Alterations in a person's health can contribute to variations in body temperature. The presence of certain disease conditions and other health problems may result in alterations in body temperature. Refer to the Increased Body Temperature and Decreased Body Temperature discussions on pages 720–721.

Environmental Temperature

Most of us respond to changes in environmental temperature by wearing clothing that either allows increased heat loss when it is hot or retains heat when it is cold. When one is exposed to extreme cold without adequate protective clothing, heat loss may be increased to the point of **hypothermia** (low body temperature). Similarly, if one is exposed to extremes of heat for long periods of time, **hyperthermia** (high body temperature) may result. Both hypothermia and hyperthermia may cause serious illness or death.

Normal Body Temperature

Body temperature varies among people, with a range of 0.3° to 0.6°C (0.5° to 1.0°F) from the average temperature considered to be within normal limits. However, wider variations from the average temperature may be normal for some people. A person with a normal body temperature is referred to as **afebrile** (without fever). Refer to Table 26-1 (on page 718) for the normal temperature ranges for various age groups.

Increased Body Temperature

Fever or **pyrexia** is an increase above normal in body temperature. A person with a fever is said to be **febrile**. Fever occurs in response to an upward displacement of the thermoregulatory set point in the hypothalamus, caused by pyrogens (substances that cause fever). Substances that can trigger this increase in temperature include bacteria, bacterial products, and whole microorganisms, such as viruses. Fever may also occur as a result of chemicals produced in the body in response to tissue injury, such as from myocardial infarction (MI), pulmonary emboli, cancer, trauma, and surgery. Although the purpose of fever is not fully understood, it signals increased immune function and inflammation, and is a valuable indicator of health status.

Most fevers, unless extremely high (above 40°C [104°F]), are not harmful (Norris, 2019). In fact, there are many beneficial effects of fever, including destruction of disease-causing microorganisms, increased susceptibility of disease-causing microorganisms to anti-infective agents, and enhanced response by the immune system (Norris). However, when fever is equal to or greater than 41°C (106°F), it is referred to as hyperpyrexia and is a medical emergency. The body must be cooled rapidly to prevent complications (Wasserman et al., 2021).

Box 26-2 Terms and Definitions for Types of Fever

Intermittent: The body temperature returns to normal at least once every 24 hours.
Remittent: The body temperature does not return to normal and fluctuates a few degrees up or down.
Sustained or Continuous: The body temperature remains above normal with minimal variations.
Relapsing or Recurrent: The body temperature returns to normal for one or more days with one or more episodes of fever, each as long as several days.

Source: Adapted from Norris, T. L. (2019). *Porth's essentials of pathophysiology* (5th ed.). Wolters Kluwer.

When the thermostatic set point of the hypothalamus is increased in response to a pyrogen, the hypothalamus initiates temperature-rising mechanisms: shivering, piloerection, vasoconstriction, and increased metabolism. After the body temperature rises to the new set point, heat-loss mechanisms (sweating, vasodilation, increased respirations) keep the body temperature from rising to dangerous levels. Most fevers are self-limiting, and the temperature returns to normal after the factors causing it are controlled. Box 26-2 lists terms used to describe types of fever.

The onset and significance of a fever from an illness differs according to age. The onset of a fever, which can be sudden or gradual, typically is more rapid in children than in adults. A mild elevation in temperature might indicate a serious infection in infants younger than 3 months of age who do not have well-developed temperature-control mechanisms. Older adults often have a lower baseline body temperature. Therefore, fever may be one of the later signs of illness with temperature elevations of only slightly above normal, even in a serious infection. It is important to assess baseline norm for body temperature when an older adult is well, in order to be able to identify unique manifestations of fever (Toughy & Jett, 2018).

Other types of increased body temperature are hyperthermia, neurogenic fever, and fever of unknown origin (FUO). Hyperthermia differs from fever in that the hypothalamic set point is not changed, but in situations of extreme heat exposure or excessive heat production (e.g., during strenuous exercise), the mechanisms that control body temperature are ineffective. Neurogenic fever is the result of damage to the hypothalamus from pathologies such as intracranial trauma, intracranial bleeding, or increased intracranial pressure. This type of fever does not respond to antipyretic medications (Norris, 2019). A fever of 38.3°C (101°F) or higher that lasts for 3 weeks or longer without an identified cause after a minimal diagnostic workup is identified as a FUO (Fusco et al., 2019; Mulders-Manders et al., 2015). Infections, such as tuberculosis or human immunodeficiency virus, malignancies, cirrhosis, and noninfectious inflammatory diseases are causes of FUO (Fusco et al., 2019; Norris, 2019).

Physical Effects of Fever

Patients with fever may experience loss of appetite; headache; hot, dry skin; flushed face; thirst; muscle aches; and fatigue. Respirations and pulse rate increase. Infants and children may experience febrile seizures as a result of a fever (Schellack, N., & Schellack, G., 2019). Older adults may experience periods of confusion and delirium related to an increased body temperature (Hinkle et al., 2022). Fever blisters may develop in some people as the fever activates the type I herpes simplex virus. Fluid, electrolyte, and acid–base imbalances are potentially dangerous complications of fever.

Treatment of Fever

Fever is an important part of a person's defense mechanisms against infection. Determining the cause of the fever and treating its underlying cause is an important part of patient care. Nursing care related to fever focuses on increasing patient comfort and preventing complications.

If the fever is the result of a bacterial or other type of microbial infection, the appropriate antibiotic or anti-infective may be prescribed. Antipyretic (fever-reducing) drugs, such as aspirin, ibuprofen, or acetaminophen, may be administered in certain circumstances, but routine antipyretic administration is usually avoided (Ludwig & McWhinnie, 2019). These drugs reset the elevated set point regulated by the hypothalamus. However, the National Reye's Syndrome Foundation, the U.S. Surgeon General, the U.S. Food and Drug Administration (FDA), the Centers for Disease Control and Prevention (CDC), the American Academy of Pediatrics (AAP), and the World Health Organization (WHO) recommend that aspirin and combination products containing aspirin not be taken by anyone younger than 19 years of age during fever-causing or flulike illnesses (American Academy of Pediatrics, 2021; National Reye's Syndrome Foundation, n.d.).

Modifications of the external environment may be implemented to increase heat transfer from the internal to the external environment, including the use of cool sponge baths, cool packs, and hypothermia (cooling) blankets.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Guidelines for Nursing Care 26-1 (on page 722) outlines the procedure for using a hypothermia blanket. Oral fluids are increased to maintain cellular and intravascular status and prevent dehydration. Simple carbohydrates are included in the diet to prevent tissue breakdown from the hypermetabolic state.

QSEN PATIENT-CENTERED CARE

The health practices and beliefs of patients and/or family members/caregivers related to fever and other symptoms may be influenced by cultural beliefs and practices. Culturally and ethnically sensitive strategies must be considered when providing interventions and patient education related to fever.

Decreased Body Temperature

Hypothermia is a core body temperature below 35°C (95°F). Hypothermia occurs when the compensatory physiologic responses meant to produce and retain heat are overwhelmed by unprotected exposure to cold environments. This may be a result of accidental exposure or impaired perception of cold, which occurs particularly in older adults or the disabled. Chronic conditions—such as alcoholism, malnutrition, and hypothyroidism—increase the risk of hypothermia. Patients in the perioperative period and newborn infants are also at increased risk. Death may occur when body temperature falls below 35°C (95°F), but survival has been reported in isolated cases (such as in drowning in very cold water or burial in snow) when body temperatures have fallen in the range of severe hypothermia (26°C [78.8°F]) (Kuhnke et al., 2019). Survival is possible because rates of chemical reactions in the body are slowed, thereby decreasing the metabolic demands for oxygen.

Therapeutic hypothermia, the purposeful lowering of the core body temperature, has been used to improve outcomes after brain injury, during certain surgeries and after cardiac arrest (Morton & Fontaine, 2018; Norris, 2019). This decreased body temperature reduces metabolic rate and oxygen demand of the body to improve survival and neurologic outcomes (Alne, 2020).

Physical Effects of Hypothermia

Patients with hypothermia may experience poor coordination, slurred speech, poor judgment, amnesia, hallucinations, and stupor. Respirations decrease and the pulse becomes weak and irregular with lowering blood pressure.

Treatment of Hypothermia

Treatment of hypothermia includes rewarming the patient. Rewarming can be accomplished by covering with additional clothing and blankets, the use of heating blankets and pads, and radiant warmers. Warm fluids are administered either orally or through the intravenous route. Additional treatments include support of vital functions and the prevention and treatment of complications (Norris, 2019).

Assessing Temperature

To accurately assess body temperature, the nurse must know what equipment to use, which site to choose, and what method is appropriate. Although the measurement of temperature may be delegated to assistive personnel (AP), the nurse is responsible for assessing the findings, assessing the effect(s) of changes in body temperature, and implementing appropriate interventions. The nurse is also responsible for teaching the patient and caregiver(s) about methods of temperature measurement, normal values, and the need to communicate abnormal findings.

Equipment

Body temperature, measured in degrees, may be assessed with a variety of devices—electronic and digital thermometers, tympanic membrane thermometers, disposable single-use thermometers, temporal artery thermometers, noncontact infrared skin thermometers, and automated monitoring devices. Figure 26-1 illustrates several different types of thermometers. Each type of device has factors to consider when deciding the choice of appropriate thermometer when measuring a patient's temperature. The patient's health status may also influence the choice of device and measurement site, such as in situations requiring absolute accuracy in temperature measurement, including neonates or critically ill patients (Brosinski et al., 2018; Backer Mogensen et al., 2018; Fitzwater et al., 2019; Franconi, et al., 2018; Gates et al., 2018; Kiekkas et al., 2019). Refer to the discussions related to each type of thermometer (on pp. 723–724). No matter which type of thermometer is used, it is very important to follow the manufacturer's instructions to ensure an accurate measurement. Body temperature is documented in either Celsius or Fahrenheit degrees. Table 26-3 provides equivalent Celsius and Fahrenheit values as well as a method for conversion.

Guidelines for Nursing Care 26-1

Using a Hypothermia Blanket to Regulate Body Temperature

A hypothermia blanket, or cooling pad, is a blanket-sized aquathermia pad that conducts a cooled solution, usually distilled water, through coils in a plastic blanket or pad. It operates much like an aquathermia pad (discussed in Chapter 33), except that the liquid is cooled instead of heated. Placing a patient on a hypothermia blanket or pad helps to lower body temperature. The nurse monitors the patient's body temperature and can reset the blanket setting accordingly. The blanket also can be preset to maintain a specific body temperature; the device continually monitors the patient's body temperature using a temperature probe (which is inserted rectally or in the esophagus or placed on the skin) and adjusts the temperature of the circulating liquid accordingly. When applying a hypothermia blanket, follow these steps:

-  Perform hand hygiene and put on PPE, if indicated.
- Review the prescribed intervention for the application of the hypothermia blanket. Obtain consent for the therapy per facility policy.
- Check that the water in the electronic unit is at the appropriate level. Check the temperature setting on the unit to ensure it is within the safe range.
- Apply lanolin or a mixture of lanolin and cold cream to the patient's skin where it will be in contact with the blanket.
- Turn on the blanket and make sure the cooling light is on. **Verify that the temperature limits are set within the desired safety range.**
- Place the hypothermia blanket on the bed and cover it with a sheet so that the patient's skin does not come in direct contact with the cold blanket. Position the blanket under the patient so that the top edge of the pad is aligned with the patient's neck.
- Put on gloves. Lubricate the rectal probe and insert it into the patient's rectum unless contraindicated. Or tuck the skin probe deep into the patient's axilla and tape it in place. For patients who are comatose or anesthetized, use an esophageal probe. Remove gloves and perform hand hygiene. Attach the probe to the control panel for the blanket.
- Wrap the patient's hands and feet in gauze if prescribed, or if the patient desires. For male patients, elevate the scrotum off the hypothermia blanket with towels.
- Recheck the thermometer and settings on the control panel.
- **Turn and position the patient regularly (every 30 minutes to 1 hour).** Keep linens free from condensation. Reapply cream, as needed. Observe the patient's skin for change in color, changes in lips and nail beds, edema, pain, and sensory impairment.
- **Monitor vital signs and perform a neurologic assessment, per facility policy, usually every 15 minutes, until the body temperature is stable.** In addition, monitor the patient's skin integrity, peripheral circulation, and fluid and electrolyte status, per facility policy.
- Observe for signs of shivering, including verbalized sensations, facial muscle twitching or twitching of extremities, or hyperventilation.
- Turn off the blanket according to facility policy, usually when the patient's body temperature reaches 1 degree above the desired temperature. **Continue to monitor the patient's temperature until it stabilizes.**
-  Remove PPE, if used. Perform hand hygiene.

Table 26-3 Equivalent Celsius and Fahrenheit Temperatures[a]

CELSIUS	FAHRENHEIT
35.0	95.0
36.0	96.8
36.5	97.6
37.0	98.6
37.5	99.5
38.0	100.4
38.5	101.3
39.0	102.2
40.0	104.0
41.0	105.8

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

[a]To convert Fahrenheit to Celsius, subtract 32 and multiply by 5/9. To convert Celsius to Fahrenheit, multiply by 9/5 and add 32.

Glass thermometers with mercury-filled bulbs are not used in health care institutions to measure body temperature due to federal safety recommendations (U.S. Environmental Protection Agency [EPA], n.d.). Some states and municipalities have laws or ordinances barring the sale and/or distribution of mercury fever thermometers (U.S. EPA). However, patients may still be using mercury thermometers at home. Nurses should encourage patients to use alternative devices, such as digital thermometers, to measure body temperature and include patient teaching as part of the plan of care. Bulb-type glass thermometers containing liquids other than mercury are available. This type of thermometer is prone to breakage and should never be used to take a temperature for a person who is unconscious or irrational, or for infants and young children.

FIGURE 26-1. Types of thermometers used to assess body temperature. **A.** Electronic thermometer. **B.** Tympanic membrane thermometer. **C.** Disposable thermometer for measuring oral temperature; the dots change color to indicate temperature. **D.** Temporal artery thermometer. **E.** Noncontact infrared thermometer. (*Source:* Part C. Medical Indicators, Inc. Part E. FDA.)

Technology Alert

Neonates are at risk for hypothermia due to an immature temperature regulation mechanism. Hypothermia is one of the most important risk factors for morbidity and mortality in newborn infants (World Health Organization, n.d., as cited in Tanigasalam et al., 2019). The use of a novel hypothermia monitoring and alert bracelet device (BEMPU Bracelet) has been suggested as a screening tool to detect and alert for neonatal hypothermia. Use of the BEMPU can aid in identification of hypothermia and facilitate prompt

management, preventing complications associated with hypothermia (Tanigasalme et al., 2019).

Equipment that is shared among patients is potentially contaminated and can contribute to the spread of disease-causing microorganisms (John et al., 2017). Nondisposable thermometers used to measure body temperature for more than one individual have been shown to be a possible source of transfer of microorganisms from equipment to room surfaces, other health care equipment, other health care providers, and patients (John et al., 2018). Effective strategies to reduce the risk for microbial transmission related to use of nondisposable thermometers are important considerations. Cleaning and disinfection of thermometers before and after use are critical interventions.

ELECTRONIC AND DIGITAL THERMOMETERS

Nondisposable electronic and disposable digital thermometers measure oral, rectal, or axillary body temperature over a period from a few seconds to 60 seconds, depending on the site and product used (Jensen, 2019). These battery-operated devices provide a numerical temperature display. The devices also have disposable probe covers to reduce the risk of transmission of microorganisms. Some models also provide memory recall of previous temperature measurements, a full 60-second pulse timer, and automatic conversion from the Fahrenheit to the Celsius scale. It is important to maintain calibration and charging of the device (Jensen, 2019).

TYMPANIC MEMBRANE THERMOMETERS

Tympanic membrane thermometers use infrared sensors to detect heat given off by the tympanic membrane, reflecting the temperature of the blood flowing in the carotid artery. The probe is covered with a probe cover and inserted into the ear canal tightly enough to seal the opening. The reading takes from 1 to 3 seconds, depending on the product. Studies conflict regarding the accuracy of this method, particularly in patients with temperature elevations (Backer Mogensen et al., 2018; Gates et al., 2018; Kurnat-Thoma et al., 2018; Ryan-Wenger et al., 2018). As such, it is important to use proper technique, maintain calibration, and adhere to manufacturer's guidelines for use and consider the method of assessment.

Remember **Noah Shoolin**, the toddler described at the beginning of the chapter? Although a tympanic thermometer yields a quick reading, the nurse would need to verify the accuracy of the reading, especially in light of the child's current upset state, possibly by asking the mother if she had taken the child's temperature before coming to the emergency department or by using an alternative method.

TEMPORAL ARTERY THERMOMETERS

Temporal artery thermometers measure body temperature by capturing the heat emitted by the skin over the temporal artery. These devices are battery operated and have a temperature display. Kurnat-Thoma et al. (2018) and Opersteny et al. (2017) found temporal artery measurements are an accurate method for noninvasive temperature assessment. However, operator technique and cleanliness of the thermometer lens can influence the reading (Furlong et al., 2015). Additional studies conflict regarding the accuracy of this method, particularly in patients with temperature elevations (Backer Mogensen et al., 2018; Brosinski et al., 2018; Fitzwater et al., 2019; Gates et al., 2018; Ryan-Wenger et al., 2018). As such, it is important to use proper technique and adhere to manufacturer's guidelines for use, and to consider the method of assessment (Brosinski et al., 2018; Fitzwater et al., 2019; Kiekkas et al., 2019).

DISPOSABLE SINGLE-USE THERMOMETERS

Disposable single-use thermometers are nonbreakable and register the temperature within seconds. Because they are used only once, they eliminate the danger of cross-infection and are sometimes used for patients requiring transmission-based precautions.

Temperature-sensitive patches or tape, commonly applied to the abdomen or forehead, change color at different temperature ranges. These devices may be used to screen the temperature of a toddler or young child at home. This method of temperature measurement is inaccurate (Robertson & Hill, 2019). A thermometer should be used to reassess the temperature if the color on the tape or patch indicates that the temperature is out of the normal average range.

NONCONTACT INFRARED THERMOMETERS

Noncontact infrared (IFR) thermometers measure body temperature by capturing the heat emitted by the skin over body surfaces at various locations (Berksoy et al., 2018; Wang et al., 2013). These devices are battery operated and have a

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

temperature display, and offer a safe, simple, comfortable, and rapid measurement of body temperature (Berksoy et al., 2018). Use of a noncontact IFR thermometer does not require any body surface contact, no disposable probe covers are needed, and the risk of cross-infection is negligible (U.S. Food and Drug Administration [FDA], 2020a; Wang et al., 2013). However, comparisons of noncontact IFR thermometer measurements with tympanic, temporal artery and axillary body temperature measurement have resulted in inconsistent findings (Berksoy et al., 2018; Franconi et al., 2018). This method of temperature measurement has been suggested for use as screening for fever, not for ongoing monitoring of body temperature (Bayhan et al., 2014; Berksoy et al., 2018; Canadian Agency for Drugs and Technologies in Health, 2014). These devices must be used properly to get accurate readings and are not effective if used as the only means of detecting infection, such as screening to detect COVID-19 infections (U.S. FDA, 2020b). It is important to consider facility policy and procedures related to use; consider the method of assessment; and adhere to manufacturer's guidelines for use.

AUTOMATED MONITORING DEVICES

Automated monitoring devices are used in various health care settings to measure body temperature, pulse, respirations, and blood pressure simultaneously. These devices require less of the nurse's time, especially when these assessments need to be conducted frequently. Temperature sensors may be part of certain invasive devices used in critical care settings, such as pulmonary artery catheters, special rectal probes, and bladder catheters, allowing for continuous measurement of body temperature (Morton & Fontaine, 2018).

Technology Alert

Frequent monitoring of body temperature is an important aid in early detection of changes in the condition of critically ill patients (Schell-Chaple et al., 2018). Standard thermometry methods used in intensive care settings are invasive, may have barriers to use, may be contraindicated, or may not be available (Schell-Chaple et al.). The SpotOn system (3M Healthcare) uses a control unit, cable, and small disposable sensor applied to the lateral part of the patient's forehead to provide a continuous, noninvasive estimate core temperature and is an alternative to invasive temperature monitoring methods.

Sites and Methods of Assessing Body Temperature

The nurse is expected to choose an alternate, appropriate site, and the correct equipment for temperature measurement based on the patient's condition, facility policy, and prescribed interventions. Factors affecting site selection include the patient's age, state of consciousness, amount of pain, and other care or treatments (such as oxygen administration) being provided. Health facility policies and procedures may also provide guidance related to the site to be used for assessing patients' temperatures. If a temperature reading is obtained from a site other than the oral route, it is important to document the site of the measurement along with the result to ensure accurate comparison of data. If no site is listed with the documentation, it is generally assumed to be the oral route.

The sites most commonly used to assess body temperature are oral (sublingual), tympanic, temporal artery, rectal, and axillary. The probe is placed under the tongue (sublingual area) of a person's mouth to assess an oral temperature, in the anal canal to assess a rectal temperature, or in an axilla (armpit) to assess an axillary temperature. A probe is placed in the ear to assess a tympanic temperature. Temporal artery thermometers are swiped over the skin covering the temporal artery. For many clinical purposes, it is satisfactory to assess an oral, tympanic, temporal artery, axillary, or rectal temperature, provided proper technique is used, the site of the temperature is documented, and normal variations among the methods are considered. Comparing the recordings using two different sites is a method for double-checking the validity of an unusual measurement. The procedures for assessing body temperature at the oral, tympanic, temporal artery, axillary, and rectal sites, with rationale for each step, are outlined in Skill 26-1 (on pp. 747–754). The procedure for measuring temperature using a noncontact infrared thermometer is outlined in the Skill Variation included in Skill 26-1.

ASSESSING AN ORAL TEMPERATURE

When selecting the oral site, the patient must be able to close their mouth around the probe. Therefore, this site is not suitable for use with children younger than 6 years old, for some children with developmental delay, with patients who are unable to follow directions, with patients with changes in or inflammation of the oral mucosa, or for confused and comatose patients (Jensen, 2019; Mason et al., 2017; Opersteny et al., 2017). If a patient has had either hot or cold food or fluids or has been smoking or chewing gum, the general recommendation is to wait 15 to 30 minutes to allow the oral tissues to return to normal temperature. Mouth breathing can influence the results (Jensen, 2019). Oral temperatures should not be taken in people with diseases of the oral cavity, in those who have had surgery of the nose or mouth, or when there is a risk of seizures (Sund-Levander & Grodzinsky, 2013). In addition, oral temperatures should not be assessed in patients receiving oxygen by mask, because the time it takes to assess a reading is likely to result in a serious drop in the patient's blood oxygen level. Normal oral temperature readings range from 96.6° to 99.5°F (35.9° to 37.5°C) (Jensen, 2019; Weber & Kelley, 2018). The probe must remain in the sublingual pocket for the full period of measurement. Refer to Skill 26-1 (on pp. 747–754).

ASSESSING A TYMPANIC MEMBRANE TEMPERATURE

Infrared sensors in the thermometer sense heat from the body given off by the tympanic membrane. The thermometer does not touch the tympanic membrane. This site allows easy and safe measurement of temperature and is readily accessible. However, it should not be used for patients who have drainage from the ear, ear pain, ear infection, or scars on the tympanic membrane (Jensen, 2019). Temperature readings may be impacted by the presence of cerumen (earwax) (Oguz et al., 2018; Robertson & Hill, 2019). Normal tympanic temperature readings range from 98.2° to 100.9°F (36.8° to 38.3°C) (Jensen, 2019; Weber & Kelley, 2018). Refer to Skill 26-1 (on pp. 747–754).

Concept Mastery Alert

If a patient has drainage from the ear, ear pain, ear infection, or scarring on the tympanic membrane on one side, then the opposite ear may be used to measure the tympanic temperature.

ASSESSING A TEMPORAL ARTERY TEMPERATURE

Measurement on the right or left side of the forehead is equally effective. When taking a temporal artery temperature, assess for head coverings. Anything covering the area—such as a hat, hair, wigs, or bandages—would insulate the area, resulting in falsely high readings. If a patient is lying on the side, measure only the side of the head exposed to the environment. Do not measure temporal artery temperature over scar tissue, open lesions, or abrasions. Diaphoresis or sweat can impair the reading (Jensen, 2019). Move the thermometer across the forehead slowly and remain in contact with the skin to ensure accurate results. Temporal artery temperature readings are more accurate than axillary temperature measurement (Opersteny et al., 2017). Normal temporal artery temperature readings range from 98.7° to 100.5°F (36.3° to 38.1°C) (Jensen; Weber & Kelley, 2018). Refer to Skill 26-1 (on pp. 747–754).

ASSESSING AN AXILLARY TEMPERATURE

The axillary site may be used when both oral and rectal sites are contraindicated or when these sites are inaccessible but may provide readings that are less accurate than these sites (Jensen, 2019). As a result, axillary measurement should not be used where accurate temperature measurement is required. The axilla remains the most common place for temperature measurement in the neonate (Oguz et al., 2018). Axillary readings are affected by local blood flow, placement of the probe and closure of the axillary cavity, and the measurement time must be sufficient (Oguz et al., 2018; Sund-Levander & Grodzinsky, 2013). Place the probe in the center of the axilla; hold the patient's arm by the patient's side until the measurement is complete. Normal axillary temperature readings range from 95.6° to 98.5°F (35.4° to 36.9°C) (Jensen, 2019; Weber & Kelley, 2018). Refer to Skill 26-1 (on pp. 747–754).

ASSESSING A RECTAL TEMPERATURE

The rectal temperature is considered to be reflective of core body temperature and one of the most accurate routes (Jensen, 2019). The rectal route may be used when other routes are not practical or when an accurate measurement is required (Jensen, 2019). However, many patients are embarrassed at having their temperature taken rectally. The rectal site should not be used in newborns, children with diarrhea, and in patients who have undergone recent rectal, anal, vaginal, or prostate surgeries or have a disease of the rectum (Weber & Kelley, 2018). Because the insertion of the thermometer into the rectum can slow the heart rate by stimulating the vagus nerve, assessing a rectal temperature for patients with heart disease or after cardiac surgery may not be allowed in some institutions. In addition, assessing a rectal temperature is contraindicated in patients who are neutropenic (have low white blood cell counts, such as in leukemia) and in patients who have certain neurologic disorders (e.g., spinal cord injuries). Do not insert a rectal thermometer into a patient who has a low platelet count (thrombocytopenia). The rectum is very vascular, and a thermometer could cause rectal bleeding. Normal rectal temperature readings range from 97.4° to 100.5°F (36.3° to 38.1°C) (Jensen, 2019; Weber & Kelley, 2018). Refer to Skill 26-1 (on pp. 747–754).

ASSESSING TEMPERATURE WITH A NONCONTACT INFRARED THERMOMETER

Noncontact infrared (IFR) thermometers measure body temperature by capturing the heat emitted by the skin over body surfaces. This method of temperature measurement has been suggested for use as screening for fever, not for ongoing monitoring of body temperature (Bayhan et al., 2014; Berksoy et al., 2018; Canadian Agency for Drugs and Technologies in Health, 2014). Locations recommended for use for measurement include over the forehead (temporal artery), the neck (carotid artery), umbilicus, axilla, and nape of the neck (Berksoy et al., 2018; U.S. FDA, 2020a; Wang et al., 2013). Accuracy of measurement may be affected by the technique used during measurement, including positioning of the thermometer, as well as the presence of head covers and the environment (U.S. FDA, 2020a). Temperature measurement should be performed in a draft-free space, out of direct sun, and away from radiant heat sources (U.S. FDA, 2020a). The noncontact IFR thermometer should be placed in the testing environment or room for 10 to 30 minutes prior to use to allow the device to adjust to the environment (U.S. FDA, 2020a). Refer to the Skill Variation included in Skill 26-1 on page 747.

PULSE

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

The peripheral **pulse** is a throbbing sensation that can be palpated (felt) over a peripheral artery, such as the radial artery or the carotid artery. Peripheral pulses result from a wave of blood being pumped into the arterial circulation by the contraction of the left ventricle. As the heart contracts to eject blood into an already full aorta, smooth muscle in the arteries expands to compensate for the increase in pressure of the blood. This rhythmic distention of the arterial walls is the result of surges of blood as the heart beats. The distention of the arteries moves along the arterial system until it reaches the capillaries, where vessel walls lack elasticity and peripheral resistance to blood flow. The strength of the pulse reflects the amount of blood ejected with each beat of the heart (Jensen, 2019). The peripheral pulses may be felt wherever an artery passes over a solid structure, such as a bone or cartilage.

Characteristics of the peripheral pulse include rate, rhythm, strength (amplitude), and elasticity. These characteristics are indicators of the effectiveness of the heart as a pump, the volume of blood ejected with each heartbeat (stroke volume), and the adequacy of peripheral blood flow. The heart rate affects the amount of blood ejected by the heart with each beat and is determined by the frequency with which the ventricle contracts. The strength and rhythm affect how much blood is ejected and whether the beat is regular in rhythm. Further information about the control and mechanisms involved with blood flow and stroke volume is provided later in this chapter with the discussion of blood pressure and in Chapter 40.

An apical pulse may also be auscultated (listened to) over the apex of the heart as the heart beats. Heart sounds, which are produced by closure of the valves of the heart, are characterized as "lub-dub." The apical pulse is the result of closure of the mitral and tricuspid valves ("lub") and aortic and pulmonic valves ("dub"). The combination of the two sounds is counted as one beat.

Further information related to the characteristics of pulses is discussed later in this chapter.

Physiology of the Pulse

The pulse is regulated by the autonomic nervous system through the sinoatrial (SA) node (the pacemaker) of the heart. Parasympathetic stimulation of the SA node via the vagus nerve decreases the heart rate, and sympathetic stimulation of the SA node increases the heart rate and force of contraction. Additional information about the conduction system and function of the heart is discussed in Chapter 40. The pulse rate is the number of pulsations felt over a peripheral artery or heard over the apex of the heart in 1 minute. This rate normally corresponds to the same rate at which the heart is beating.

Table 26-4 Factors Affecting Pulse Rate

Age	Older adults may have a decreased pulse rate. Aging affects metabolic rate and can decrease the pulse rate.
Biologic sex	Women on average have slightly higher pulse rates than men.
Physical activity	Pulse rate increases with exercise to meet increased metabolic demands and ensure adequate oxygenation of tissues. Well-conditioned athletes may have a significantly decreased pulse rate. Regular cardiovascular exercise contributes to greater efficiency and strength of the heart muscle
Body Temperature	Elevated body temperature (fever/pyrexia) causes increased pulse rate due to increased metabolic demands and compensatory mechanisms to increase heat loss. With lowered body temperature (hypothermia), metabolism slows down with a corresponding decrease in pulse rate.
Stress	Increased levels of stress cause an increased pulse rate. Common sources of stress associated with increased pulse rate include pain, fear, and anxiety.
Medications	Many medications can cause alterations in pulse rate. Some medications increase a patient's pulse rate and others decrease a patient's pulse rate. Changes in pulse related to medication use can be an intended effect or an unintended adverse effect.
Presence of Disease and/or Health Conditions	Many acute and chronic health conditions affect a patient's pulse rate. Some diseases, such as chronic obstructive pulmonary disease and pneumonia, impair oxygenation and alter the pulse rate. Other health problems, such as sepsis, alter the pulse rate as a result of the body's response to infection. Peripheral vascular disease and heart failure affect the circulatory system and, as a result, affect the pulse.

Factors Affecting the Pulse

Many factors can affect both the heart rate and volume; however, compensatory mechanisms attempt to maintain a sufficient supply of blood to the cells at all times. For example, when the stroke volume decreases, such as when the blood volume is decreased because of hemorrhage, the heart rate increases to try to maintain the same cardiac output. Conversely, in a physically fit athlete whose heart pumps a maximum volume of blood per stroke, the heart rate may be at the low range or below the range of normal, yet the body cells remain adequately supplied. When assessing a patient's pulse, consider factors that could influence the pulse rate, including age, biologic sex, physical activity, fever, stress, medication use, and the presence of disease and/or health conditions. Table 26-4 identifies details related to each of these factors.

Normal Pulse Rate

The normal pulse rate for adolescents and adults ranges from 60 to 100 beats per minute (beats/min). The pulse rate increases and decreases in response to a variety of physiologic mechanisms. Pulse rate might also be altered by any of the factors discussed previously (Table 26-4). Normal pulse rates change across the life span, gradually diminishing from birth to adulthood (see Table 26-1 on page 718).

Increased Pulse Rate

As the heart rate increases, cardiac output usually also increases. However, **tachycardia**, a rapid heart rate, decreases cardiac filling time, which, in turn, decreases stroke volume and cardiac output, potentially leading to decreased tissue perfusion. An adult has tachycardia when the pulse rate is greater than 100 beats/min. Tachycardia is a normal response to exercise and emotion (Burns & Delgado, 2019). Tachycardia that persists at rest usually indicates some underlying problem (Burns & Delgado). Box 26-3 (on page 728) lists factors that may contribute to tachycardia.

Decreased Pulse Rate

Bradycardia is a pulse rate below 60 beats/min in an adult. A decrease in heart rate decreases cardiac output, potentially leading to a decrease in tissue perfusion. Bradycardia can be a normal finding in athletes and during sleep (Burns & Delgado, 2019). Bradycardia may not require treatment unless the patient is symptomatic (Burns & Delgado). Box 26-3 (on page 728) identifies factors that may contribute to bradycardia.

Pulse Strength (Amplitude)

The pulse strength (amplitude) refers to and describes the quality of the pulse in terms of its fullness; indicates the volume of blood flowing through the vessel; and reflects the strength of left ventricular contraction. Pulse strength is assessed by the feel of the blood flow through the vessel. The strength of each pulse beat is normally strong at all areas where an artery can be palpated (felt). There are several systems for grading the strength (amplitude) of arterial pulses. Nurses should be familiar with the system in use at their facility or institution. Table 26-5 (on page 728) presents one scale that is used to describe and document pulse strength (amplitude). In addition, the peripheral pulse may be described and documented as full and bounding when it is forceful or weak and thready when it is decreased in quality. Bounding pulses may occur with early stages of septic shock, exercise, fever, fluid volume excess, and anxiety (Jensen, 2019; Norris, 2019). Heart failure, hypovolemia, shock, hypernatremia (elevated plasma sodium level), and arrhythmias can cause decreased pulse strength (Jensen, 2019; Norris, 2019).

Box 26-3 Factors Contributing to Tachycardia and Bradycardia

Tachycardia	Bradycardia
• A decrease in blood pressure, such as occurs with blood loss, shock, trauma	• Coronary artery disease; myocardial infarction (MI; heart attack)
• An elevated body temperature	• Decreased body temperature
• Any condition resulting in poor oxygenation of blood, for example, chronic pulmonary disease or anemia	• Hypoxemia, obstructive sleep apnea
• Exercise	• Acute altered mental status, such as delirium
• Hyperthyroidism	• Hypothyroidism
• Pain	• Increased intracranial pressure and other central nervous system conditions, such as cerebral vascular accident ([CVA]; stroke)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Strong emotions, such as fear, anger, anxiety, and surprise
- Some medications (e.g., atropine, epinephrine)
- Response to vagal stimulation, such as ocular pressure or vomiting
- Some medications (e.g., digitalis, antiarrhythmics)

Pulse Rhythm

Pulse rhythm is the pattern of the beats and the intervals between them. Pulse rhythm is normally regular; the pulsations and the pauses between occur at evenly spaced intervals. An irregular pulse rhythm occurs when the beats and pauses between beats occur at unequal, varied intervals. An irregular pattern of heartbeats is called a **dysrhythmia**. Minor variations in regularity of the pulse may occur with respirations, with the rate increasing during inhalation and slowing during exhalation. This irregularity in rhythm occurs most commonly in children and young adults (Hinckle & Cheever, 2018; Jensen, 2019).

Pulse Elasticity

The normal artery feels smooth, straight, and resilient (springy); this finding is referred to as the elasticity of the artery or blood vessel (Jensen, 2019; Weber & Kelley, 2018). Arterial blood vessels become less elastic with increased age, resulting in a more rigid, less-resilient, and crooked arterial blood vessel (Eliopoulos, 2018; Jensen, 2019; Weber & Kelley, 2018).

Table 26-5 Pulse Strength (Amplitude)

GRADE	DESCRIPTION
0	Absent, unable to palpate
+1	Diminished, weaker than expected
+2	Normal; brisk, expected
+3	Bounding

M., Kinlay, S., Lookstein, R., Misra, S., Mureebe, L., Olin, J. W., Patel, R. A. G., Regensteiner, J. G., Schanzer, A., Shishehbor, M. H., Stewart, K. J., … Wijeysundera, D. N. (2017). 2016 AHA/ACC Guideline on the management of patients with lower extremity peripheral artery disease: Executive Summary. *Vascular Medicine*, *22*(3), NPI–NP43. https://doi.org/10.1177/1358863X17701592.

Assessing the Pulse

The pulse may be assessed by palpating peripheral arteries, by auscultating the apical pulse with a stethoscope, or by using a portable Doppler ultrasound. It is important to know how to use a stethoscope and which site and method are appropriate for an individual patient at any particular moment.

Remember **Tomas Esposito**, the middle-aged man requiring transmission-based infection-control measures and assessment? Although the nurse had difficulty auscultating his heart and lung sounds, the nurse would need to assess both his radial and apical pulse. It is possible that by palpating his radial pulse and then attempting to auscultate his apical pulse and not hearing anything, the nurse might have a clue leading her to suspect that the stethoscope was not functioning properly.

Equipment

Nurses most often use their fingers to assess the pulse by palpation, feeling the artery. However, various types of equipment may be used to assess a pulse. For example, the stethoscope is typically used to auscultate (listen to) the apical pulse. Doppler ultrasound may be used to assess pulses that are difficult to palpate. Electrocardiography is a graphic or digital recording of the electrical activity of the heart and may be used to assess the pulse rate and rhythm. Cardiac monitoring provides continuous observation of the patient's heart rate and rhythm. Additional basic information related to electrocardiography is discussed in Chapter 40 (p. 1599). Details of assessment with electrocardiography and cardiac monitoring are beyond the scope of this discussion. Refer to a medical-surgical or health assessment textbook for additional information regarding these interventions.

STETHOSCOPE

The stethoscope conducts sound from the patient's body to the listener and is used to auscultate (listen to) sounds not audible to the unaided ear (Jensen 2019; Weber & Kelley, 2018). Environmental noise is also blocked to help more clearly discern the sounds (Jensen). The acoustical stethoscope, the most common type used, has an amplifying mechanism connected to earpieces by tubing. The stethoscope has a chest piece, which includes the *diaphragm* and *bell*, flexible tubing, earpieces, and ear tips. The diaphragm is a large, flat disk, and the bell has a hollowed, upright, curved appearance (Fig. 26-2). The diaphragm is more useful for hearing high-frequency sounds, such as respiratory sounds, because it screens out low-frequency sounds. The bell screens out high-frequency sounds and is more useful for hearing low-frequency sounds, such as those commonly made by the heart and the blood within the vessels.

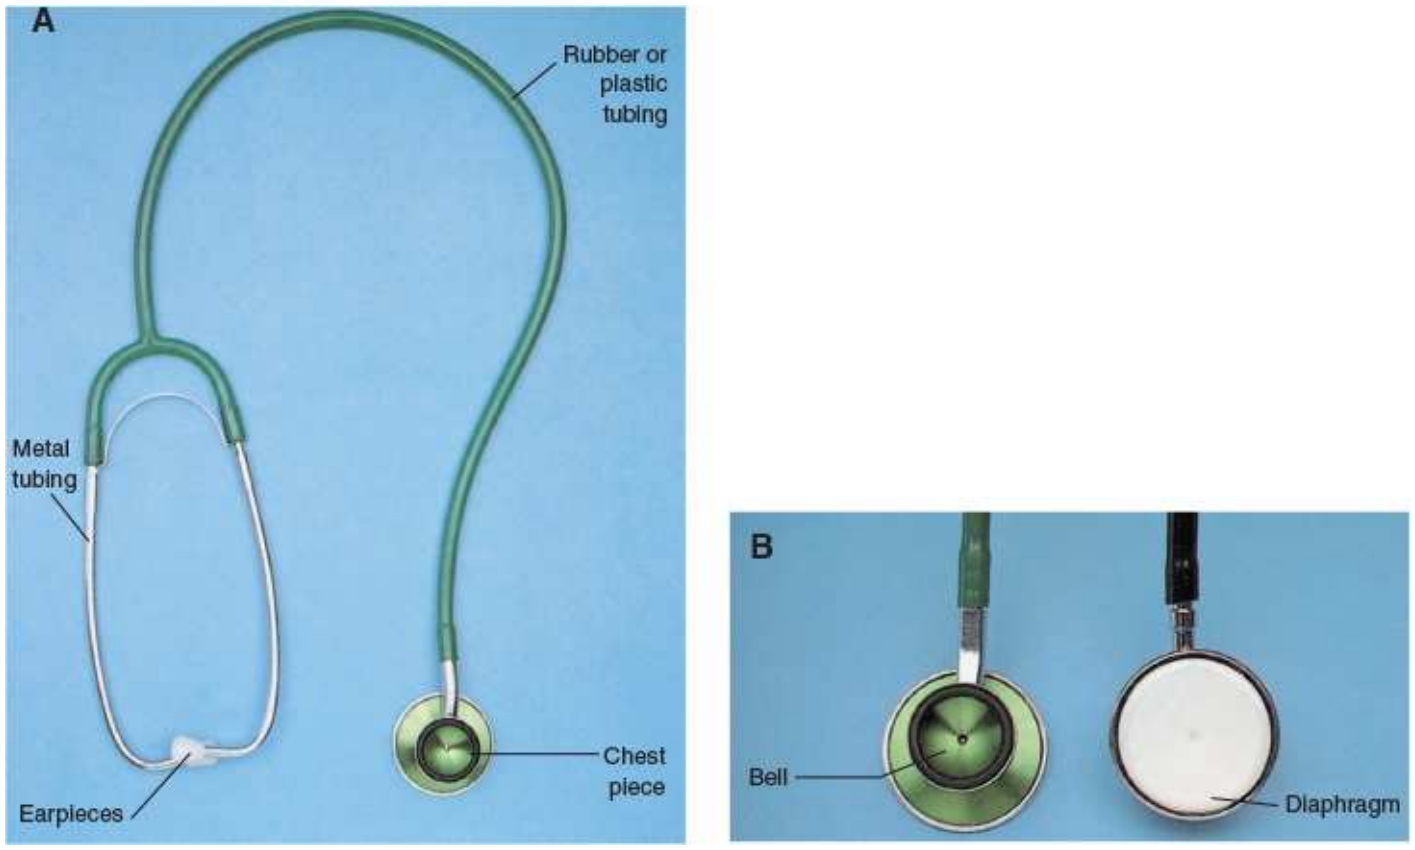

FIGURE 26-2. A stethoscope. **A.** Parts of a stethoscope. **B.** Parts of the chest piece; the bell and diaphragm. (*Source:* Used with permission from Weber, J. R., & Kelley, J. H. [2018]. Health assessment in nursing [6th ed.]. Wolters Kluwer, p. 43.)

The earpieces of the stethoscope should be selected to fit one's ear canals comfortably and snugly for the most effective auscultation. The ear pieces should be directed into the ear canal, toward the tympanic membrane, not against the ear itself. The ear tips should be large enough to fit snugly, but comfortably, to block out extraneous noises in the environment when the stethoscope is being used.

DOPPLER ULTRASOUND

A Doppler ultrasound device may be used to assess pulses that are difficult to palpate or auscultate. The device has an audio unit with an ultrasound transducer. Techniques for assessing pulses with a Doppler ultrasound device are outlined in Guidelines for Nursing Care 26-2 on page 730.

Sites and Methods of Assessing the Pulse

Nurses must know the correct site and method for assessing the pulse for individual patients. Although peripheral pulses are most frequently assessed as part of measurement of vital signs, an apical pulse or an apical–radial pulse should be assessed in certain situations, as described later.

ASSESSING PERIPHERAL ARTERIAL PULSES

Many peripheral artery sites might be used to assess the pulse by palpation. Figure 26-3 (on page 730) illustrates the most commonly used sites. Of these sites, the radial pulse site is assessed most often in children and adults. However, the radial pulse is difficult to palpate accurately in children younger than 2 years of age; the apical pulse should be auscultated for 1 minute for these patients (Jarvis & Eckhardt, 2020; Kyle & Carmen, 2021). Skill 26-2 (on pp. 755–757) describes the steps for assessing a peripheral pulse via palpation.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Circulation to the legs and feet may be assessed at the femoral, popliteal, posterior tibial, or dorsalis pedis sites. The carotid pulse site is used during emergency assessments, such as for patients who are in shock or have had a cardiac arrest. When taking a carotid pulse, lightly palpate only one side at a time to prevent any decrease in cerebrovascular circulation. The brachial pulse site is used most often for infants in these emergency situations.

ASSESSING THE APICAL PULSE

The apical pulse is obtained by listening with a stethoscope at the fifth intercostal space, left midclavicular line on the chest, and provides for assessment of a pulse rate and rhythm. In adults, the apical pulse is counted for 1 full minute. (Refer to the Guidelines for Nursing Care 26-3 on page 731.) Alternately, Jensen (2019) suggests it may be easier to assess the apical pulse on some patients at the second or third intercostal space, left sternal border (Erb's point). At this position on the chest, the heart is closer to the chest wall, so heart sounds may more easily be heard, and avoids exposing the breast in women (Jensen, 2019). The apical rate of an infant can also be easily palpated with the fingertips in addition to auscultation.

An apical pulse rate and rhythm should be assessed when a peripheral pulse is difficult to assess accurately because it is irregular, weak, or very rapid. An apical pulse is also assessed when giving medications that alter heart rate and rhythm. Apical pulse measurement is the preferred method of pulse assessment for children less than 2 years of age (Jarvis & Eckhardt, 2020; Kyle & Carmen, 2021).

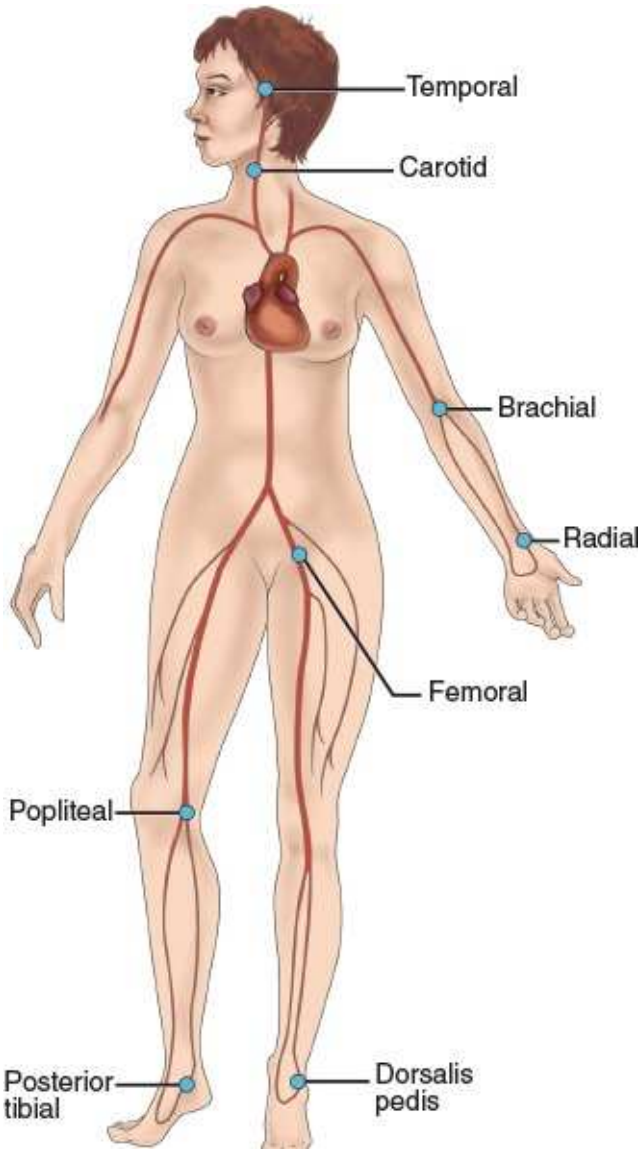

FIGURE 26-3. These arteries are located near the surface of the body. The pulse can be detected in any of these sites by light palpation.

Guidelines for Nursing Care 26-2

Assessing Peripheral Pulse Using a Portable Doppler Ultrasound Device

- Determine the need to use a Doppler ultrasound device for pulse assessment.
-  Perform hand hygiene and put on PPE, if indicated.
- Select the appropriate peripheral site based on assessment data.
- Move the patient's clothing to expose only the site chosen.
- Remove the Doppler from the charger and turn it on. Make sure that the volume is set at low.
- Place a small amount of conducting gel on the Doppler transducer probe. Turn the Doppler on.
- Hold the Doppler base in your nondominant hand. With your dominant hand, touch the probe lightly to the skin with the probe tip in the gel. Adjust the volume, as needed. Hold the probe perpendicular to the skin. Slowly move the Doppler tip around until the pulse is heard (see figure).

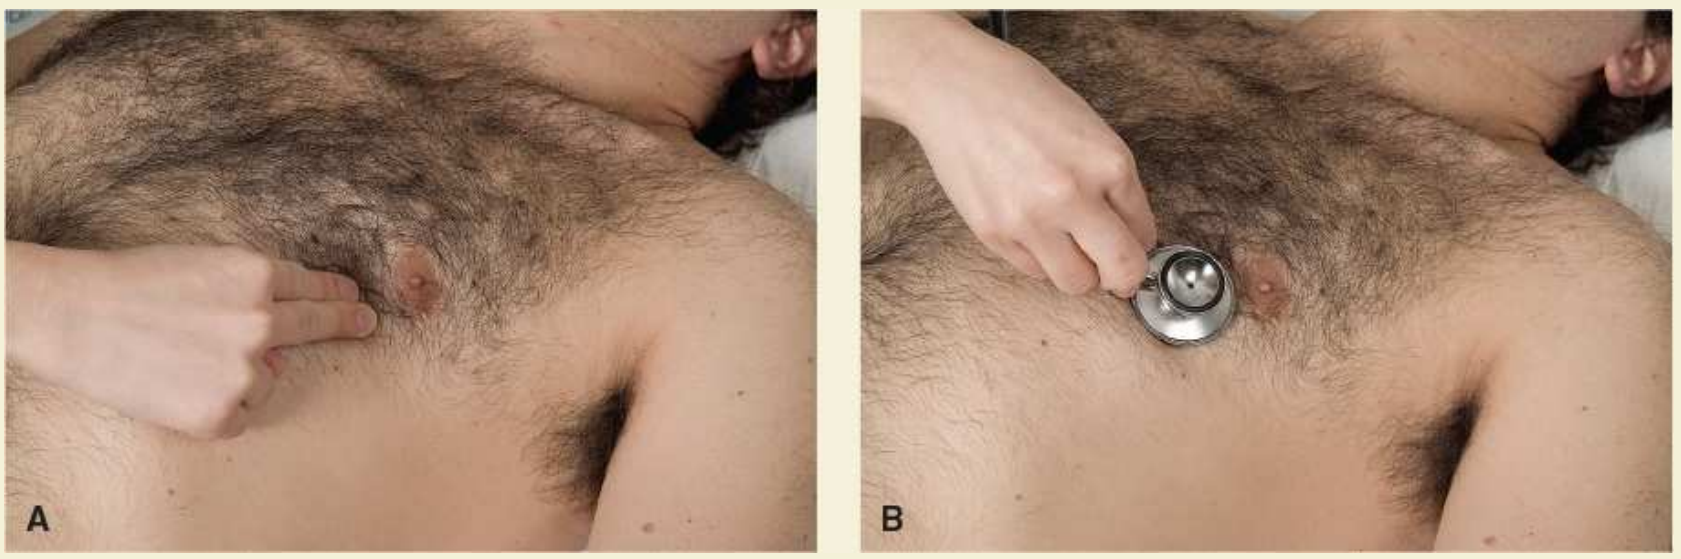
- **Using a watch with a second hand, count the heartbeat for 1 minute. Note the rhythm of the pulse.**
- Remove the Doppler tip and turn the Doppler off. Wipe excess gel off the patient's skin with a tissue.
- Place a small × over the spot where the pulse is located with an indelible pen, depending on facility policy. Marking the site allows for easier future assessment. It can also make palpating the pulse easier since the exact location of the pulse is known.
- Cover the patient and help the patient to a position of comfort.
- Wipe off any gel remaining on the Doppler probe with a tissue. Clean the Doppler probe per facility policy or manufacturer's recommendations.
- Return the Doppler to the charge base.
- Record pulse rate, rhythm, and site, and the fact that it was obtained with a Doppler ultrasound device.
-  Remove PPE, if used. Perform hand hygiene.

ASSESSING THE APICAL–RADIAL PULSE

Counting of the pulse at the apex of the heart and at the radial artery simultaneously is used to assess the apical–radial pulse rate. Comparison of these two pulse rates provides an indirect evaluation of the ability of each heart contraction to eject enough blood into the peripheral circulation to create a pulse (Jensen, 2019). A difference between the apical and radial pulse rates is called the **pulse deficit** and indicates that all of the heartbeats are not reaching the peripheral arteries or are too weak to be palpated. This deficit suggests in insufficient cardiac force or volume, leading to decreased tissue perfusion. Guidelines for Nursing Care 26-4 outlines the technique for taking an apical–radial pulse.

RESPIRATIONS

Respiration involves ventilation, diffusion, and perfusion. Ventilation (or breathing) is movement of gases in and out of the lungs; inspiration (or inhalation) is the act of breathing in, and expiration (or exhalation) is the act of breathing out. Unlike heart rate, which is controlled by the autonomic nervous system, ventilation (breathing) has both autonomic and voluntary control. Diffusion is the exchange of oxygen and carbon dioxide between the alveoli of the lungs and the circulating blood. Perfusion is the exchange of oxygen and carbon dioxide between the circulating blood and tissue cells.



Guidelines for Nursing Care 26-3

Assessing the Apical Pulse

-  Perform hand hygiene and put on PPE, if indicated.
- Use an alcohol swab to clean the diaphragm of the stethoscope. Use another swab to clean the earpieces, if necessary.
- Assist the patient to a sitting or reclining position and expose the chest area; move the patient's clothing to expose only the apical site.
- Hold the stethoscope diaphragm against the palm of your hand for a few seconds (to warm it).
- **Palpate the space between the fifth and sixth ribs (fifth intercostal space), and move to the left midclavicular line.** Place the diaphragm over the apex of the heart (see figure). Alternatively, auscultate an apical pulse in the second or third intercostal space left sternal border (Erb point) (Jensen, 2019).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Listen for heart sounds ("lub-dub"). Each "lub-dub" counts as one beat.
- Using a watch with a second hand, count the heartbeat for 1 minute.
- Note the rhythm of the beats.
- Clean the diaphragm of the stethoscope with an alcohol swab.
-  Remove PPE, if used. Perform hand hygiene.

The apical pulse is usually found at (**A**) the fifth intercostal space just inside the midclavicular line and can be heard (**B**) over the apex of the heart.

Although nurses assess the manifestations of changes in all of these respiratory events, the component that is measured as a vital sign is ventilation, more commonly called **respirations**. Respiratory system assessment is described further in Chapter 27. Measuring respirations allows for baseline assessment of respiratory function, as well as providing insight into the status of the patient's homeostatic control (the body's internal environment) and presence of physiologic conditions, such as hypoxia (Rolfe, 2019). Respiratory rate abnormalities are important predictors of deteriorating patient conditions and serious events, including cardiac arrest and intensive care admission (Malycha et al., 2019; Souza et al., 2019). Respiratory rate measurement is one of the few vital signs that is not easily measured by a monitor (Elliott & Baird, 2019). Accurate assessment and interpretation of respirations as part of vital sign measurement are important parts of clinical assessment (Rolfe, 2019).

Guidelines for Nursing Care 26-4

Taking an Apical–Radial Pulse

The following techniques are recommended to assess an apical–radial pulse rate:

- Two nurses are needed; one listens with a stethoscope over the apex of the heart for the heartbeat, and the other counts the rate at the radial artery.
-  Perform hand hygiene and put on PPE, if indicated.
- Expose the patient's chest wall so that the stethoscope can be placed directly on the skin of the chest wall.
- One watch with a sweep second hand is placed, so that both nurses can read it simultaneously.
- The nurses determine where they can best hear and feel the pulse and decide on a time to start counting, such as when the second hand on the watch is at a specified place (e.g., the number 12).
- Both nurses count for 1 full minute and record their counts. The difference between the apical and radial pulse rates is the pulse deficit.
-  Remove PPE, if used. Perform hand hygiene.

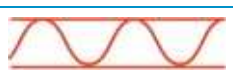
Box 26-4 **Factors Affecting Respiratory Rate, Depth, and Movements**

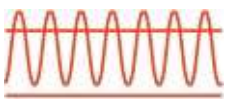
- **Age:** The respiratory rate decreases with age, ranging from a normal range of 30 to 60 breaths/min in a newborn to 12 to 20 breaths/min in an adult.
- **Exercise:** Exercise increases respiratory rate and depth.
- **Acid–base balance:** Alterations in acid–base balance (especially acidosis) commonly result in increased

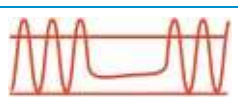
rate and depth of respirations (hyperventilation).

- **Brain lesions:** Lesions of the brain (such as hemorrhage or tumors) or brainstem can cause a change in both the depth and rate of respirations, most commonly manifested as Cheyne–Stokes respirations.
- **Increased altitude:** As an adaptation to higher altitudes, healthy people may exhibit Cheyne–Stokes respirations, especially when asleep. Higher altitudes also increase respiratory rate and depth prior to adaptation by increasing hemoglobin levels.
- **Respiratory diseases:** Any alterations in the normal respiratory structures may result in changes in respiratory rate, depth, and patterns, most often manifested as difficult breathing, using accessory muscles of respiration (such as the intercostal muscles), and increased rate. The depth may be shallower. Smoking can alter the pulmonary airways, resulting in an increase in respiratory rate at rest.
- **Anemia:** Anemia, a decrease in oxygen-carrying hemoglobin, may result in an increased rate of respirations.
- **Anxiety:** Anxiety can cause sighing type respirations (increased depth) and increased rate.
- **Medications:** Medications—such as narcotics, sedatives, and general anesthetics—slow respiratory rate and depth. Other drugs, including amphetamines and cocaine, may increase rate and depth.
- **Acute pain:** Acute pain increases respiratory rate but may decrease respiratory depth.

Physiology of Respirations

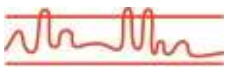






The rate and depth of breathing can change in response to tissue demands. These changes are brought about by the inhibition or stimulation of the respiratory muscles by the respiratory centers in the brain. Activation of the respiratory centers occurs via impulses from chemoreceptors located in the aortic arch and carotid arteries, via stretch and irritant receptors in the lungs, and via receptors in muscles and joints. An increase in carbon dioxide is the most powerful respiratory stimulant, causing an increase in respiratory depth and rate. The cerebral cortex of the brain allows voluntary control of breathing, such as when singing or playing a musical instrument. See Chapter 40 for a further discussion of respiratory physiology.

The rate and depth of inhalation and exhalation are normally smooth, easy, and without conscious effort. However, factors such as environmental changes and pathophysiologic alterations in various body systems may result in increases or decreases in respiratory rate and depth.



Factors Affecting Respirations

Many different factors affect respiratory rate and depth. These factors include exercise; respiratory and cardiovascular disease; alterations in fluid, electrolyte, and acid–base balances; medications; trauma; infection; pain; and emotions. Box 26-4 outlines the factors that affect respiratory rate, depth, and movements. Table 26-6 describes and illustrates various respiratory patterns.

Table 26-6 Patterns of Respirations

	DESCRIPTION	PATTERN	ASSOCIATED FEATURES
Normal	12–20 breaths/min Regular		Normal pattern
Tachypnea	>24 breaths/min Shallow		Fever, anxiety, exercise, respiratory disorders
Bradypnea	<10 breaths/min Regular		Depression of the respiratory center by medications, brain damage
Hyperventilation	Increased rate and depth		Extreme exercise, fear, diabetic ketoacidosis (Kussmaul's respirations)
Hypoventilation	Decreased rate and depth; irregular		Overdose of narcotics or anesthetics
Cheyne–Stokes respirations	Alternating periods of deep, rapid breathing followed by periods of		Drug overdose, heart failure, increased intracranial pressure,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	apnea; regular		renal failure
Biot's respirations	Varying depth and rate of breathing, followed by periods of apnea; irregular		Meningitis, severe brain damage

Normal Respiratory Rate

Under normal conditions, healthy adults breathe about 12 to 20 times each minute; infants and young children breathe more rapidly (see Table 26-1 on page 718) (Hess et al., 2021). Normal, unlabored respiration is called **eupnea**. The relationship of one respiration to four heartbeats is fairly consistent in healthy people.

Think back to **Noah Shoolin**, the 2-year-old brought to the emergency department. The nurse would anticipate that the child's respiratory rate would be increased most likely as a result of his screaming and emotional upset.

Increased Respiratory Rate

Tachypnea, an increased respiratory rate of more than 24 breaths per minute (breaths/min), may occur in response to an increased metabolic rate, such as when a person has a fever. Cells require more oxygen at this time and produce more carbon dioxide that must be removed. Tachypnea may be present in patients who have hypoxia (decreased oxygen to body tissues) and who have pain in the thoracic area. An increase in both the rate and depth of respirations is **hyperventilation**. Hyperventilation may result from hypoxia, anxiety, exercise, or metabolic acidosis (Jensen, 2019). Respiratory diseases such as acute pneumonia may cause tachypnea or hyperventilation.

Decreased Respiratory Rate

Bradypnea, a decrease in respiratory rate, less than 10 breaths/min. Bradypnea may result from increased intracranial pressure, neurologic disease, or sedation (Jensen, 2019). Certain drugs, such as opioids (e.g., morphine, hydromorphone), can depress the respiratory rate, as well as respiratory depth. **Hypoventilation** refers to shallow, slow respiration and may be related to increased intracranial pressure or sedation (Jensen).

Respiratory Depth and Rhythm

The depth of respirations normally varies from shallow to deep. The depth of each respiration is about the same when resting or sleeping. Periodically, each person automatically inhales deeply (sighs), filling the lungs with more air than with the usual depth of respiration.

Respiratory rhythm is the pattern of the breaths and the intervals between them. Respiratory rhythm is normally regular; the breaths and the pauses between occur at evenly spaced intervals. An irregular respiratory rhythm occurs when the breaths and pauses between beats occur at unequal, varied intervals.

Abnormal breathing patterns with alterations in depth, rate, and rhythm include Cheyne–Stokes respirations, associated with cerebral vascular disease and severe traumatic brain injuries, and Biot's respirations, associated with severe brain stem injury and meningitis (Hess et al., 2021). Table 26-6 describes and illustrates these two abnormal breathing patterns.

There are additional terms used to describe the nature of respirations. **Apnea** refers to periods during which there is no breathing. Apnea can be caused by an obstructive defect or be mediated by the central nervous system (Hess et al., 2021). Without intervention, death will occur within a few minutes of onset of apnea (Hess et al.). **Dyspnea** is difficult or labored breathing (shortness of breath). Dyspnea may be the result of heavy exercise or exertion or from a health condition. Dyspnea can be perceived only be the person experiencing it and is characterized by an increased effort to breathe (Hess et al., 2021). A situation in which a patient can breathe more easily and most comfortably in an upright position, but experiences shortness of breath when lying flat, is known as **orthopnea**. While a person is sitting or standing, gravity lowers organs in the abdominal cavity away from the diaphragm. This gives the lungs more room for expansion within the chest, allowing the intake of more air with each breath. Orthopnea may be associated with pulmonary edema, heart disease, and various chronic respiratory diseases, such as chronic obstructive pulmonary disease

(COPD) (Hess et al., 2021; Hinkle & Cheever, 2018).

Assessing Respirations

The nurse assesses respiratory rate (breaths per minute), depth (deep or shallow), and rhythm (regular or irregular) by inspection (observing and listening) or by listening with the stethoscope. Other methods of assessing respiratory effectiveness include using a pulse oximeter to determine oxygenation of blood and monitoring arterial blood gas results. A description of a pulse oximeter and a procedure for using it are found in Chapter 40. Arterial blood gas monitoring is discussed in Chapter 41. Skill 26-3 (on pp. 757–759) describes how to assess the respiratory rate. Further assessments of respirations are described in Chapters 27 and 40.

BLOOD PRESSURE

Blood pressure refers to the force of the moving blood against arterial walls. Maximum blood pressure is exerted on the walls of arteries when the left ventricle of the heart contracts and pushes blood through the aortic valve into the aorta at the beginning of systole. The pressure rises as the ventricle contracts (systole) and falls as the heart relaxes (diastole). This continuous contraction and relaxation of the left ventricle creates a pressure wave that is transmitted through the arterial system (Norris, 2019). The highest pressure, created during ventricular contraction, is the **systolic pressure**. When the heart rests between beats during ventricular diastole, the pressure drops. The lowest pressure present on arterial walls at this time is the **diastolic pressure**. The difference between the systolic and diastolic pressures is called the **pulse pressure**. Additional information about the function of the heart is discussed in Chapter 40.

Stroke volume and heart rate determine cardiac output (discussed in Chapter 40). Cardiac output and peripheral resistance determine both systolic and diastolic pressures. Peripheral resistance reflects the viscosity (thickness of the blood) and the changes in the radius of the arterioles.

Blood pressure is measured in millimeters of mercury (mm Hg) and is recorded as a fraction. The numerator is the systolic pressure; the denominator is the diastolic pressure. For example, if the blood pressure is 120/80 mm Hg, 120 represents the systolic pressure, and 80 represents the diastolic pressure. The pulse pressure, in this case, is 40 mm Hg.

Physiology of Blood Pressure

Arterial walls contain elastic tissue that allows them to stretch and distend (called compliance) as blood enters with each ventricular contraction. When the heart rests between each beat, the walls of the arteries return to their original position (recoil), although pressure in them does not drop to zero. The arterioles offer resistance to the pressure of the blood and keep the blood entering the capillaries in a continuous flow rather than in spurts. Therefore, the elasticity of the arterial walls, in addition to the resistance of the arterioles, helps to maintain normal blood pressure. With increased age, the walls of arterioles become less elastic, which interferes with their ability to stretch and dilate. This can subsequently limit adequate blood flow and contribute to rising pressure within the vascular system.

Although blood moves through the circulatory system from areas of higher pressure to areas of lower pressure, blood pressure is controlled by various short- and long-term mechanisms. These mechanisms regulate the blood pressure so that blood flow and blood pressure remain relatively constant.

Short-Term Regulation of Blood Pressure

The mechanisms for short-term blood pressure regulation (occurring over minutes or hours) are primarily neural (nerve) and humoral (pertaining to body fluids). These mechanisms correct temporary changes in pressure that occur during activities such as changing position or exercising and are also responsible for maintaining blood pressure during life-threatening situations. In addition, increased cardiac output (from a stronger contraction and increased stroke volume) results in an increased blood pressure while a weak contraction of the heart with decreased cardiac output causes a decrease in blood pressure.

The neural centers for blood pressure regulation are located in the brain in an area called the cardiovascular center. The cardiovascular center transmits parasympathetic impulses to the heart via the vagus nerve and sympathetic impulses to the heart and blood vessels via the spinal cord and peripheral sympathetic nerves. Stimulating the vagus nerve slows the heart rate; sympathetic stimulation increases the heart rate.

Pressure-sensitive receptors, called baroreceptors, are located in the heart and walls of arteries (such as the aortic arch and carotid). They are stimulated by changes in stretch of the blood vessel as blood pressure changes and send impulses to the cardiovascular center to initiate the appropriate changes in heart rate and vascular smooth muscle. For example, blood pressure normally decreases when rising from a lying to an upright position, resulting in decreased stretch of baroreceptors. In response, heart rate and peripheral vascular resistance increase to raise blood pressure. During life-threatening situations, such as a serious hemorrhage, the same mechanisms are activated.

Many different humoral mechanisms, along with hormones, also help regulate blood pressure. Epinephrine, a sympathetic neurotransmitter, is released by the adrenal gland to increase heart rate and contractility, thereby increasing cardiac output. The renin–angiotensin–aldosterone system, through angiotensinogen II, causes vasoconstriction in the arterioles. This leads to increased peripheral vascular resistance as a short-term mechanism, and also increases sodium

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

and water retention by the kidneys to increase circulatory fluid volume, thus increasing blood pressure as a long-term mechanism (see discussion in the next section). Vasopressin (antidiuretic hormone [ADH]) is released from the posterior pituitary when stimulated by decreased blood volume and blood pressure, or by an increased osmolality of body fluids. It has a direct vasoconstricting effect on blood vessels, increasing peripheral resistance.

Long-Term Regulation of Blood Pressure

Certain long-term mechanisms are responsible for the ongoing regulation of blood pressure. These mechanisms regulate extracellular fluid volume through the kidneys. They function by regulating blood pressure for an individual person's equilibrium point. Arterial pressure rises when the body contains too much extracellular fluid. In response, increased amounts of sodium and fluid are excreted by the kidneys to return the blood pressure to the person's equilibrium point. When blood pressure decreases due to decreased extracellular fluid, the opposite effect occurs. Extracellular fluid volume regulates blood pressure directly by increasing cardiac output and renal blood flow and indirectly by autoregulation of blood flow, in which autoregulatory mechanisms redirect blood flow to various blood tissues.

Factors Affecting Blood Pressure

A single blood pressure measurement is not necessarily significant because of the many factors that influence blood pressure. Box 26-5 lists factors that commonly cause variations in blood pressure.

Normal Blood Pressure

Studies of healthy people indicate that blood pressure can be within a wide range and still be normal. Because of individual differences, it is important to know the normal blood pressure range of a particular person. A rise or fall of 20 to 30 mm Hg in a person's blood pressure is significant, even if it is within the generally accepted normal range. Although blood pressure varies constantly, sustained long-term changes are not considered normal. Normal blood pressure is defined as a systolic pressure <120 mm Hg and diastolic pressure <80 mm Hg (Whelton et al., 2018). Table 26-7 identifies the categories for blood pressure levels in adults.

Increased Blood Pressure

Many factors influence blood pressure; a single elevated blood pressure measurement is not necessarily significant. Patients may have elevated blood pressure levels as a result of various factors, including pain, anxiety, and acute health conditions (refer to Box 26-5). **Hypertension**, one of the most common health problems, is blood pressure that is above normal for a sustained period. A diagnosis of hypertension is made when the systolic pressure is 130 mm Hg or higher or the diastolic pressure is 80 mm Hg or higher, based on the average of two or more readings obtained on two or more occasions to estimate the patient's level of blood pressure (Whelton et al., 2018). The guidelines related to high blood pressure in adults were updated in 2017 to reflect a lower definition of high blood pressure to account for complications that can occur at lower pressure numbers, and to allow for earlier intervention (Whelton et al., 2018). These changes in the definition of hypertension will result in almost half of the U.S. adult population (46%) having high blood pressure, with the greatest impact expected among younger people (Whelton et al., 2018). The prevalence of hypertension is greater in African American and Hispanic adults than in White adults (Whelton et al., 2018). Elevated blood pressure also progressively increases with age (Whelton et al., 2018). Hypertension is a major risk factor for cardiovascular disease, cerebral vascular accident (CVA) (stroke), myocardial infarction (MI), heart failure (HF), peripheral vascular disease, and abdominal aortic aneurysm (Whelton et al., 2018). It is called a "silent killer" because there are often few symptoms beyond increased blood pressure (World Health Organization [WHO], 2019). Refer to Table 26-7 for blood pressure categories.

Box 26-5 Factors Contributing to Blood Pressure Variations in Healthy People

- **Age:** The older adult has decreased elasticity of the arteries, which increases peripheral resistance and, therefore, increases blood pressure.
- **Circadian rhythm:** Normal fluctuations occur during the day. The blood pressure is usually lowest on arising in the morning. Blood pressure has been noted to rise as much as 5 to 10 mm Hg by late afternoon, and gradually falls again during sleep.
- **Biologic sex:** Women usually have lower blood pressure than men of the same age until menopause.
- **Food intake:** Blood pressure increases after eating food.
- **Exercise:** Systolic blood pressure rises during periods of exercise and strenuous activity.
- **Weight:** Blood pressure is usually higher in people who are obese than in those who are thin.
- **Emotional state:** Emotions, such as anger, fear, excitement, and pain, generally cause the blood pressure to rise, but the pressure falls to normal when the situation passes.
- **Body position:** Blood pressure tends to be lower in a prone or supine position than when sitting or standing.

- **Race:** Race is a factor in increased blood pressure (hypertension), which is more prevalent and more severe in African American men and women.
- **Drugs/Medications:** Oral contraceptives cause a mild increase in blood pressure in many women.

Table 26-7 Categories for Blood Pressure Levels in Adults (Ages 18 and Older)

CATEGORY	BLOOD PRESSURE LEVEL (mm Hg)		
	Systolic		*Diastolic*
Normal	<120	*and*	<80
Elevated	120–129	*and*	<80
Hypertension Stage 1	130–139	*or*	80–89
Hypertension Stage 2	≥140	*or*	≥90
Hypertensive crisis	>180	*and/or*	>120

(2018). 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the prevention, detection, evaluation, and management of high blood pressure in adults: A Report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines. *Hypertension*, *71*(6), e13–e115. https://doi.org/10.1161/HYP.0000000000000065

The basis for hypertension is thought to be dysfunction of the neurohormonal system. Over activation of both angiotensin and aldosterone result in an increase in blood pressure. Over time, this sustained increase results in a permanent remodeling and thickening of the blood vessels. As a result, there is increased peripheral resistance and a back-up of pressure to organs affected by the vascular system, such as the brain, heart, and kidneys. Disorders resulting from hypertension include those previously identified as well as thickening of the myocardium, enlargement of the ventricles, and kidney damage (chronic kidney disease or kidney failure).

There are many risk factors for the development of hypertension in adults. Significant risks are a family history of hypertension, race, aging, obstructive sleep apnea, and metabolic disorders such as metabolic syndrome, type 2 diabetes mellitus, obesity, and high cholesterol (Hinckle & Cheever, 2018). Lifestyle risk factors include a sedentary lifestyle; excessive alcohol consumption; and high dietary intake of salt, fats, and calories (Hinckle & Cheever, 2018).

Remember **Mrs. Renfrow**, the wife of a man who is overweight and diagnosed with hypertension? The nurse would need to incorporate information about various risk factors for developing hypertension as well as information about risk related to hypertension in the teaching plan for Mrs. Renfrow and her husband.

Promoting Health Literacy

IN PATIENTS WITH HYPERTENSION

Patient Scenario

Harry Miller, 66 years old, went to his primary health care provider for his annual health assessment. He had gained 15 lb in the past year. When the office nurse took his blood pressure, it was 166/92 mm Hg. The nurse took Mr. Miller's blood pressure again and then repeated it later after his health assessment was completed. Although the reading varied by a few points, it remained consistently high. Mr. Miller was obviously surprised at having hypertension, because he said, "It has never been this high before. There must be something wrong with your machine." His health care provider tried to discuss the need for

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

changes in his lifestyle as well as the need to take the medication prescribed for his blood pressure, but Mr. Miller said he had no questions and rushed out of the examining room.

Nursing Considerations: *Tips for Improving Health Literacy*

Provide Mr. Miller with printed literature about high blood pressure, including causes and risks. Explain that it is important to control his high blood pressure to prevent serious risks, such as heart attack and stroke. Urge Mr. Miller and his wife to talk to a dietitian about a nutritious diet that would help him lose weight; contains recommended servings of fiber, fruits, and vegetables; and contains less salt. Explain the action of the prescribed medication and the importance of taking the medication to reduce and control his blood pressure. Teach Mr. Miller and his wife about home blood pressure monitoring (HBPM). Encourage Mr. Miller to make an appointment to return to the office on a regular basis and to be prepared to ask his provider the following three questions:

- What is my main problem?
- What do I need to do?
- Why is it important for me to do this?

What additional measures can you take to help maintain health literacy in this patient and his wife? What other measures would be helpful for Mr. Miller if he did not speak English, could not read, or had other learning deficits?

Hypertension can be controlled by medications and lifestyle changes. Some of the categories of antihypertensive medications include diuretics (to decrease fluid volume), angiotensin-converting enzyme (ACE) inhibitors (to prevent vasoconstriction and aldosterone release by blocking the conversion of angiotensin I to angiotensin II), angiotensin II receptor blockers (ARB) (by selectively binding with the angiotensin II receptors in vascular smooth muscle and the adrenal cortex to block vasoconstriction and the release of aldosterone), vasodilators and calcium channel blockers (to relax smooth muscles of arterioles and decrease peripheral vascular resistance), and beta-adrenergic blockers (to block sympathetic stimulation and decrease cardiac output) (Karch, 2020). Lifestyle changes include weight loss for overweight or obese patients; a heart healthy diet (reduced sodium; low in saturated fat and total fat; increase in fruits, vegetables, and grains); limiting alcohol intake (no more than two alcohol drinks per day for men and no more than one for women); managing and coping with stress; and engaging in regular physical activity (Whelton et al., 2018). Nurses can influence the health of the public through screenings, education, and referrals. See Promoting Health Literacy in Patients with Hypertension for more information.

Screening for hypertension is recommended in children beginning at the age of 3 years. False elevations in pressures can result from anxiety or caffeine intake; checking multiple measurements over time is recommended (American Academy of Pediatrics, 2020). Hypertension is diagnosed if a child has auscultatory-confirmed blood pressure readings ≥95th percentile on 3 different visits (American Academy of Pediatrics, 2020). Lifestyle interventions, related to nutrition, sleep, and physical activity are initiated initially, with close monitoring. Refer to the Clinical Practice Guideline from the American Academy of Pediatrics (2020) for additional discussion related to and treatment of pediatric hypertension (Flynn et al., 2017).

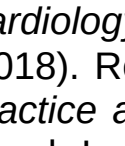
Decreased Blood Pressure

Hypotension is below-normal blood pressure. Hypotension is blood pressure that is lower than 90/60 mm Hg (NHLBI, n.d.). The body uses the previously discussed mechanisms to maintain consistent blood pressure. Hypotension occurs primarily as a result of the inability of the body's control mechanisms to maintain or return blood pressure back to normal or the inability to do it quickly enough. Hypotension may also occur as a result of pathology (disease process), such as Parkinson disease (related problems with the autonomic nervous system contribute to low blood pressure) (NHLBI). Pathologic hypotension might result from vasodilation of the arterioles, failure of the heart to function as an effective pump, or loss of blood volume (such as with a hemorrhage). Hypotension can be a side effect of some medications, including antihypertensives, certain antidepressants, antianxiety medication, and analgesics. A consistently low blood pressure is normal in some adults, with no signs or symptoms. Hypotension is a concern if it causes signs or symptoms or is linked to a disease or health process. The nurse should immediately communicate assessments of hypotension and associated symptoms of dizziness, tachycardia, pallor, syncope, increased sweating, blurred vision, nausea, and confusion.

Orthostatic hypotension (postural hypotension) is a common form of low blood pressure (Cheshire, 2019). It results from an inadequate physiologic response to postural (positional) changes in blood pressure. *Classical orthostatic hypotension* is a sustained decrease in systolic blood pressure of ≥20 mm Hg or a decrease in diastolic blood pressure of ≥10 mm Hg *within* 3 minutes of standing or during a head-up tilt test to at least 60 degrees (Freeman et al., 2018). *Delayed orthostatic hypotension* (DOH) is a sustained reduction in blood pressure that occurs *after* 3 minutes of standing or upright tilt (Freeman et al.). *Initial orthostatic hypotension* is a transient reduction in systolic blood pressure of ≥40 mm Hg and/or a transient decrease in diastolic blood pressure of ≥20 mm Hg *within* 15 seconds of standing (Freeman et

al., 2018). Orthostatic hypotension may be acute or chronic as well as symptomatic or asymptomatic.

Orthostatic hypotension occurs when a person rises to an erect position, either supine to sitting, supine to standing, or sitting to standing. It is caused by dehydration or blood loss; problems of the neurologic, cardiovascular, or endocrine systems; and/or use of certain classes of medications. Orthostatic hypotension may be associated with dizziness, confusion, lightheadedness, blurred vision, weakness, fatigue, nausea, tachycardia, palpitations, and headache, but the presence of symptoms is not necessary for the diagnosis (Freeman et al.). Symptoms occur with postural change, are exacerbated by standing, and relieved by sitting or lying flat (Freemen et al.). Aging is also a risk factor for developing orthostatic hypotension (Godbole & Aggarwal, 2018). Older adults who experience orthostatic hypotension are at increased risk for falls (McDonald et al., 2017). Orthostatic blood pressure measurements should be included in the clinical evaluation of all older adults (Lipsitz, 2017).



Several nonpharmacologic interventions may be used to control or prevent orthostatic hypotension. Educate patients about the need to arise and move about slowly, especially after a period of bed rest (Godbole & Aggarwal, 2018). When ambulating patients after surgery or prolonged bed rest, first raise the head of the bed, then assist the patient to a sitting position on the side of bed (often called "dangling") for a few minutes to assess for dizziness or faintness, and then assist to a standing position. If the patient becomes dizzy or feels faint, return the patient to bed and place in a supine position, which restores blood flow to the brain. Administer contributing medications at bedtime if possible, especially antihypertensives. Patients should ensure adequate hydration. Compression stockings and abdominal compression support garments may be implemented (Godbole & Aggarwal, 2018). There are also numerous medications that are used to treat orthostatic hypotension, with the goal to alleviate symptoms and avoid adverse effects, not necessarily restore normotension (Freeman et al., 2018). Guidelines for Nursing Care 26-5 describes one method to obtain blood pressure measurements to assess for orthostatic hypotension.

Guidelines for Nursing Care 26-5

Assessing Orthostatic Hypotension

Use the following guidelines to assess for orthostatic hypotension:

Assess for signs and symptoms of hypotension, such as dizziness, lightheadedness, pallor, diaphoresis, or syncope throughout the procedure. If the patient is attached to a cardiac monitor, assess for arrhythmias. Immediately return the patient to a supine position if symptoms appear during the procedure. Do not have the patient stand if symptoms of hypotension occur when the patient is sitting.

-  Perform hand hygiene and put on PPE, if indicated.
- Lower the head of the bed. Place the bed in a low position.
- Ask the patient to lie in a supine position for 3 to 10 minutes. At the end of this time, take initial blood pressure and pulse measurements.
- Assist the patient to sit on the side of the bed with legs dangling. After 1 to 3 minutes, take the blood pressure and pulse measurements.
- Assist the patient to stand (unless contraindicated). Thirty seconds after standing, take blood pressure and pulse measurements, then a second set of measurements at 60 seconds (Godbole & Aggarwal, 2018). Wait 1 minute and take a third set of measurements, and a fourth set after one additional minute, for a total of 3 minutes (Godbole & Aggarwal).
- Record the measurements for each position. A decrease in systolic blood pressure of ≥20 mm Hg or a decrease in diastolic blood pressure of ≥10 mm Hg within 3 minutes of standing when compared with blood pressure from the sitting or supine position is significant for orthostatic hypotension (Godbole & Aggarwal). In patients with hypertension (supine systolic BP ≥160 mm Hg), a drop of systolic BP of at least 30 mm Hg is more appropriate (Godbole & Aggarwal).
-  Remove PPE, if used. Perform hand hygiene.

Assessing Blood Pressure

Measurement of blood pressure is an important part of vital sign measurement; identification of a patient's baseline status; and identification of changes in a patient's status. Accurate measurement of blood pressure (BP) is essential for the diagnosis and management of hypertension (Mutner et al., 2019). Blood pressure measurements should be obtained as two or more readings on two or more occasions and the measurements averaged to estimate the person's level of blood pressure (Whelton et al., 2018).

Blood pressure may be assessed with different types of devices and at several locations on the body. The nurse must know the appropriate equipment to use, including choosing the appropriate blood pressure cuff; how to accurately obtain the measurement; how to describe the sounds that are heard during the auscultatory method of measurement; and which site to choose in order to accurately assess blood pressure.

The auscultatory method has been the standard clinical method of measurement of blood pressure using a stethoscope and sphygmomanometer to detect the appearance and disappearance of the Korotkoff sounds, which represent systolic and diastolic blood pressure. Advances in technology have contributed to increased accuracy in automated, electronic oscillometric devices for measurement of BP; there is growing evidence supporting the use of these devices in clinical settings (Whelton et al., 2018). Many oscillometric devices have been validated that allow accurate BP measurement while reducing human errors associated with the auscultatory approach (Muntner et al., 2019; Myers et al., 2018). "Out-of-office" measurement of blood pressure can contribute to confirmation and improved management of hypertension (Muntner et al., 2019; Whelton et al., 2018). Ambulatory blood pressure monitoring (ABPM) and home blood pressure monitoring (HBPM) (self-monitoring) are two methods used to obtain blood pressure measurements outside the clinical practice areas. Systolic BP pressure can be estimated with a Doppler ultrasound device (described in the discussion of pulse measurement) or by palpation. Direct electronic measurement of BP is accomplished through direct arterial access and used primarily in intensive care areas.

Blood pressure measurement results are most commonly recorded with two numbers, written as a fraction. The first number in the fraction represents the systolic pressure—for example, if the blood pressure reading is 120/80 mm Hg, 120 is the systolic pressure. The second number in the fraction represents the diastolic pressure, in this case, a diastolic pressure of 80 mm Hg.

Table 26-8 Recommended Blood Pressure Cuff Sizes

CUFF SIZE	CUFF BLADDER DIMENSIONS (cm)	ARM CIRCUMFERENCE[a] (cm)
Neonates, Infants, Children	Cuff bladder length should encircle 80–100% of arm Cuff bladder width-to-arm circumference ration of 0.45–0.55	
Small adult size	12 × 22	22–26
Adult size	16 × 30	27–34
Large adult size	16 × 36	35–44
Adult thigh size	16 × 42	45–52

[a]Select a blood pressure cuff that has a bladder length 75%–100% of the arm circumference and a width that is 37%–50% of the arm circumference.

Recommendations for blood pressure measurement in humans and experimental animals. Part 1: Blood pressure measurement in humans: A statement for professionals from the subcommittee of professional and public education of the American Heart Association Council on High Blood Pressure Research. *Circulation*, *111*(5), 697–716. https://doi.org/10.1161/01.CIR.0000154900.76284.F6

Blood Pressure Cuffs

The initial step in measuring blood pressure is determining the appropriate cuff size. Blood pressure cuffs are used in both the auscultatory and oscillometric methods of BP measurement. The cuff contains an airtight, flat, rubber bladder covered with cloth. Selecting a cuff of the proper size (ranging from neonate to adult thigh) is essential to obtain an accurate blood pressure reading. The correct cuff should have a bladder length that is 75% to 100% of the patient's arm circumference and a width that is 37% to 50% of the arm circumference, with a length-to-width ratio of 2:1 (Muntner et al., 2019).

The cuff should be pulled taut when placed on the bare limb, with comparable tightness at the top and bottom edges of the cuff. Check the tightness: one finger should fit easily at the top and bottom of the cuff; two fingers should fit but be very snug (Muntner et al., 2019).

Incorrect cuff size contributes to the most frequent error in measurement in nonacute care settings (Muntner et al., 2019). *If the cuff is too narrow*, the reading could be erroneously high because the pressure is not evenly transmitted to the artery. This occurs, for example, when an average-sized cuff is used on an obese person. Based on size and shape dimensions, an appropriately sized cuff as closely aligned to the AHA's guidelines as possible should be selected to ensure accurate readings in this patient population. A cone-shaped cuff may be necessary to accommodate the size and shape of the arm for these patients (Muntner et al., 2019). If a cuff cannot be fitted correctly, the wrist should be used (Muntner et al., 2019). Refer to the discussion Sites of Assessing the Blood Pressure later in this section. *If a cuff is too wide* (e.g., using an adult cuff on the arm of a child), the reading may be erroneously low because pressure is dispersed over a disproportionately large surface area. Recommendations by the AHA for the selection of an appropriately sized cuff are given in Table 26-8.

Think back to **Mrs. Renfrow**, the wife of a patient with hypertension who is overweight. The nurse would need to caution Mrs. Renfrow to make sure that the device she uses to measure her husband's blood pressure is sized adequately. Otherwise, the readings may be erroneous, possibly leading to inappropriate management based on inaccurate readings or a false sense of security that the hypertension is being controlled.

Depending on the product, cuffs may be disposable or reusable. They are closed around the limb with contact closures, such as nylon fabric that can be fastened to itself with Velcro. One or two tubes are attached to the bladder within the cuff, depending on the device used. Cuffs for the device used for the auscultatory method (sphygmomanometer) have two tubes; one is connected to a manometer and a second tube is attached to a bulb used to inflate the bladder in the cuff. Cuffs used with the oscillometric device have one tube connecting the cuff to the device. The cuff bladder is inflated enough to obstruct the flow of blood through the artery. A valve on the cuff bulb allows the cuff to be deflated while the pressure is being read during use of the auscultatory device.

Patient Preparation for Blood Pressure Measurement

Blood pressure measurement should take place in a quiet environment. The patient should not have consumed caffeine, exercised, or smoked for 30 minutes before the measurement (Muntner et al., 2019). The patient should not talk or move during the procedure. The patient may be supine or sitting; systolic BP may be as much as 10 mm Hg higher and diastolic BP as much as 5 mm Hg higher in the supine than the seated position (Tolonen et al., 2015, as cited in Muntner et al., 2019). In the supine position, the patient's arm should be supported with a pillow at heart level (Muntner et al., 2019). When sitting, the patient's arm should be supported on a table at heart level or held up by the health care provider (midpoint of the sternum). The patient's feet and back should be supported as well (Whelton et al., 2018). Adequate support and proper positioning prevent inaccurately high readings (Muntner et al., 2019). Lack of back support can lead to an increase in systolic readings of up to 15 mm Hg and diastolic reading up to 6 mm Hg (Pan et al., 2014, as cited in Muntner et al., 2019). Legs should not be crossed during BP measurement to avoid raising of the systolic BP by as much as 8 mm Hg and diastolic BP by as much as 5 mm Hg (Liu et al., 2016, as cited in Muntner et al., 2019).

Errors in Blood Pressure Measurement

Regardless of the method used to measure blood pressure, health care providers must ensure the use of validated and calibrated devices and use careful, accurate technique to avoid errors in BP measurement (Muntner et al., 2019; Pickering et al., 2005; Whelton et al., 2018). Retraining of health care professionals every 6 months to 1 year has been suggested to ensure accurate measurement (Muntner et al., 2019). Box 26-6 identifies potential sources of blood pressure

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

measurement error.

Box 26-6 Sources of Error in Blood Pressure Measurement

- Use of noncalibrated, nonvalidated, nonmaintained device
- Use of a cuff of incorrect size
- Patient movement during measurement
- Patient talking during the measurement
- Incorrect placement and/or orientation of the cuff
- Incorrect positioning of the patient
- Use of inaccurate measurement technique
  - Incorrect positioning of the limb used for measurement
  - Inflation of cuff that is too rapid
  - Deflation of cuff that is too rapid (faster than 2 to 3 mm Hg per second)
- Environmental noise
- Failure to allow for a rest period prior to measurement
- Incorrect interpretation
- Reliance on blood pressures measured at a single occasion

Oscillometric Method of Measurement

Automated, electronic oscillometric blood pressure monitors determine blood pressure by analyzing the sounds of blood flow or measuring the amplitude of the oscillations (fluctuations) in blood flow upon deflation or inflation of the cuff (Fig. 26-4 on page 740). These devices can be set to take and record blood pressure readings at preset intervals. As previously discussed, there has been a shift away from manual auscultatory BP measurement to the use of oscillometric measurement method, supported by improved device technology, as well as the recommendation to obtain multiple BP readings to increase accuracy (Muntner et al., 2019). Oscillometric devices are commonly used to measure BP in a variety of settings, including clinics, ambulatory, home, and acute care (Muntner et al., 2019). Calibration of devices at regular intervals, based on manufacturer guidelines, is recommended to ensure accuracy (Muntner et al., 2019). Health care providers must ensure use of validated and calibrated devices and use careful, accurate technique to avoid errors in BP measurement.

FIGURE 26-4. The electronic oscillometric blood pressure monitor reports systolic and diastolic blood pressure, as well as mean blood pressure. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

Many of these devices have additional integrated equipment, such as a thermometer and pulse oximetry, to perform multiple vital sign measurements.

Refer to Skill 26-4 on pp. 759–763 for a detailed description of the accurate use of the oscillometric method of BP measurement.

Auscultatory Method of Blood Pressure Measurement

The auscultatory method of measuring BP has been the traditional approach to measurement of systolic and diastolic blood pressure and remains an acceptable method for measuring blood pressure (Muntner et al., 2019). However, many

of the sphygmomanometers available for use are susceptible to error and loss of calibration and require frequent calibration to ensure accuracy (Muntner et al., 2019). In addition, accuracy of BP readings relies on precise measurement technique (Muntner et al.). There are numerous potential sources of BP error and the use of inaccurate measurement technique is common (Kallioinen et al., 2017). As mentioned previously, this method is being replaced more and more by the use of oscillometric devices in clinical practice (Muntner et al., 2019).

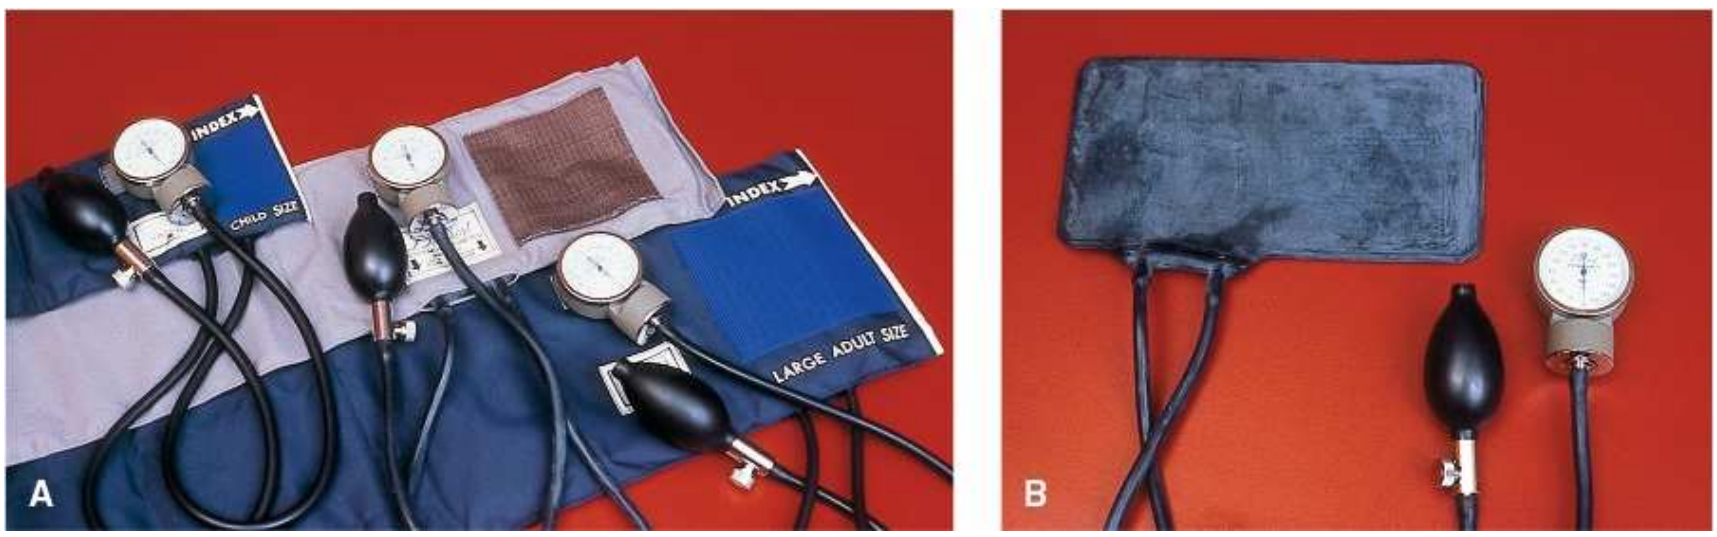

FIGURE 26-5. Sphygmomanometer. **A.** Three cuff sizes: a small cuff for a child or a small or frail adult, a normal-sized cuff, and a large adult cuff. A cuff sized for use on the thigh is also available. **B.** Parts of a sphygmomanometer. (*Source:* Part B used with permission from Weber, J. R., & Kelley, J. H. [2018]. Health assessment in nursing [6th ed.]. Wolters Kluwer, p. 135.)

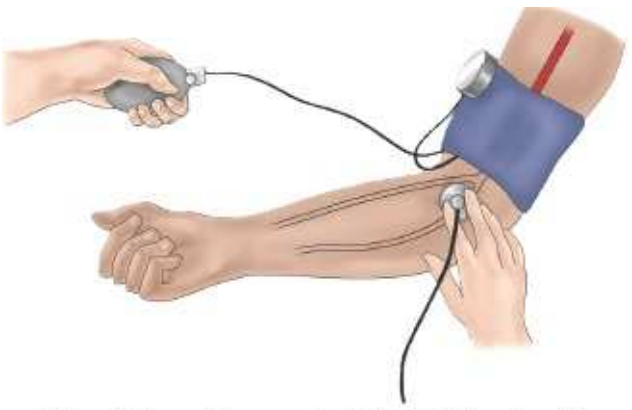
A sphygmomanometer, along with a stethoscope, is used to assess blood pressure in the auscultatory method of BP measurement. The sphygmomanometer consists of a cuff (with an air compartment), a pump, and the manometer (pressure dial) (Fig. 26-5). The BP cuff is placed on the patient's limb and inflated, causing the underlying artery to be occluded and flow to stop; as the cuff is gradually deflated, blood flow is reestablished, accompanied by sounds that can be heard with a stethoscope placed at a pulse site corresponding with the underlying artery (Muntner et al., 2019). The nurse listens to a series of these sounds when assessing the blood pressure using the auscultatory method. These sounds are called **Korotkoff sounds**, described and illustrated in Table 26-9. These sounds are only heard when using a stethoscope to assess blood pressure. In some adults, each of these sounds is distinct, whereas in others only the beginning and ending sounds are heard. It is important to determine facility policy for recording blood pressure sounds and to be consistent in taking and documenting the readings.

The first sound heard through the stethoscope, which is the onset of Phase I, represents the systolic pressure. It is recorded as the first number in the fraction—for example, if the blood pressure reading is 120/80 mm Hg, 120 is the systolic pressure. The second number, which represents the diastolic pressure (in this case, 80), notes the level at which the sounds disappear completely, Phase V. Read measurements to the nearest even number (nearest 2 mm Hg) (Flynn et al., 2017; Whelton et al., 2018). In situations in which sounds were heard all the way down to zero—for example, in pregnant women and patients with arteriovenous fistulas—the blood pressure recording would include phase IV (e.g., 112/62/0) (Flynn et al., Muntner et al., Pickering et al., Whelton et al., 2018).

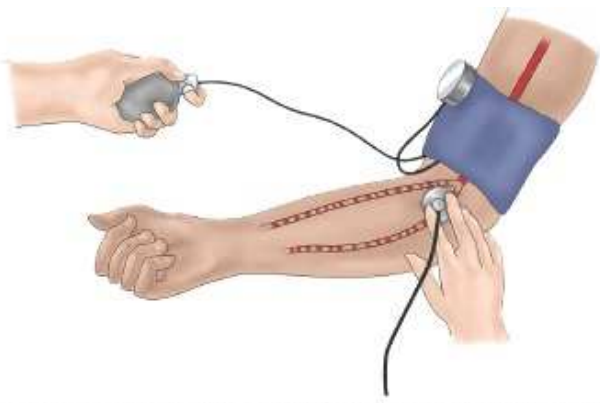
Refer to Skill 26-5 on pp. 763–768 for a detailed description of the accurate use of the auscultatory method of BP measurement.

Ambulatory Blood Pressure Monitoring



ABPM is a noninvasive, fully automated method of blood pressure measurement that allows for BP measurement to be recorded over an extended period of time, such as over 24 hours, while the patient is awake or asleep. The digital device consists of a cuff placed on the patient's arm, and the machine is small enough to be worn on a belt around the patient's waist. Readings are usually taken and recorded by the device every 20 to 30 minutes during the day and every hour at night (Cleveland Clinic, 2020). Patients must avoid bathing and swimming while wearing the device. ABPM may be used to supplement blood pressure readings obtained in nonacute care settings to detect abnormal fluctuations that may not be noted in single measurements. ABPM is useful in confirming a diagnosis of hypertension; identifying patterns in blood pressure measurements; and monitoring the effectiveness of antihypertensive drug therapy (Cleveland Clinic; Muntner et al., 2019). There is increased recognition of inconsistencies between office and out-of-office blood pressure readings, with office blood pressure readings often higher than ambulatory or home measurements (Muntner et al., 2019; Whelton et al., 2018). Studies have shown substantial differences in blood pressure when measured outside versus in the office or clinic setting (Muntner et al.). ABPM can be used to increase accuracy of BP readings and monitor blood pressure levels over time.

Table 26-9 Korotkoff Sounds



PHASE	DESCRIPTION	ILLUSTRATION
Phase I	Characterized by the first appearance of faint	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	but clear tapping sounds that gradually increase in intensity; the first tapping sound is the systolic pressure
Phase II	Characterized by muffled or swishing sounds; these sounds may temporarily disappear, especially in hypertensive people; the disappearance of the sound during the latter part of phase I and during phase II is called the ***auscultatory gap*** and may cover a range of as much as 40 mm Hg; failing to recognize this gap may cause serious errors of underestimating systolic pressure or overestimating diastolic pressure
Phase III	Characterized by distinct, loud sounds as the blood flows relatively freely through an increasingly open artery
Phase IV	Characterized by a distinct, abrupt, muffling sound with a soft, blowing quality
Phase V	The last sound heard before loss of all sounds; the pressure at which the last sound is heard is the second diastolic pressure

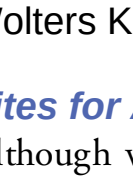
Blood flow interrupted by inflated cuff.

As the pressure in the cuff is released, blood starts flowing again and Korotkoff sounds are audible.

Cuff is completely deflated after Phase V, restoring complete blood flow.

Doppler Ultrasound

An indirect blood pressure measurement may be obtained with a Doppler ultrasound device, which amplifies sounds. This device is especially useful if the sounds are indistinct or are inaudible with a regular stethoscope. This method only provides an estimate of systolic blood pressure. See Guidelines for Nursing Care 26-6 (on page 742) for this assessment technique.



Direct Electronic Measurement of Blood Pressure

It is possible to measure blood pressure directly through the insertion of a thin catheter into an artery, most commonly the radial or femoral artery (an arterial line [A-line]) (Burns & Delgado, 2019). The tip of the catheter senses the pressure and transmits this information to a machine that displays the systolic pressure and diastolic pressure in a waveform. This technique is used primarily in intensive care areas.

Guidelines for Nursing Care 26-6

Assessing Blood Pressure Using a Doppler Ultrasound

-  Perform hand hygiene and put on PPE, if indicated.
- Select the appropriate limb for application of cuff.
- Have the patient assume a comfortable lying or sitting position with the appropriate limb exposed.
- Center the bladder of the cuff over the artery, lining the artery marker on the cuff up with the artery.
- Wrap the cuff around the limb smoothly and snugly, then fasten it. Do not allow any clothing to interfere with the proper placement of the cuff.
- Check that the needle on the aneroid gauge is within the zero mark. If using a mercury manometer, check to see that the manometer is in the vertical position and that the mercury is within the zero level with the gauge at eye level.
- Place a small amount of conducting gel on the Doppler transducer probe.

- Turn the Doppler on.
- Hold the Doppler device in your nondominant hand. Touch the probe lightly to the skin with the probe tip in the gel. Adjust the volume, as needed. Move the probe so it is perpendicular to the skin. Slowly move the Doppler tip around until you hear the pulse.
- Once the pulse is found using the Doppler, close the valve to the sphygmomanometer. Tighten the screw valve on the air pump.
- Inflate the cuff while continuing to use the Doppler on the artery. Note the point on the gauge where the pulse disappears.
- Pump the cuff another 20 to 30 mm Hg.
- Slowly open the valve on the manometer and deflate the cuff and note the reading for the systolic BP when the pulse returns.
- Repeat any suspicious reading, but wait at least 1 minute between readings to allow normal circulation to return in the limb. Deflate the cuff completely between attempts to check the blood pressure.
- Remove the Doppler tip and turn the Doppler off. Wipe excess gel off the patient's skin with tissue. Remove the cuff.
- Wipe off any gel remaining on the Doppler probe with a tissue. Clean the Doppler according to facility policy or manufacturer's recommendations.
- Return the Doppler to the charge base.
-  Remove PPE, if used. Perform hand hygiene.

Sites for Assessing the Blood Pressure

Although various sites may be used to assess the blood pressure, the brachial artery and the popliteal artery are most commonly used. Equipment has also been developed to measure blood pressure at the forearm; the radial site may be used with individuals who have very large upper arms or who are obese (Muntner et al., 2019). Some patients cannot have blood pressure measured in their upper arms because of obesity and/or various health conditions; blood pressure measurement may be obtained at their ankle (Sheppard et al., 2019). Refer to the accompanying Research in Nursing box addressing the relationship between arm and ankle blood pressure measurements.

ASSESSING BLOOD PRESSURE AT THE BRACHIAL ARTERY

The brachial artery is used most frequently for noninvasive blood pressure monitoring. It is recommended that blood pressure should be checked in each arm at an initial examination and that the arm with the higher blood pressure reading should be used for subsequent measurement (Williams et al., 2018, as cited in Muntner et al., 2019). It has been shown that most people have differences in blood pressure readings between arms. Persistent differences in measurements between arms may indicate coarctation of the aorta or upper extremity arterial obstruction (Muntner et al.). A brachial artery blood pressure assessment should not be taken on an arm with an intravenous line or with an arteriovenous fistula or shunt. Blood pressure assessment should also be avoided in the arm on the side of an axillary node dissection or mastectomy because the pressure may increase the risk of lymphedema developing in the affected arm.

The brachial artery must be palpated to identify its location; the BP cuff is placed on the arm with the center of the bladder length of the cuff in alignment with the brachial pulse. The lower end of the cuff should be 2 to 3 cm (Muntner et al.) above the antecubital fossa, allowing room for placement of the stethoscope.

Skill 26-4 (on pp. 759–763) describes how to assess the blood pressure using the auscultatory method at the brachial artery.

ASSESSING BLOOD PRESSURE AT THE RADIAL ARTERY

The radial artery is used to auscultate the Korotkoff sounds when assessing blood pressure in the forearm. The BP cuff is placed on the forearm and the stethoscope is placed over the radial artery at the wrist. Automated electronic oscillometric wrist monitors have been developed as well. However, evidence is conflicting on correlation of measurements from this site with upper arm measurements and the accuracy of measurements from this site (Arnold & McNaughton, 2018; Muntner et al., 2019). If this site is used, the wrist should be elevated and supported at the level of the heart (Muntner et al., 2019). Forearm measurements tend to be higher than the upper arm measurements (Halm, 2014).

Arm versus Leg/Ankle Blood Pressure Measurement

Assessment of vital signs is an important component of assessment in almost every health care setting. Blood pressure measurement is an essential element of this assessment. Standard practice includes obtaining this measurement in the upper arm, with the heart used as the reference for leveling. However, many treatments and health conditions limit the use of the arm for blood pressure measurements. The lower extremities may be considered as an alternative site. What is the relationship between blood pressure measurement in the arm and leg at the ankle? What are the implications of leg/ankle blood pressure measurement?

Sheppard, J. P., Albasri, A., Franssen, M., Fletcher, B., Pealing, L., Roberts, N., Obeid, A., Pucci, M., McManus, R. J., Martin, U., & British and Irish Hypertension Society. (2019). Defining the relationship between arm and leg blood pressure readings: A systematic review and meta-analysis. *Journal of Hypertension*, *37*(4), 660–670. https://doi.org/10.1097/HJH.0000000000001958

The objective of this systematic review and meta-analysis was to define the relationship between arm and leg blood pressure to inform the interpretation of leg blood pressure readings in routine clinical practice, in instances when arm readings are not possible. Articles were included in the systematic review if the study measured and reported arm and leg blood pressure measured in the supine position and/or the difference between the two sites. A total of 44 articles were included in the review. Mean values for arm/leg blood pressure difference and confidence intervals or standard deviations were entered into a meta-analysis. Readings taken at the ankle in the supine position were 16 to 18 mm Hg higher than those taken in the arm. The researchers concluded ankle blood pressure measurements and arm blood pressure measurements are not interchangeable, and measurement location must be taken into consideration. Based on the study results, the researchers suggested that, when using ankle measurements rather than measurements taken in the arm, health care providers should consider adding 15 mm Hg to the systolic treatment threshold for hypertension, effectively making the threshold 155/90 mm Hg.

Relevance to Nursing Practice

Blood pressure measurement is a frequently used assessment. It may be necessary to obtain measurements from alternate locations, based on patient circumstances. Location of measurement and circumstances must be documented as well as taken into account when the patient's arms are not available and ankle measurements are considered.

This site has been suggested as an alternative for obtaining blood pressure readings for individuals who are obese, as it is often difficult to obtain the appropriately sized cuff for the upper arm, given arm circumference and conical-shaped upper arms common in obesity. The conical shape of the upper arm makes it difficult to fit the cuff to the arm, increasing the likelihood of inaccurate blood pressure measurement (Halm, 2014). Measurement in the forearm is a possible solution to this problem (Muntner et al., 2019; Palatini, 2018).

ASSESSING BLOOD PRESSURE AT THE POPLITEAL ARTERY

When the patient's brachial artery is inaccessible and/or the use of the upper arm is contraindicated, the nurse can assess the blood pressure using the popliteal artery in the leg. The systolic pressure is normally 10 to 40 mm Hg higher at this site than the arm, although the diastolic pressure is the same (Jensen, 2019). The technique for assessment is outlined in Guidelines for Nursing Care 26-7 on page 744.

PALPATING THE BLOOD PRESSURE

Assessing the blood pressure through palpation requires only the use of the sphygmomanometer. The cuff is inflated 30 mm Hg above the point at which the pulsation in the artery disappears. As the air in the cuff is released, the nurse feels for the return of the pulse. Usually, no diastolic pressure is recorded because the artery continues to pulsate as long as blood flows through it.

DIAGNOSING ACTUAL OR POTENTIAL HEALTH PROBLEMS AND NEEDS

The assessment of the patient may lead to the identification of one or more actual or potential health problems and needs related to alterations in vital signs. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record. Examples of health problems and needs with related etiology and signs and symptoms can be found in Examples of Actual or Potential Health Problems and Needs: Altered Vital Signs (on page 744).

TEACHING VITAL SIGNS FOR SELF-CARE AT HOME

Patients and/or their family members/caregivers often need to check their own temperature, pulse, and/or blood pressure at home. Guidelines for teaching self-assessment are presented in Teaching Tips 26-1 (on pages 745–746).

Guidelines for Nursing Care 26-7

Assessing Blood Pressure at the Popliteal Artery

-  Perform hand hygiene and put on PPE, if indicated.
- Place the patient in the prone position, if possible. If that position is not possible, place the patient in the supine position, with the knee slightly flexed.
- Use a cuff that is specifically made for this assessment, or one that is large enough to make an accurate assessment.
- Place the cuff around the lower third of the thigh, centered over and 2.5 cm (1 inch) above the popliteal artery, with the bladder over the posterior of the midthigh (see figure).
- Follow the same procedure for auscultation as for the brachial artery.

Thigh blood pressure. (*Source:* From Jensen, S. [2019]. *Nursing health assessment. A best practice approach* [3rd ed.]. Wolters Kluwer.)

HBPM refers to regular measurement of BP by an individual in the patient's home or usual environment (Muntner et al., 2019; Stergiou et al., 2018; Whelton et al., 2018). HBPM is being increasingly recommended. Research has shown that readings at home are reliable, are often lower than those taken in a health care provider setting, contribute to better adherence treatment, and provide multiple readings taken over prolonged periods, giving a better picture of the patient's status and response to treatment (Muntner et al., 2019; Stergiou et al., 2018; Whelton et al., 2018). Patient education related to HBPM includes the rationale for its use, as well as steps to obtain an accurate pressure reading. It is important to ensure that an appropriate device is used by the patient (Whelton et al., 2018). Measurements are averaged to identify the mean home BP level. Patients should record readings as directed by their healthcare provider according to the recommended monitoring schedule. Many devices automatically store and average readings, and results can be downloaded or accessed with telemonitoring, eliminating errors related to a lack of or inaccuracy in patient documentation. Suggested guidelines for HBPM include:

Examples of Actual or Potential Health Problems and Needs

ALTERED VITAL SIGNS

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Impaired Comfort	Dehydration Illness Infection	Flushed skin, tachycardia, tachypnea, increase in body temperature above normal range, body aches, headache
Altered Tissue Perfusion	Hypertension, smoking, diabetes mellitus	Absent or diminished pulses, blood pressure changes in extremities, capillary refill time >3 seconds, altered skin characteristics
Altered Breathing Pattern	Anxiety, hyperventilation, pain, neurologic impairment	Alterations in rate/rhythm/depth of breathing, dyspnea, pain, cough, use of accessory muscles to breathe, pulse oximetry <93%

Source: Wolters Kluwer. Problem-based care plans. (2020). In Lippincott Advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

- Advising patients to buy validated oscillometric BP monitors that measure BP on the upper arm with an appropriate cuff size (Harvard Medical School, 2020; Stergiou et al., 2018).
- Explaining that home monitoring devices should be checked for accuracy every 1 to 2 years. Readings should be compared with auscultated measurement by a health care provider to ensure accuracy.
- Explaining that frequency of measurement is based on the individual patient's circumstances and intended outcomes.
- When HBPM is used for diagnosing hypertension, explaining that two readings are taken, at least 1 minute apart, while in a sitting position, in both the morning and at night, for a minimum of 3 days, with a preferred period of 7 days (Muntner et al., 2019; Stergiou et al., 2018).
- Instructing the patient to record measurements as directed to show to the health care provider.

Teaching Tips 26-1

SELF-CARE: MEASURING TEMPERATURE, PULSE, AND BLOOD PRESSURE

Health Topic	Teaching Tips	Why Is This Important?
Measuring Temperature	• Body temperature varies during the day. It is lower in the morning and higher in the evening. It may vary somewhat based on the method used to take the temperature, the person's condition, and the time of day. • Measure temperature the same way every time. • Read the thermometer and write the numbers down on paper. • Clean the thermometer with soap and water, or alcohol. • When reporting temperature measurements to a health care provider, be sure to say which method was used.	If the temperature is very high or low, or if you have any concerns, contact your health care provider. Ensures accuracy and provides accurate information.
Using a Thermometer in the Mouth	• Wait 20 to 30 minutes after drinking or eating to measure oral temperature. • Turn the thermometer on. • Put the thermometer in the mouth and under the tongue in the back. Close the lips around the thermometer. Do not bite down with the teeth. • Listen for the signal or beep. • Remove the thermometer.	Consuming hot or cold foods can affect the reading.
Using a Tympanic Membrane Thermometer	• Turn the thermometer on. • Insert the ear probe snugly into the ear canal using gentle but firm pressure, angling toward the jaw. If the person is younger than 3 years, pull the ear lobe back and down. • Push the button to take the temperature and hold until reading is obtained. • Remove the thermometer.	Using equipment properly ensures accurate measurements.
Using a Temporal Artery Thermometer	• Turn the thermometer on. • Place it firmly against the center of the forehead. • Push the "on" button. Keep the button depressed while taking the	

	temperature. • Slowly slide the thermometer straight across the forehead to the hairline. • Lift the thermometer from the forehead and touch it to the neck just behind the ear lobe. • Release the button.	
Using a Thermometer Under the Arm	• Turn the thermometer on. • Put the thermometer under the arm. • Fold the arm down and across the chest to hold it in place. • Listen for the signal or beep. • Remove the thermometer.	
Measuring the Pulse	• The pulse is often taken before taking certain medications, such as those to make the heartbeat slower or stronger. People who exercise and want to monitor the effect of the exercise on heart function may also take their pulse. • It is necessary to be able to see a watch or a clock with a second hand when taking the pulse. • Place one arm on a firm surface so that the palm is upward. Using the middle three fingers of the other hand, gently feel the outside of the arm just below the wrist with the fingertips. Do not press hard. When pulsations are felt, observe the second hand of the watch or clock and begin to count when the second hand reaches 12 (any number is fine, but it is often easier to remember to always begin counting when the second hand is on 12). Count each pulsation (beat) for 1 minute (when the second hand again reaches 12), and write the number down.	If the pulse is very fast, very slow, or irregular, or if you have any concerns, contact your health care provider.
Measuring Blood Pressure	• The blood pressure is often taken to determine how well medications are working to control high blood pressure. The blood pressure is usually checked once a week, or as instructed. Readings may be taken in the morning and evening. A record of blood pressure readings over time is more important than one reading. • Use a validated monitor with an automatic inflation cuff. • Avoid food, caffeine, tobacco, and alcohol for 30 minutes before taking a measurement. • Take your blood pressure before (not after) you eat. • Rest 3 to 5 minutes before taking your blood pressure. • Sit comfortably with your back supported and both feet on the floor (don’t cross your legs).	Home blood pressure monitoring is the ideal method for monitoring the response to treatment for high blood pressure. If the blood pressure numbers increase or decrease by more than 10, or if you have any concerns, contact your health care provider. Ensures accuracy of readings.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Elevate your arm to heart level on a table or a desk.
- Use the proper-sized cuff. It should fit smoothly and snugly around your bare upper arm. There should be enough room to slip a fingertip under the cuff. The bottom edge of the cuff should be 1 inch above the crease of the elbow.
- Follow instructions that come with the home device.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the goal of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop expertise in assessing patients' vital signs, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following while assessing vital signs and providing nursing care:

- Did your preparation and practice related to the measurement and assessment of vital signs result in your feeling confident in your ability to gather reliable, accurate data? Did your competence and confidence inspire the patient's and family/caregiver's trust?

How did you prioritize the data you collected? What patterns in the data did you identify?

What knowledge from your learning, personal experience and intuition did you use to make decisions and develop your plan of care?

- How confident are you that the data you communicated and recorded accurately communicates the health status of the patient? How successfully have you communicated this information to other members of the health care team?
- Were you aware of any cultural and/or ethnic beliefs or practices that may have influenced the health practices and beliefs of patients and/or family members/caregivers related to vital signs? Were you aware of any stereotypes or prejudices that might have negatively influenced the clinical encounter? If so, how did you address these?
- Was the patient/family/caregiver participation in the process at an optimal level? How might you have better engaged the patient and family/caregivers? Did the patient sense that you are respectful, caring, and competent to obtain accurate and relevant data?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of assessing their health status through assessment of vital signs? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

Skill 26-1

Assessing Body Temperature

Skill Variation: ***Assessing Body Temperature Using a Noncontact Infrared Thermometer***

DELEGATION CONSIDERATIONS

Measurement of body temperature may be delegated to assistive personnel (AP) as well as to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Digital or electronic thermometer, appropriate for site to be used
- Disposable probe covers
- Water-soluble lubricant for rectal temperature measurement
- Nonsterile gloves, if appropriate
- Additional personal protective equipment (PPE), as indicated
- Toilet tissue, if needed
- Electronic record or pen and paper or flow sheet

IMPLEMENTATION

ACTION	RATIONALE
1. Check the prescribed interventions or plan of care for frequency of measurement and route. More frequent temperature measurement may be appropriate based on nursing judgment.	Assessment and measurement of vital signs at appropriate intervals provide important data about the patient's health status.
 2. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 3. Identify the patient.	Identifying the patient ensures that the right patient receives the intervention and helps prevent errors.
4. Close the curtains around the bed and close the door to the room, if possible. Discuss the procedure with the patient and assess the patient's ability to assist with the procedure.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates cooperation. Dialogue encourages patient participation and allows for individualized nursing care.
5. Assemble equipment on the overbed table within reach.	Organization facilitates performance of task.
6. Ensure that the electronic or digital thermometer is in working condition.	Improperly functioning thermometer may not give an accurate reading.
7. Put on gloves, if indicated.	Gloves prevent contact with blood and body fluids. Gloves are usually not required for an oral, axillary, or tympanic temperature measurement, unless contact with blood or body fluids is anticipated. Gloves should be worn for rectal temperature measurement.
8. Select the appropriate site based on assessment data.	This ensures safety and accuracy of measurement.
9. Follow the steps as outlined below for the	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

appropriate type of thermometer.

10. When measurement is completed, remove gloves, if worn. Remove additional PPE, if used. Perform hand hygiene.

Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms.

Measuring an Oral Temperature

11. Remove the electronic unit from the charging unit and remove the probe from within the recording unit.

Electronic unit must be taken into the patient's room to assess the patient's temperature. On some models, the machine is turned on when the probe is removed.

12. Cover thermometer probe with disposable probe cover, sliding it on until it snaps into place (Figure 1).

Using a cover prevents contamination of the thermometer probe.

13. **Place the probe beneath the patient's tongue in the posterior sublingual pocket (Figure 2). Ask the patient to close their lips around the probe.**

When the probe rests deep in the posterior sublingual pocket, it is in contact with blood vessels lying close to the surface.

14. Continue to hold the probe until you hear a beep (Figure 3). Note the temperature reading.

If left unsupported, the weight of the probe tends to pull it away from the correct location. The probe must remain in the sublingual pocket for the full period of measurement to ensure accurate measurement. The signal indicates that the measurement is completed. The electronic thermometer provides a digital display of the measured temperature.

15. Remove the probe from the patient's mouth. Dispose of the probe cover by holding the probe over an appropriate receptacle and pressing the probe-release button (Figure 4).

Disposing of the probe cover ensures that it will not be reused accidentally on another patient. Proper disposal prevents spread of microorganisms.

16. Return the thermometer probe to the storage place within the unit. Return the electronic unit to the charging unit, if appropriate.

The thermometer needs to be recharged for future use. If necessary, the thermometer should stay on the charger so that it is ready to use at all times.

FIGURE 1. Putting probe cover on the thermometer.

FIGURE 2. Placing thermometer under the tongue in the posterior sublingual pocket.

FIGURE 3. Holding probe in the patient's mouth.

FIGURE 4. Pushing button to dispose of cover.

Measuring a Tympanic Membrane Temperature

17. If necessary, push the "ON" button and wait for the "ready" signal on the unit.	For proper function, the thermometer must be turned on and warmed up.
18. Attach the disposable cover onto the tympanic probe (Figure 5).	Use of a disposable cover deters the spread of microorganisms.
19. **Insert the probe snugly into the external ear using gentle but firm pressure, angling the thermometer toward the patient's jaw line. Pull the pinna up and back to straighten the ear canal in an adult (Figure 6).**	If the probe is not inserted correctly, the patient's temperature may be noted as lower than normal.

FIGURE 5. Attaching the disposable cover onto the tympanic probe.

FIGURE 6. Thermometer in patient's ear canal with pinna pulled up and back.

20. Activate the unit by pushing the trigger button. The reading is immediate (usually within 2 seconds). Note the reading.	The digital thermometer must be activated to record the temperature.
21. Discard the probe cover in an appropriate receptacle by pushing the probe-release button or use the rim of cover to remove it from the probe (Figure 7). Replace the thermometer in its charger, if necessary.	Discarding the probe cover ensures that it will not be reused accidentally on another patient. Proper disposal prevents the spread of microorganisms. If necessary, the thermometer should stay on the charger so that it is ready to use at all times.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 7. Disposing of probe cover.

Measuring Temporal Artery Temperature

If the temporal artery and behind the ear locations are not accessible, the femoral artery, lateral thoracic artery, and axillary sites may be used to assess body temperature using a temporal artery thermometer (Exergen, n.d.b).

22. Brush the patient's hair aside if it is covering the temporal artery area.

Anything covering the area—such as a hat, hair, wigs, or bandages—would insulate the area, resulting in falsely high readings. Measure only the side of the head exposed to the environment.

23. Apply a probe cover.

Using a cover prevents contamination of the thermometer probe.

24. Hold the thermometer like a remote-control device, with your thumb on the red "ON" button. Place the probe flush on the center of the forehead, with the body of the instrument sideways (not straight up and down) so that it is not in the patient's face (Figure 8).

Allows for easy use of the device and reading of the display. Holding the instrument straight up and down could be intimidating for the patient, particularly young patients and/or those with alterations in mental status.

25. Depress the "ON" button. Keep the button depressed throughout the measurement.

26. **Slowly slide the probe straight across the forehead, midline, to the hairline, maintaining contact with the skin (Figure 9). Do not move the probe down the side of the face.**

Midline on the forehead, the temporal artery is less than 2 mm below the skin, whereas at the side of the face, the temporal artery is much deeper. Measuring there would result in falsely low readings. Slow movement and continuous contact with the skin are necessary to ensure accurate results.

FIGURE 8. Placing the thermometer probe on the center of the forehead.

FIGURE 9. Sliding the probe across the forehead to the hairline.

27. If required, based on specific thermometer in use, brush hair aside if it is covering the ear, exposing the area of the neck under the ear lobe. Keeping the button depressed, lift the probe from the forehead

Sweat causes evaporative cooling of the skin on the forehead, possibly leading to a falsely low reading. During diaphoresis, the area on the head behind the ear lobe exhibits high blood flow necessary for the

and touch on the neck just behind the ear lobe, in the depression just below the mastoid (Figure 10).	arterial measurement; it is a double check for the thermometer (Exergen, n.d.a).

FIGURE 10. Touching the probe behind the ear.

28. Release the button and read the thermometer measurement.	
29. Hold the thermometer over a waste receptacle. Gently push the probe cover with your thumb against the proximal edge to dispose of the probe cover.	Discarding the probe cover ensures that it will not be reused accidentally on another patient.
30. The instrument will automatically turn off in 30 seconds, or press and release the power button.	Turns thermometer off.

Measuring Axillary Temperature

31. Remove the probe from the recording unit of the electronic thermometer. Place a disposable probe cover on by sliding it on and snapping it securely.	Using a cover prevents contamination of the thermometer probe.
32. Move the patient's clothing to expose only the axilla (Figure 11).	The axilla must be exposed for placement of the thermometer. Exposing only the axilla keeps the patient warm and maintains their dignity.
33. **Place the end of the probe in the center of the axilla (Figure 12). Have the patient bring the arm down and close to the body.** Hold the patient's arm by the patient's side until the measurement is complete.	The deepest area of the axilla provides the most accurate measurement; surrounding the bulb with skin surface provides a more reliable measurement.

FIGURE 11. Exposing axilla to assess temperature.

FIGURE 12. Placing thermometer in the center of the axilla.

34. Hold the probe in place until you hear a beep, and then carefully remove the probe. Note the temperature reading.	Axillary thermometers must be held in place to obtain an accurate temperature.
35. Cover the patient and help them to a position of comfort.	This ensures patient comfort.
36. Dispose of the probe cover by holding the probe over	Discarding the probe cover ensures that it will not be

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

an appropriate waste receptacle and pushing the release button.	reused accidentally on another patient.
37. Place the bed in the lowest position and elevate rails, as needed. Leave the patient clean and comfortable.	Low bed position and elevated side rails provide for patient safety.
38. Return the electronic thermometer to the charging unit.	The thermometer needs to be recharged for future use.

Measuring Rectal Temperature

39. Adjust the bed to a comfortable working height (VHACEOSH, 2016). Put on nonsterile gloves.	Having the bed at the proper height prevents back and muscle strain. Gloves prevent contact with contaminants and body fluids.
40. Assist the patient to a side-lying position. Pull back the covers sufficiently to expose only the buttocks. Position a young infant supine with legs flexed (Kyle & Carmen, 2021).	The side-lying position allows the nurse to see the buttocks. Exposing only the buttocks keeps the patient warm and maintains their dignity. Rectal temperatures are not normally taken in newborns, infants, and young children (Jensen, 2019; Silbert-Flagg & Pillitteri, 2018), but may be indicated. Refer to the Special Considerations section at the end of the skill.
41. Remove the rectal probe from within the recording unit of the electronic thermometer. Cover the probe with a disposable probe cover, sliding it on until it snaps in place (Figure 13).	Using a cover prevents contamination of the thermometer.

FIGURE 13. Removing appropriate probe and attaching disposable probe cover.

42. **Lubricate about 1 inch of the probe with a water-soluble lubricant (Figure 14).**	Lubrication reduces friction and facilitates insertion, minimizing the risk of irritation or injury to the rectal mucous membranes.
43. Reassure the patient. Separate the buttocks until the anal sphincter is clearly visible.	If not placed directly into the anal opening, the thermometer probe may injure adjacent tissue or cause discomfort.
44. **Insert the thermometer probe into the anus about 1.5 inches in an adult or no more than 1 inch in children (Figure 15)** (Kyle & Carmen, 2021).	Depth of insertion must be adjusted based on the patient's age. Rectal temperatures are not normally taken in newborns, infants, and young children (Jensen, 2019; Silbert-Flagg & Pillitteri, 2018), but may be indicated. Refer to the Special Considerations section at the end of the skill.

FIGURE 14. Lubricating thermometer tip.

FIGURE 15. Inserting thermometer into the anus.

45. Hold the probe in place until you hear a beep, then carefully remove the probe. Note the temperature reading on the display.	If left unsupported, movement of the probe in the rectum could cause injury and/or discomfort. The signal indicates that the measurement is completed. The electronic thermometer provides a digital display of the measured temperature.
46. Dispose of the probe cover by holding the probe over an appropriate waste receptacle and pressing the release button.	Proper probe cover disposal reduces risk of microorganism transmission.
47. Using toilet tissue, wipe the anus of any feces or excess lubricant. Dispose of the toilet tissue. Remove gloves and discard them. Perform hand hygiene.	Wiping promotes cleanliness. Disposing of the toilet tissue avoids transmission of microorganisms.
48. Cover the patient and help them to a position of comfort.	This ensures patient comfort.
49. Place the bed in the lowest position; elevate rails as needed.	These actions provide for the patient's safety.
50. Perform hand hygiene.	Hand hygiene prevents the spread of microorganisms.
51. Return the thermometer to the charging unit.	The thermometer needs to be recharged for future use.

DOCUMENTATION

Guidelines

Record temperature in the electronic record or flow sheet. Communicate abnormal findings to the appropriate person. Identify the site of assessment used if other than oral.

Sample Documentation

Practice documenting body temperature and other vital signs in *Lippincott DocuCare*.

10/20/25 Tympanic temperature assessed. Temperature 102.5°F. Patient states she has "a pounding" headache; denies chills, malaise. Physician notified. Received order to give 650 mg PO acetaminophen now. Incentive spirometer × 10 q 2 hours.

—M. Evans, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *Temperature reading is higher or lower than expected based on your assessment:* Reassess temperature with a different thermometer. The thermometer may not be calibrated correctly. If using a tympanic thermometer, improper positioning of the probe can contribute to errors (Jensen, 2019).
- *During rectal temperature assessment, the patient reports feeling light-headed or passes out:* Remove the thermometer immediately. Quickly assess the patient's blood pressure and heart rate. Vagal stimulation during insertion of the probe may cause reduction in the patient's heart rate (Jensen, 2019). Notify the health care provider. Do not attempt to take another rectal temperature on this patient.

SPECIAL CONSIDERATIONS

General Considerations

- Glass thermometers with mercury-filled bulbs are not used in health care institutions to measure body temperature due to federal safety recommendations (U.S. Environmental Protection Agency [EPA], n.d.).
- If the patient smoked, chewed gum, or consumed hot or cold food or fluids recently, wait 15 minutes before taking an oral temperature to allow the oral tissues to return to baseline temperature (Mayo Clinic, 2020a).
- Nasal oxygen is not thought to affect oral temperature readings. Do not assess oral temperatures in patients receiving oxygen by mask. Removal of the mask for the time period required for assessment could result in a serious drop in the patient's blood oxygen level.
- When using a tympanic thermometer, make sure to insert the probe into the ear canal sufficiently tightly to seal the opening to ensure an accurate reading.
- A dirty probe lens and cone on the temporal artery thermometer can cause a falsely low reading. If the lens is not shiny in appearance, clean the lens with an alcohol swab or gauze moistened in alcohol (Exergen, n.d.b).
- If the temporal artery and behind the ear locations are not accessible, the femoral artery, lateral thoracic artery, and axilla sites may be used to assess body temperature using a temporal artery thermometer (Exergen, n.d.b).
- If the patient's axilla has been washed recently, wait 15 to 30 minutes before taking an axillary temperature to allow the skin to return to baseline temperature.

Infant and Child Considerations

- Pull the pinna back and down when measuring tympanic temperature on a child younger than 3 years of age. For children older than 3 years of age, there is no need to manipulate the pinna (Kyle & Carman, 2021).
- Small children have a limited attention span and difficulty keeping their lips closed long enough to obtain an accurate oral temperature reading. Based on an assessment of the child's ability to cooperate, it may be more appropriate to use the temporal or tympanic site.
- For children under 3 months (90 days) old, the axillary method is safest and is good for screening (Seattle Children's, 2022). If the axillary temperature is above 99 F, recheck with a rectal measurement. The rectal or temporal method should be used for children 3 months to 4 years old; the tympanic method can be used after 6 months of age (Seattle Children's, 2022). In children age 4 years or older, it is safe to measure temperature orally, in addition to tympanic and axillary methods (Seattle Children's, 2022).

Community-Based Care Considerations

- Teach patients who use electronic or digital thermometers to clean the probe after use to prevent transmission of microorganisms among family members/caregivers. Clean according to the manufacturer's directions.
- Patients may still be using glass mercury thermometers at home. Encourage patients to use alternative devices, such as digital thermometers.
- Teach patients using nonmercury glass thermometers to clean the thermometer after use in lukewarm soapy water and rinse in cool water. Store it in an appropriate place to prevent breakage and injury from the glass. Encourage patients to use alternative devices, such as digital thermometers.
- Teach patients that glass thermometers should never be used to take a temperature for a person who is unconscious or for infants and young children.
- Pacifier thermometers are not recommended for use (Mayo Clinic, 2020).

Skill Variation

Assessing Body Temperature Using a Noncontact Infrared Thermometer

Noncontact infrared (IFR) thermometers measure body temperature by capturing the heat emitted by the skin over body surfaces at various locations. Comparisons of noncontact IFR thermometer measurements with

tympanic, temporal artery, and axillary body temperature measurement have resulted in inconsistent findings related to accuracy of measurements (Aw, 2020; Berksoy et al., 2018; Franconi et al., 2018; Wang et al., 2013). As a result, this method of temperature measurement has been suggested for possible use as screening for fever, not for ongoing monitoring of body temperature (Aw, 2020; Bayhan et al., 2014; Berksoy et al., 2018; Canadian Agency for Drugs and Technologies in Health, 2014). Locations recommended for use for measurement include over the forehead (temporal artery), the neck (carotid artery), umbilicus, axilla, and nape of the neck (Berksoy et al., 2018; U.S. FDA, 2020a; Wang et al., 2013). **Proper use of the noncontact thermometer is essential to achieve as accurate measurement as possible and prevent inaccurate measurement** (U.S. FDA, 2020a).

1. Ensure the noncontact IFR thermometer has been exposed to the testing environment or room for 10 to 30 minutes prior to use to allow the thermometer to adjust to the environment.
2. Refer to Steps 1–8 in Skill 26-1.
3. Follow specific manufacturer instructions for use.
4. Use in a draft-free space that is out of direct sun and away from radiant heat sources (U.S. FDA, 2020a).
5. The patient's forehead should not be blocked or covered during measurement.
6. Clean and dry the patient's forehead.
7. Power the thermometer on.
8. Change mode setting, if necessary, based on thermometer features, to "Body."

FIGURE A. Holding the device perpendicular from the patient's forehead. (*Source:* Used with permission from iStock. *Photo by ozgurdonmaz*.)

9. Hold the device perpendicular and 1 to 2 inches from the patient's forehead, or the distance recommended by the manufacturer (Figure A).
10. Press the "Scan" button. Measurement is almost instantaneous; note temperature measurement.
11. If a repeat measurement is necessary, follow the manufacturer's directions for the appropriate time interval between readings.

12. When measurement is completed, remove gloves, if worn. Remove additional PPE, if used. Perform hand hygiene.

Skill 26-2 Assessing a Peripheral Pulse by Palpation

DELEGATION CONSIDERATIONS

The measurement of the radial and brachial peripheral pulses may be delegated to assistive personnel (AP). The measurement of peripheral pulses may be delegated to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Watch with second hand or digital readout
- Electronic record or pen and paper or flow sheet
- Nonsterile gloves, if appropriate; additional PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE
1. Check prescribed interventions or plan of care for frequency of pulse assessment. More frequent pulse measurement may be appropriate based on nursing judgment.	Assessment and measurement of vital signs at appropriate intervals provide important data about the patient's health status.
 2. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 3. Identify the patient.	Identifying the patient ensures the right patient receives the intervention and helps prevent errors.
4. Close the curtains around the bed and close the door to the room, if possible. Discuss the procedure with the patient and assess the patient's ability to assist with the procedure.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates cooperation.
5. Put on gloves, if indicated.	Gloves are not usually worn to obtain a pulse measurement unless contact with blood or body fluids is anticipated. Gloves prevent contact with blood and body fluids.
6. Select the appropriate peripheral site based on assessment data.	This ensures safety and accuracy of measurement.
7. Move the patient's clothing to expose only the site chosen.	The site must be exposed for pulse assessment. Exposing only the site keeps the patient warm and maintains their dignity.
8. Place your first, second, and third fingers over the artery (Figure 1). Place your fingers over the artery so that the ends of your fingers are flat against the patient's skin when palpating peripheral pulses. Do not press with the tip of the fingers only. **Lightly compress the artery so pulsations can be felt and counted.**	The sensitive fingertips can feel the pulsation of the artery.

FIGURE 1. Placing fingers over the artery.

9. Using a watch with a second hand, count the number of pulsations felt for 30 seconds (Figure 2). Multiply this number by 2 to calculate the rate for 1 minute. **If the rate, rhythm, or amplitude of the pulse is abnormal in any way, palpate and count the pulse for 1 minute.**	Ensures accuracy of measurement and assessment.

FIGURE 2. Counting the pulse.

10. Note the rhythm and amplitude of the pulse, as well as the elasticity of the blood vessel.	This provides additional assessment data regarding the patient's cardiovascular status.
11. When measurement is completed, remove gloves, if worn. Perform hand hygiene. Cover the patient and help them to a position of comfort.	Proper removal of gloves reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms. Covering and positioning the patient ensures patient comfort.
12. Remove additional PPE, if used. Perform hand hygiene.	Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms.

DOCUMENTATION

Guidelines

Record pulse rate, strength, rhythm and elasticity in the electronic record or flow sheet. Identify site of assessment. Communicate abnormal findings to the primary care provider.

Sample Documentation

Practice documenting pulse and other vital signs in *Lippincott DocuCare*.

2/6/125 1000 Pulses 84, regular, 2+, normal elasticity; equal bilaterally in radial, popliteal, and dorsalis pedis sites.

—M. Evans, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *The pulse is irregular:* Monitor the pulse for a full minute. If the pulse is difficult to assess, validate pulse measurement by taking the apical pulse for 1 minute. If this is a change for the patient, notify the primary care provider.
- *The pulse is palpated easily, but then disappears:* Apply only moderate pressure to the pulse. Applying too much pressure may obliterate the pulse.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- *You cannot palpate a pulse:* Use a portable Doppler ultrasound to assess the pulse. If this is a change in assessment or if you cannot find the pulse using a Doppler ultrasound, notify the primary care provider. If you can find the pulse using a Doppler ultrasound, place a small X over the spot where the pulse is located, based on facility policy. This can make palpating the pulse easier because the exact location of the pulse is known.

SPECIAL CONSIDERATIONS

General Considerations

- The normal heart rate varies by age.
- The carotid pulse should be palpated only in the lower third of the neck to avoid stimulation of the carotid sinus (Jensen, 2019, p. 95). When palpating a carotid pulse, lightly press only one side of the neck at a time. Never attempt to palpate both carotid arteries at the same time. Bilateral palpation could result in reduced cerebral blood flow and cause the patient to lose consciousness (Jensen, 2019).
- If a peripheral pulse is difficult to assess accurately because it is irregular, feeble, or extremely rapid, assess the apical rate.

Infant and Child Considerations

- In children younger than 2 years of age, auscultate an apical pulse rate (refer to the Guidelines for Nursing Care 26-3 on page 731) (Jarvis & Eckhardt, 2020; Kyle & Carmen, 2021).
- In children older than age 2 years, use the radial site for pulse assessment and count for 1 minute (Jarvis & Eckhardt, 2020; Kyle & Carmen, 2021).
- Measure the apical rate if the child has a cardiac problem or congenital heart defect (see Guidelines for Nursing Care 26-3 on page 731).

Community-Based Care Considerations

- Teach the patient and family members/caregivers how to take the patient's pulse, if appropriate.
- Inform the patient and family/caregivers about digital pulse monitoring devices.
- Teach family members/caregivers how to locate and monitor peripheral pulse sites, if appropriate.

Skill 26-3 Assessing Respiration

DELEGATION CONSIDERATIONS

The measurement of respirations may be delegated to assistive personnel (AP) as well as to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Watch with second hand or digital readout
- Electronic record or pen and paper or flow sheet
- PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE
1. **While your fingers are still in place for the pulse measurement, after counting the pulse rate, observe the patient's respirations (Figure 1).**	The patient may alter the rate of respirations if they are aware they are being counted (Hill et al., 2018).

FIGURE 1. Assessing respirations.

2. Note the rise and fall of the patient's chest.	A complete cycle of an inspiration and an expiration composes one respiration.
3. Using a watch with a second hand, count the number of respirations for 30 seconds. Multiply this number by 2 to calculate the respiratory rate per minute. **Avoid counting for a 15-second interval.**	Sufficient time is necessary to observe the rate, depth, and other characteristics (Hill et al., 2018; Jarvis & Eckhardt, 2020). Use of a 15-second interval and multiplying by 4 can result in a respiratory count that is significantly incorrect (Hill et al., 2018; Jarvis & Eckhardt, 2020). Some literature suggests 60-second counts should be implemented whenever possible to ensure accuracy (Kallioinen et al., 2017).
4. **If respirations are abnormal in any way, count the respirations for at least 1 full minute** (Jarvis & Eckhardt, 2020).	Increased time allows the detection of unequal timing between respirations.
5. Note the depth and rhythm of the respirations.	This provides additional assessment data regarding the patient's respiratory status (Jarvis & Eckhardt, 2020).
6. When measurement is completed, remove gloves, if worn. Perform hand hygiene. Cover the patient and help them to a position of comfort.	Proper removal of gloves reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms. Covering and positioning the patient ensures patient comfort.
7. Remove additional PPE, if used. Perform hand hygiene.	Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene deters the spread of microorganisms.

DOCUMENTATION

Guidelines

Document respiratory rate, depth, and rhythm on electronic record or flow sheet. Communicate any abnormal findings to the appropriate person.

Sample Documentation

Practice documenting respiration and other vital signs in *Lippincott DocuCare*.

10/23/25 0830 Patient breathing at a rate of 16 respirations per minute. Respirations regular and unlabored.

—M. Evans, RN

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *The patient is breathing with such shallow respirations that you cannot count the rate:* Sometimes it is easier to count respirations by auscultating the lung sounds. Auscultate lung sounds and count respirations for 30 seconds. Multiply by 2 to calculate the respiratory rate per minute. If the respiratory rate is irregular, count for a full minute. Notify the primary health care provider of the respiratory rate and the shallowness and irregularity of the respirations.

SPECIAL CONSIDERATIONS

- If respiratory rate or depth is irregular, count respirations for 1 minute.
- If respirations are very shallow and difficult to detect, observe the sternal notch, where respiration is more apparent.
- If respirations are difficult to detect, such as with patients who are obese or with children, place a hand on the upper chest or abdomen to feel the respiratory rate (Jarvis & Eckhardt, 2020). Alternatively, place a hand on the patient's shoulder to feel the respiratory rate (Jensen, 2019).

General Considerations

- If respiratory rate or depth is irregular, count respirations for 1 minute.
- If respirations are very shallow and difficult to detect, observe the sternal notch, where respiration is more apparent.
- If respirations are difficult to detect, such as with patients who are obese or with children, place a hand on the upper chest or abdomen to feel the respiratory rate (Jarvis & Eckhardt, 2020). Alternatively, place a hand on the patient's shoulder to feel the respiratory rate (Jensen, 2019).

Infant and Child Considerations

- For infants and children, count respirations for 1 full minute to ensure accuracy (Kyle & Carmen, 2021).
- Infants' respirations are primarily diaphragmatic; count abdominal movements to assess respiratory rate for infants (Jensen, 2019; Kyle & Carmen, 2021).
- Count thoracic movements to assess respiratory rate for infants and children older than 1 year of age (Kyle & Carmen, 2021).
- Assess respirations before taking the temperature so that the child is not crying, which would alter the respiratory status.
- Assess respirations in infants and children when the child is resting or sitting quietly, because respiratory rate often changes when infants or young children cry, feed, or become more active. The most accurate respiratory rate is obtained when the infant or child is at rest (Jensen, 2019; Kyle & Carmen, 2021).

Skill 26-4 Assessing Blood Pressure Using an Automated, Electronic Oscillometric Device

DELEGATION CONSIDERATIONS

The measurement of brachial artery blood pressure may be delegated to assistive personnel (AP) as well as to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Blood pressure cuff of appropriate size
- Automated, electronic oscillometric blood pressure device
- Electronic record or pen and paper or flow sheet
- PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE

1. Check the prescribed interventions or plan of care for frequency of blood pressure measurement. More frequent measurement may be appropriate based on nursing judgment.	Provides for patient safety.
 2. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 3. Identify the patient.	Identifying the patient ensures the right patient receives the intervention and helps prevent errors.
4. Close the curtains around the bed and close the door to the room, if possible. Discuss the procedure with the patient and assess patient's ability to assist with the procedure. Validate that the patient has relaxed for several minutes.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates cooperation. Activity immediately before measurement can result in inaccurate results.
5. Put on gloves, if indicated.	Gloves prevent contact with blood and body fluids. Gloves are usually not required for measurement of blood pressure, unless contact with blood or body fluids is anticipated.
6. Select the appropriate arm (or alternate site) for measurement and blood pressure cuff (refer to Table 26-8 on page 738).	Decision on measurement site and cuff size is based on nurse's assessment of individual patient circumstances. Incorrect cuff size contributes to the most frequent error in measurement in nonacute care settings (Muntner et al., 2019).
7. Have the patient assume a comfortable lying or sitting position with the forearm supported at the level of the heart and the palm of the hand upward (Figure 1). If the measurement is taken in the supine position, support the arm with a pillow. In the sitting position, support the arm yourself or by using the bedside table. If the patient is sitting, have the patient sit back in the chair so that the chair supports their back. In addition, make sure the patient keeps the legs uncrossed.	The position of the arm can have a major influence when the blood pressure is measured; if the upper arm is below the level of the right atrium, the readings will be too high. If the arm is above the level of the heart, the readings will be too low (Muntner et al., 2019; Pickering et al., 2005). This position places the brachial artery on the inner aspect of the elbow so that the bell or diaphragm of the stethoscope can rest on it easily. Support for the patient's arm prevents isometric exercise that will affect the blood pressure level (Muntner et al., 2019). If the back is not supported, the diastolic pressure may be elevated falsely; if the legs are crossed, the systolic pressure may be elevated falsely (Muntner et al., 2019; Pickering et al., 2005).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 1. Proper positioning for blood pressure assessment using brachial artery.

8. Expose the brachial artery by removing garments or move a sleeve if it is not too tight, above the area where the cuff will be placed.	Clothing over the artery interferes with the ability to hear sounds and can cause inaccurate blood pressure readings. A tight sleeve would cause congestion of blood and possibly inaccurate readings (Muntner et al., 2019).
9. Palpate the location of the brachial artery. Center the bladder of the cuff over the brachial artery, about midway on the upper arm, so that the lower edge of the cuff is about 2.5 to 5 cm (1 to 2 inches) above the inner aspect of the elbow (Figure 2). **Line up the artery marking on the cuff with the patient's brachial artery.** The tubing should extend from the edge of the cuff nearer the patient's elbow (Figure 3).	Pressure in the cuff applied directly to the artery provides the most accurate readings. If the cuff gets in the way of the stethoscope, readings are likely to be inaccurate. A cuff placed upside down with the tubing toward the patient's head may give a false reading.
10. Wrap the cuff around the arm smoothly and snugly, and fasten it (Figure 4). Do not allow any clothing to interfere with the proper placement of the cuff.	A smooth cuff and snug wrapping produce equal pressure and help promote an accurate measurement. A cuff wrapped too loosely results in an inaccurate reading.
11. Turn on the machine. **If the machine has different settings for infants, children, and adults, select the appropriate setting.** Push the start button. Instruct the patient to hold the limb still and refrain from speaking.	Keeping the limb still and refraining from talking provide for accurate measurement of blood pressure levels (Muntner et al., 2019).
12. Wait until the machine beeps and the blood pressure reading appears. Note the reading (Figure 5).	Beep signals completion of reading.

FIGURE 2. Centering the bladder of the cuff over the brachial artery.

FIGURE 3. Cuff tubing extending from the edge of the cuff nearer the patient's elbow.

FIGURE 4. Wrapping the cuff around the arm smoothly and snugly.

FIGURE 5. Noting the blood pressure reading.

13. Remove the cuff from the patient's limb and clean and store the equipment.	Cleaning of equipment prevents transmission of microorganisms and prepares equipment for future

use.

14. Remove gloves, if worn. Perform hand hygiene. Cover the patient and help them to a position of comfort.

Removing gloves properly reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms. Covering and positioning the patient ensures patient comfort.

15. Remove additional PPE, if used. Perform hand hygiene.

Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene deters the spread of microorganisms.

DOCUMENTATION

Guidelines

Record the findings on the electronic record or flow sheet. Communicate abnormal findings to the primary health care provider. Identify arm used or site of assessment if other than brachial.

Sample Documentation

Practice documenting blood pressure and other vital signs in *Lippincott DocuCare*.

10/18/25 0945 Blood pressure taken in right arm 180/88. Dr. Brown notified. Patient denies dizziness, headache. Captopril 25 mg PO twice a day prescribed. Blood pressure to be repeated 30 minutes after administering medication.

—M. Evans, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

SPECIAL CONSIDERATIONS

General Considerations

- It is recommended that blood pressure measurements should be checked in both arms at the first examination (Muntner et al., 2019; Pickering et al., 2005). Most people have differences in blood pressure readings between arms. When there is a consistent interarm difference, use the arm with the higher pressure (Muntner et al., 2019; Pickering et al., 2005).
- Separate repeated blood pressure measurements in the same arm by 1 to 2 minutes to avoid inaccurate results (Muntner et al., 2019).
- Blood pressure can be assessed by auscultation with a sphygmomanometer and stethoscope (see Skill 26-5); systolic blood pressure can be assessed using Doppler ultrasound (refer to the Guidelines for Nursing Care 26-6 on page 742).
- Incorrect cuff size contributes to the most frequent error in measurement in nonacute care settings (Muntner et al., 2019). *If the cuff is too narrow*, the reading could be erroneously high because the pressure is not evenly transmitted to the artery. *If a cuff is too wide,* the reading may be erroneously low because pressure is dispersed over a disproportionately large surface area.
- Diastolic blood pressure measured while the patient is supine is approximately 1 to 5 mm Hg higher than when measured while the patient is sitting; systolic blood pressure measured while the patient is supine is approximately 3 to 10 mm Hg higher than when measured while the patient is sitting (Muntner et al., 2019).
- Automated electronic oscillometric wrist monitors have been developed that measure blood pressure in the forearm using the radial artery. Forearm measurements tend to be higher than the upper arm measurements (Halm, 2014). The accuracy of readings with forearm monitors is affected by the position of the wrist relative to the heart. This can be avoided if the wrist is always at heart level when the reading is taken (Pickering et al., 2005).
- The wrist site for measurement has been suggested as an alternative for obtaining blood pressure readings in people who are obese. It is often difficult to obtain the appropriately sized cuff for the upper arm, given arm circumference and conical-shaped upper arms common in obesity. The conical shape of the upper arm makes it difficult to fit the cuff to the arm, increasing the likelihood of inaccurate blood pressure measurement (Halm, 2014). Thus, measurement in the forearm can be a possible solution to this problem (Muntner et al., 2019; Palatini, 2018).
- When the patient's brachial artery is inaccessible and/or the use of the upper arm is contraindicated, you can assess

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the blood pressure using the popliteal artery in the leg. The systolic blood pressure is at least 15 to 20 mm Hg higher at this site than the arm, although the diastolic pressure is the same (Muntner et al., 2019; Sheppard et al., 2019).

Infant and Child Considerations

- Use oscillometric devices that have been validated for use with children and adolescents (Muntner et al., 2019).
- In children, if elevated blood pressure is present when measure with an oscillometric device, auscultation should be performed to define blood pressure levels (Muntner et al., 2019).
- The use of wrist monitors is not recommended for pediatric patients (Muntner et al., 2019).
- Blood pressure should be taken in the right arm for children to align with normative data (Muntner et al., 2019).
- In infants and small children, the lower extremities are commonly used for blood pressure monitoring at the popliteal, dorsalis pedis, and posterior tibial sites. In children older than 1 year of age, the systolic pressure in the thigh tends to be 10 to 40 mm Hg higher than in the arm; the diastolic pressure remains the same (Kyle & Carman, 2021).
- Infants and children presenting with cardiac complaints may have blood pressures assessed in all four extremities. Large differences among blood pressure readings between the upper and lower extremities can indicate heart defects, such as coarctation of the aorta (Kyle & Carman, 2021).

Community-Based Care Considerations

- Patient and family/caregiver education related to home blood pressure monitoring (HBPM) should include information about hypertension, selection of equipment, appropriate procedures, and interpretation of results (Whelton et al., 2018).
- Automated blood pressure devices in public locations are generally inaccurate and inconsistent. In addition, the cuffs on these devices are inadequate for people with large arms (Pickering et al., 2005).
- Explain to the patient that it is important to use a cuff size appropriate for limb circumference. Inform the patient that cuff sizes range from a pediatric cuff to a large thigh cuff and that a poorly fitting cuff can result in an inaccurate measurement.
- Use of an automated validated digital monitoring device is suggested as best practice for HBPM (Whelton et al., 2018). Inform the patient about digital blood pressure monitoring equipment. Although more costly than manual cuffs, most provide an easy-to-read recording of systolic and diastolic measurements. Use of auscultatory devices is not recommended for HBPM because patients, family, and/or caregivers rarely master the technique required for accurate use of these devices (Whelton et al., 2018).
- Optimally, patients should measure and record blood pressure daily. Explain that two readings, at least 1 minute apart, should be taken in the morning before taking medications and in the evening (Muntner et al., 2019; Whelton et al., 2018). Measurement should occur following the guidelines detailed in Skill 26-4. Ideally, patients should measure weekly blood pressure readings beginning 2 weeks after a change in the treatment regimen and during the week before a follow-up visit (Whelton et al., 2018). The readings should be recorded to show to the health care provider. If possible, monitor with built-in memory should be brought to all health care visits.
- Explain that home monitoring devices should be checked for accuracy every 1 to 2 years. Readings should be compared with auscultated measurement by a health care provider to ensure accuracy.

Skill 26-5 Assessing Blood Pressure by Auscultation

DELEGATION CONSIDERATIONS

The measurement of brachial artery blood pressure may be delegated to assistive personnel (AP) as well as to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- Stethoscope
- Sphygmomanometer
- Blood pressure cuff of appropriate size
- Electronic record or pen and paper or flow sheet
- Alcohol swab

- PPE, as indicated

IMPLEMENTATION

ACTION	RATIONALE
1. Check the prescribed interventions or plan of care for frequency of blood pressure measurement. More frequent measurement may be appropriate based on nursing judgment.	Provides for patient safety.
 2. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 3. Identify the patient.	Identifying the patient ensures the right patient receives the intervention and helps prevent errors.
4. Close the curtains around the bed and close the door to the room, if possible. Discuss the procedure with the patient and assess patient's ability to assist with the procedure. Instruct the patient to hold the limb still and refrain from speaking during the measurement. Validate that the patient has relaxed for several minutes.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates cooperation. Keeping the limb still and refraining from talking provide for accurate measurement of BP levels (Muntner et al., 2019). Activity immediately before measurement can result in inaccurate results.
5. Put on gloves, if indicated.	Gloves prevent contact with blood and body fluids. Gloves are usually not required for measurement of blood pressure, unless contact with blood or body fluids is anticipated.
6. Select the appropriate arm (or alternate site) for measurement and blood pressure cuff (refer to Table 26-8).	Decision on measurement site and cuff size is based on nurse's assessment of individual patient circumstances. Incorrect cuff size contributes to the most frequent error in measurement in nonacute care settings (Muntner et al., 2019).
7. Have the patient assume a comfortable lying or sitting position with the forearm supported at the level of the heart and the palm of the hand upward (Fig. 1). If the measurement is taken in the supine position, support the arm with a pillow. In the sitting position, support the arm yourself or by using the bedside table. If the patient is sitting, have the patient sit back in the chair so that the chair supports their back. In addition, make sure the patient keeps the legs uncrossed.	The position of the arm can have a major influence when the blood pressure is measured; if the upper arm is below the level of the right atrium, the readings will be too high. If the arm is above the level of the heart, the readings will be too low (Muntner et al., 2019; Pickering et al., 2005). This position places the brachial artery on the inner aspect of the elbow so that the bell or diaphragm of the stethoscope can rest on it easily. Support for the patient's arm prevents isometric exercise that will affect the BP level (Muntner et al., 2019). If the back is not supported, the diastolic pressure may be elevated falsely; if the legs are crossed, the systolic pressure may be elevated falsely (Muntner et al., 2019; Pickering et al., 2005).
8. Expose the brachial artery by removing garments or move a sleeve if it is not too tight, above the area where the cuff will be placed.	Clothing over the artery interferes with the ability to hear sounds and can cause inaccurate blood pressure readings. A tight sleeve would cause congestion of blood and possibly inaccurate readings (Muntner et al., 2019).
9. Palpate the location of the brachial artery. Center the bladder of the cuff over the brachial artery, about	Pressure in the cuff applied directly to the artery provides the most accurate readings. If the cuff gets

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

midway on the upper arm, so that the lower edge of the cuff is about 2.5 to 5 cm (1 to 2 inches) above the inner aspect of the elbow. **Line up the artery marking on the cuff with the patient's brachial artery.** The tubing should extend from the edge of the cuff nearer the patient's elbow (Fig. 2).

in the way of the stethoscope, readings are likely to be inaccurate. A cuff placed upside down with the tubing toward the patient's head may give a false reading.

FIGURE 1. Positioning for blood pressure assessment using brachial artery. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

FIGURE 2. Placing the blood pressure cuff on the upper arm. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

10. Wrap the cuff around the arm smoothly and snugly, and fasten it. Do not allow any clothing to interfere with the proper placement of the cuff.

A smooth cuff and snug wrapping produce equal pressure and help promote an accurate measurement. A cuff wrapped too loosely results in an inaccurate reading.

11. Check that the needle on the aneroid gauge is within the zero mark (Fig. 3).

If the needle is not in the zero area, the blood pressure reading may not be accurate.

FIGURE 3. Ensuring gauge starts at zero. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

Estimating Systolic Pressure

12. Palpate the pulse at the brachial or radial artery by pressing gently with the fingertips (Fig. 4).

To identify the first Korotkoff sound accurately, the cuff must be inflated 20 to 30 mm Hg above the point at which the pulse can no longer be felt (Muntner et al., 2019).

FIGURE 4. Palpating the brachial pulse. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

13. Tighten the screw valve on the air pump.	The bladder within the cuff will not inflate with the valve open.
14. **Inflate the cuff while continuing to palpate the artery. Note the point on the gauge where the pulse disappears.**	The point where the pulse disappears provides an estimate of the systolic pressure. To identify the first Korotkoff sound accurately, the cuff must be inflated to a pressure above the point at which the pulse can no longer be felt.
15. Deflate the cuff and wait 1 minute.	Allowing a brief pause before continuing permits the blood to refill and circulate through the arm.

Obtaining Blood Pressure Measurement

16. Assume a position that is no more than 3 ft away from the gauge.	A distance of more than about 3 ft can interfere with accurate reading of the numbers on the gauge.
17. Place the stethoscope earpieces in your ears. Direct the earpieces forward into the canal and not against the ear itself.	Proper placement blocks extraneous noise and allows sound to travel more clearly.
18. Place the bell or diaphragm of the stethoscope firmly but with as little pressure as possible over the brachial artery (Fig. 5). Do not allow the stethoscope to touch clothing or the cuff.	Having the bell or diaphragm directly over the artery allows more accurate readings. Heavy pressure on the brachial artery distorts the shape of the artery and the sound. Placing the bell or diaphragm away from clothing and the cuff prevents noise, which would distract from the sounds made by blood flowing through the artery.

FIGURE 5. Placement of diaphragm of stethoscope. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

19. Pump the pressure 20 to 30 mm Hg above the point	Increasing the pressure above the point where the pulse

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

at which the systolic pressure was palpated and estimated. Open the valve on the manometer and allow air to escape slowly (allowing the gauge to drop 2 mm Hg per second) (Muntner et al., 2019).

disappeared ensures a period before hearing the first sound that corresponds with the systolic pressure. It prevents misinterpreting phase II sounds as phase I sounds.

20. **Note the point on the gauge at which the first of at least two consecutive beats appears (Fig. 6). Read the pressure to the closest 2 mm Hg. Note this number as the systolic pressure.**

Systolic pressure is the point at which the blood in the artery is first able to force its way through the vessel at a similar pressure exerted by the air bladder in the cuff. The first sound is phase I of Korotkoff sounds.

21. Do not reinflate the cuff once the air is being released to recheck the systolic pressure reading.

Reinflating the cuff while obtaining the blood pressure is uncomfortable for the patient and can cause an inaccurate reading. Reinflating the cuff causes congestion of blood in the lower arm, which lessens the loudness of Korotkoff sounds.

22. **Note the point at which the sound completely disappears (Fig. 7). Read the pressure to the closest 2 mm Hg. Note this number as the diastolic pressure.**

The point at which the sound disappears corresponds to the beginning of phase V Korotkoff sounds and is generally considered the diastolic pressure reading (Muntner et al., 2019; Pickering et al., 2005).

FIGURE 6. Noting the point on the gauge at which the first of at least two consecutive beats appears. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

FIGURE 7. Noting the point at which the sound completely disappears. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud*.)

23. Allow the remaining air to escape quickly. Repeat any suspicious reading, but wait at least 1 to 2 minutes. Deflate the cuff completely between attempts to check the blood pressure.

False readings are likely to occur if there is congestion of blood in the limb while obtaining repeated readings.

Removing gloves properly reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents the spread of microorganisms.

24. When measurement is completed, remove the cuff. Remove gloves, if worn. Perform hand hygiene. Cover the patient and help them to a position of comfort.

Covering and positioning the patient ensures patient comfort.

25. Clean the bell or diaphragm of the stethoscope with the alcohol wipe. Clean and store the sphygmomanometer, according to facility policy.

Appropriate cleaning deters the spread of microorganisms. Equipment should be left ready for use.

Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene deters the spread of microorganisms.

26. Remove additional PPE, if used. Perform hand hygiene.

DOCUMENTATION

Guidelines

Record the findings on the electronic record or flow sheet. Communicate abnormal findings to the primary health care

provider. Identify arm used and site of assessment if other than brachial.

Sample Documentation

Practice documenting blood pressure and other vital signs in *Lippincott DocuCare*.

10/18/25 0945 Blood pressure taken in right arm 180/88. Patient denies headache, dizziness. Dr. Brown notified. Captopril 25 mg PO twice per day prescribed. Blood pressure to be repeated 30 minutes after administering medication.

—M. Evans, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

SPECIAL CONSIDERATIONS

General Considerations

- It is recommended that blood pressure measurements be checked in both arms at the first examination (Muntner et al., 2019; Pickering et al., 2005). Most people have differences in blood pressure readings between arms. When there is a consistent interarm difference, use the arm with the higher pressure (Muntner et al., 2019; Pickering et al., 2005). Separate repeated blood pressure measurements in the same arm by 1 to 2 minutes to avoid inaccurate results (Muntner et al., 2019).
- Incorrect cuff size contributes to the most frequent error in measurement in nonacute care settings (Muntner et al., 2019). *If the cuff is too narrow*, the reading could be erroneously high because the pressure is not evenly transmitted to the artery. *If a cuff is too wide,* the reading may be erroneously low because pressure is dispersed over a disproportionately large surface area.
- Blood pressure can be assessed using an automatic electronic blood pressure monitor (see Skill 26-4); systolic blood pressure can be assessed using Doppler ultrasound.
- Diastolic blood pressure measured while the patient is supine is approximately 1 to 5 mm Hg higher than when measured while the patient is sitting; systolic blood pressure measured while the patient is supine is approximately 3 to 10 mm Hg higher than when measured while the patient is sitting (Muntner et al., 2019).
- The wrist site for measurement has been suggested as an alternative for obtaining blood pressure readings in people who are obese. It is often difficult to obtain the appropriately sized cuff for the upper arm, given arm circumference and conical-shaped upper arms common in obesity. The conical shape of the upper arm makes it difficult to fit the cuff to the arm, increasing the likelihood of inaccurate blood pressure measurement (Halm, 2014). Thus, measurement in the forearm can be a possible solution to this problem (Muntner et al., 2019; Palatini, 2018).
- When the patient's brachial artery is inaccessible and/or the use of the upper arm is contraindicated, you can assess the blood pressure using the popliteal artery in the leg. The systolic blood pressure is at least 15 to 20 mm Hg higher at this site than the arm, although the diastolic pressure is the same (Muntner et al., 2019; Sheppard et al., 2019).

Infant and Child Considerations

- In children, if elevated blood pressure is present when measuring with an oscillometric device, auscultation should be performed to define blood pressure levels (Muntner et al., 2019).
- Blood pressure should be taken in the right arm for children to align with normative data (Muntner et al., 2019).
- In infants and small children, the lower extremities are commonly used for blood pressure monitoring at the popliteal, dorsalis pedis, and posterior tibial sites. In children older than 1 year of age, the systolic pressure in the thigh tends to be 10 to 40 mm Hg higher than in the arm; the diastolic pressure remains the same (Kyle & Carman, 2021).
- Infants and children presenting with cardiac complaints may have blood pressures assessed in all four extremities. Large differences among blood pressure readings between the upper and lower extremities can indicate heart defects, such as coarctation of the aorta (Kyle & Carman, 2021).

Community-Based Care Considerations

- Patient and family/caregiver education related to home blood pressure monitoring (HBPM) should include information about hypertension; selection of equipment; appropriate procedures; and interpretation of results (Whelton et al., 2018).
- Automated blood pressure devices in public locations are generally inaccurate and inconsistent. In addition, the cuffs on these devices are inadequate for people with large arms (Pickering et al., 2005).
- Use of an automated validated digital monitoring device is suggested as best practice (Whelton et al., 2018). Use of auscultatory devices is not recommended for HBPM because patients, family, and/or caregivers rarely master the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

technique required for accurate use of these devices (Whelton et al., 2018). Refer to information in Skill 26-4.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Take your own pulse several times a day, such as when you first get up, before and after meals, and before and after exercise. Write down the rate, rhythm, and quality of the pulse. What changes did you see? What are the physiologic rationales for these changes?

. Describe differences you might expect to find in the vital signs of the following individuals, and include the physiologic reasons for these differences:

- A teenager who has his first football practice in 95°F (35°C) heat
- An infant with a bacterial ear infection
- A young woman arriving at the emergency department after an attempted assault
- A middle-aged man who sustained serious trauma and bleeding in an automobile crash
- A 92-year-old woman with a chronic respiratory disease

PRACTICING FOR NCLEX

. A nurse receives information during shift report that a patient is afebrile. What action will the nurse take in response?

a. Checking the MAR for prescribed antipyretic medication
b. Reporting the finding to the primary care provider
c. Taking the patient's temperature using a different method
d. No action is necessary; this is a normal reading

. A nurse is assessing the vital signs of a group of patients in the emergency department. Which patients require follow-up by the nurse? Select all that apply.

a. Infant whose temperature is 100.5°F (38.1°C)
b. Toddler whose blood pressure is 118/80
c. School-age child whose temperature is 102.2°F (39°C)
d. Adolescent whose pulse rate is 70 beats/min
e. Adult whose respiratory rate is 20 breaths/min
f. Older adult whose pulse rate is 42 beats/min

. A nurse is caring for a newborn with hypothermia. What action does the nurse take to prevent heat loss from convection?

a. Wrapping the newborn in a blanket
b. Placing the newborn on a warmed surface
c. Reducing the temperature in the room
d. Increasing the temperature in the room

. A charge nurse working on a medical-surgical unit stops the AP from taking rectal temperatures on patients with which problems? Select all that apply.

a. Hypothermia
b. Pneumonia
c. Bradycardia
d. Leukemia
e. Thrombocytopenia
f. Pancreatitis

. While taking an adult patient's pulse, a nurse obtains a heart rate of 140 beats/min. What should the nurse do next?

a. Reassess the pulse in 1 hour
b. Measure the blood pressure
c. Document the information, noting tachycardia
d. Report the rate to the health care provider

. During assessment of vital signs, a patient reports severe abdominal pain. Which pain-related changes in vital signs may be present? Select all that apply.

a. Pulse rate of 102
b. Body temperature 98.8°F
c. Blood pressure 154/86
d. Increased respiratory depth

e. Respiratory rate of 24
f. Body temperature 100.8°F

. A nurse is caring for a group of patients on a cardiac unit. Which finding will prompt the nurse to assess the apical–radial pulse?
a. Bounding radial pulse
b. Immediately postoperative
c. Rapid, irregular pulse
d. Fluid volume deficit

. A nurse is assessing the blood pressure of a patient with traumatic injuries using a Doppler device. Which information does the nurse expect to obtain?
a. Amplitude of the brachial pulse
b. Mean arterial blood pressure
c. Estimation of the systolic blood pressure
d. Apical–radial pulse rate

. A nurse enters a room and finds a patient who is unable to catch their breath, has a respiratory rate of 28, and is using accessory muscles to breathe. What intervention will the nurse use to relieve dyspnea?
a. Remove pillows from under the head
b. Raise the head of the bed
c. Elevate the foot of the bed
d. Reassess the respiratory rate

. A nurse has assessed an older adult for orthostatic hypotension as shown in the electronic health record (EHR). What action will the nurse take?
Exhibit: Electronic health record (EHR)
Graphic sheet
8:00 AM BP lying 124/76
BP sitting 118/74
BP standing 98/58
a. Encourage the patient to rise from a sitting position quickly to improve blood flow
b. Suggest that in the future the patient "dangle" for a few minutes before standing
c. Return the patient to bed and place them in Fowler position
d. Administer medication to increase blood pressure

. A nurse is caring for a postoperative patient who experienced hypovolemic shock necessitating transfer to the ICU. The nurse manager reviews the medical record and suspects which situation contributed to the emergency?
Exhibit: Electronic health record (EHR)
Graphic sheet
2:00 PM T 99.2, P 88, RR 16, BP 106/54
2:15 PM T 99.6, P 94, RR 16, BP 100/52
2:30 PM T 99.4, P 110, RR 18, BP 96/50
2:45 PM T 99.2, P 120, RR 20, BP 84/48
a. Using an inappropriate format to document the vital signs
b. Failing to report tachycardia and hypotension to the provider
c. Not following the postoperative vital sign protocol
d. Failing to reflect a pain assessment in the documentation

. A patient has a blood pressure reading of 130/90 mm Hg during a clinic visit. What recommendation for follow-up will the nurse make?
a. Follow-up measurements of blood pressure
b. Immediate treatment by a health care provider
c. No action, because the nurse considers this reading is due to anxiety
d. Change in dietary intake

. A nurse participating in community blood pressure screening tells the patient their blood pressure is 120/80 mm Hg. When the patient asks what the numbers mean, what information does the nurse provide?
a. Rhythmic distention of the arterial walls from increased pressure due to surges of blood with ventricular contraction
b. Systolic pressure represents ventricular contraction causing high pressure on arterial walls; the bottom number or diastolic pressure reflects ventricular relaxation with a lower pressure on the arteries
c. Normal blood pressure

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

d. Difference between the pressure on arterial walls with ventricular contraction and relaxation

. A nurse observes a nursing student is taking the blood pressure on a patient with a cuff that is too large for the patient's arm. What explanation does the nurse give to the student for why errors of measurement may result?

a. "Using the wrong cuff will result in an incorrect reading."
b. "This cuff will cause an elevation in diastolic blood pressure."
c. "Using the wrong cuff will cause dangerous pressure on the arm."
d. "An overly large cuff will cause an inaccurate low reading."

. A nursing student is caring for a patient who has intravenous fluids infusing in the right arm. What action will the student take to correctly obtain the blood pressure?

a. Take the blood pressure in the right arm
b. Assess blood pressure using the left arm
c. Use the smallest possible cuff
d. Document an inability to take the blood pressure

. The nurse must assess a patient's blood pressure using a thigh cuff, due to presence of a right antecubital IV and a left arm dialysis access. Which of these arteries will the nurse use for auscultation?

a. Brachial
b. Carotid
c. Popliteal
d. Radial

ANSWERS WITH RATIONALES

. **d.** Afebrile means without fever, or a temperature is within the normal range. No additional actions are needed.

. **a, d, e, f.** The normal temperature range for infants is 98.7° to 100.5°F (37.1° to 38.1°C). The normal pulse rate for an adolescent is 55 to 105. The normal respiratory rate for an adult is 12 to 20 breaths/min and the normal pulse for an older adult is 40 to 100 beats/min. The normal blood pressure for a toddler is 89/46, and the normal temperature for a child is 98.2° to 100°F (36.8° to 37.8°C; refer to Table 26-1).

. **a.** Convection refers to heat disseminated by motion between areas of unequal density, for example, a fan blowing cool air over the body or an uncovered body. Placing the baby on a warmed surface would prevent heat loss via conduction. Reducing the temperature may decrease heat loss via perspiration (evaporation); increasing the temperature in the room may increase heat loss via evaporation.

. **c, d, e.** The rectal site should not be used in newborns, children with diarrhea, and in patients who have undergone rectal or vaginal surgery. Inserting a rectal thermometer can stimulate the vagus nerve causing or worsening bradycardia; this route may be contraindicated in certain cardiac patients. The rectal route is also contraindicated in patients who have neutropenia (low white blood cell counts, such as in leukemia or those receiving chemotherapy), thrombocytopenia (low platelet counts), and certain neurologic disorders.

. **d.** A pulse rate of 140 beats/min in an adult, tachycardia, is abnormally fast, and should be reported to the primary nurse or health care provider immediately. Tachycardia at rest often reflects an underlying issue and can lead to decreased tissue perfusion; additional assessments are needed.

. **a, c, e.** The pulse, blood pressure, and respiratory rate often increase when a person is experiencing pain; respiratory depth decreases. Pain does not affect body temperature.

. **a.** The nurse assesses the apical–radial pulse when dysrhythmia exists or is suspected, manifested by tachycardia or irregular pulse. The difference between the apical and radial pulse rates, called the pulse deficit, captures heart beats not reaching the peripheral arteries.

. **b.** A Doppler provides an estimation of the systolic blood pressure when the pulse is inaudible. Diastolic pressure cannot be calculated because oscillations of the pulse will be audible during the entire BP assessment; recall the nurse can auscultate a pulse with the Doppler. The pulse amplitude obtained with palpation, the mean arterial pressure reflects the average blood pressure during a cardiac cycle, and the apical–radial pulse is assessed to detect a pulse deficit, often present with a dysrhythmia.

. **b.** Elevating the head of the bed facilitates lung expansion by allowing the abdominal contents to descend, which facilitates lung expansion and oxygenation. Elevated respiratory may occur due to distress or hypoxemia; assessing the respiratory rate does not resolve the problem of dyspnea.

. **b.** Allowing the patient to "dangle" on the edge of the bed prior to rising may prevent orthostatic hypotension, by allowing time to adjust to the upright position. Arising and moving about slowly, especially after a period of bed rest, might also prevent orthostatic hypotension. If a patient becomes dizzy or faint, the nurse should return the patient to bed and place them in a supine position, which restores blood flow to the brain. A β-blocker is given to decrease blood pressure for a patient with hypertension; the nurse will question this prescription when hypotension is present.

. **b.** Pathologic hypotension, especially when associated with tachycardia, can result from vasodilation of the arterioles, failure of the heart to pump effectively, loss of blood (such as with a hemorrhage or shock), or poor oxygenation. The nurse reports such changes to the health care provider immediately and anticipates prescriptions to restore perfusion.

. **a.** A single blood pressure reading that is mildly elevated is not significant, but the measurement should be monitored over time to determine if hypertension exists. The nurse will recommend a follow-up visit with the health care provider for a recheck.

. **c.** The systolic pressure, 120 mm Hg, occurs when ventricular contraction causes the highest pressure on arterial walls. The diastolic pressure, 80 mm Hg, correlates with the lowest pressure on arterial walls as the heart rests between beats. The difference between systolic and diastolic pressures is called the pulse pressure. The rhythmic distention of the arterial walls as ventricular contraction pumps blood to the body creates the pulse.

. **a.** A blood pressure cuff that is too large will cause a falsely low reading; a cuff that is too small will cause a falsely high reading. The wrong size cuff will not injure the patient, but pressure may be felt on the arm from a too tight cuff.

. **b.** The blood pressure should be taken in the arm opposite of the arm with intravenous access or infusion.

. **c.** When the patient's brachial artery is inaccessible and/or the use of the upper arm is contraindicated, blood pressure can be assessed using the popliteal artery of the leg. The blood pressure in that area, in both adults and children, is generally higher.

Health Assessment

Billy Collins

Billy, a 9-year-old boy with a history of allergies, including an allergy to insect stings, is spending a week at summer camp. He reports to the camp counselor that he was just stung by a bee.

Tammy Browning

Tammy, who is expecting her first child, has arrived at the birthing center in labor. She and her partner, both in their late 20s, have a history of substance abuse, primarily alcohol and marijuana. A urine specimen is to be collected for routine evaluation and a drug screen. Tammy is unaware that drug testing will be done.

Ramona Lewis

Ramona, a 22-year-old college student, was recently discharged from the inpatient unit with a diagnosis of anorexia nervosa. She is living with her partner, Karen, and her mother, in her mother's home. A home health nurse is visiting Ramona for follow-up services.

Additional patient scenarios available in *Lippincott DocuCare*.

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Explain the components, purposes, and types of health assessments.
. Prepare the patient and the environment for a health assessment.
. Conduct a health history.
. Use the techniques of inspection, palpation, and auscultation appropriately during a physical assessment.
. Conduct a physical assessment in a systematic manner.
. Document health assessment findings in a concise, descriptive, and legally appropriate manner.
. Describe nursing responsibilities related to diagnostic and laboratory testing as part of health assessment.

Conducting a health assessment involves collecting, validating, and analyzing subjective data and objective data to determine the patient's overall level of physical, psychological, sociocultural, developmental, functional, and spiritual health. Subjective data are based on patient experiences and perceptions, are known only by the patient (e.g., pain and nausea), and are reported by the patient (the patient's own words; sensations, symptoms, perceptions, desires, preferences, beliefs, ideas, values, and personal information). Objective data are measurable and are directly observed or elicited through general observation and physical examination (physical characteristics, body functions, and measurements [blood pressure, height, respiratory rate], appearance, behavior, laboratory results). Objective data may also be obtained through the patient's health record and observations reported by the patient's family, significant others, or care givers about the patient (Weber & Kelley, 2018).

Although most components of a health assessment are described in this chapter, some of the assessments included in a comprehensive or focused examination (such as an internal eye examination, a vaginal examination, or a rectal examination) are usually carried out by advanced practice professionals, health care providers with advanced education. Refer to a health assessment text for details of these advanced assessment skills.

HEALTH ASSESSMENT

Nursing health assessment involves gathering information about the health status of the patient. The nurse then evaluates and synthesizes the information (**data**). The nurse plans appropriate nursing interventions based on this data and evaluates patient care outcomes to deliver the best possible care for each patient. A health assessment includes a health history and a physical assessment. A **health history** is a collection of subjective information that provides information about the patient's health status. **Physical assessment** is a collection of objective data that provides information about changes in the patient's body systems.

A health assessment may be comprehensive, ongoing or partial (follow-up), focused, or emergency. The amount and type of information collected and frequency of assessment vary based on the patient's needs and health care setting and circumstances (Jensen, 2019). Nursing knowledge, expertise, judgment, and clinical experience guide decisions about which assessments are a priority for an individual patient and health care situation.

A **comprehensive health assessment** is broad and includes a complete health history and physical assessment. A comprehensive assessment is usually conducted when a patient first enters a health care setting, with information providing a baseline for comparing later assessments. An **ongoing or partial health assessment**, or **follow-up assessment**, is one that is conducted at regular intervals (e.g., at the beginning of each home health visit or each hospital shift) during care of the patient. This type of assessment concentrates on identified health problems to monitor positive or negative changes and evaluate the effectiveness of interventions. In addition, a brief reassessment of the patient's body systems and functional abilities is performed to detect any new problems (Weber & Kelley, 2018).

Clinical nurses must be organized and focused to complete meaningful health assessment, usually a partial health assessment, on all assigned patients within the first hour of the nursing shift (Haugh, 2015). This requires the nurse to assess each patient quickly and efficiently, incorporating assessments directed at basic bodily functions as well as assessment based on individual patient priorities. Nurses must use clinical judgment to adapt this assessment for each patient and based on the patient population served (Haugh, 2015). Any additional in-depth information about the patient can be obtained once the baseline status for each patient has been established. This prioritized initial assessment may also identify specific findings to follow-up on later. Box 27-1 (on page 776) provides an example of a brief, general assessment that can be used to gather pertinent data to be used provide a basis for prioritizing nursing care. Nurses should use clinical judgment to adapt this generic assessment to the individual circumstances of an individual patient and to monitor for changes that might require further intervention (Haugh, 2015).

A **focused health assessment** is conducted to assess a specific health issue. This type of assessment "usually involves one or two body systems and is smaller in scope than a comprehensive assessment, but more in depth on the specific issue or issues" (Jensen, 2019, p. 10). For example, if a woman is having abdominal pain, the nurse asks questions about urinary problems, bowel problems, allergies, and menstrual history during the health history and then assesses vital signs and abdominal structures during the physical assessment. Focused assessments may also be used to address the immediate and highest priority concerns for an individual patient.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

I have always been interested in labor and delivery, so I was very excited to have the opportunity to follow a nurse in labor and delivery and assist and witness the beginning of life. I had no idea that the whole process could be so complicated.

It was here that I met Tammy Browning, who was expecting her first child. She and her partner were in their late 20s or early 30s. She was in labor and had arrived at the birth center late last night. Before entering the room, the nurse gave me a brief rundown of what we were expected to do throughout the

morning.

On entering the patient's room for the first time, I was shocked at what I saw. The room was dark and extremely cluttered with food, candy wrappers, and trash overflowing onto the floor. The patient's partner had been sleeping in the room and both of their belongings were all over the place. I could not believe it! When we left the room, the nurse told me that both the patient and her partner had a history of drug use, mainly alcohol and marijuana. We had to get a urine sample from her to do a dipstick test. The specimen was also going to be used for a drug screen, but the patient was not going to be told about this. I was shocked and confused by this action. I thought that we had to tell the patient everything we were going to do—right?

Thinking Outside the Box: Possible Courses of Action

- Go along with what the nurse decided to do, and when we get out of the patient's room, ask why she decided to take this course of action.
- Inform myself of the legality of taking this route of action.
- Inform my instructor and head nurse about the case, asking if this was a usual occurrence and requesting that they tell or educate me on what basis they were allowed to do this.

Evaluating a Good Outcome: How Do I Define Success?

- Safety of patient and neonate is ensured.
- Patient and baby benefit from the decided-on course of action.
- No breach of duty or harm is done.
- Patient receives proper care and treatment regardless of her past drug use and results of the drug tests.
- Respect for patient is maintained.

Personal Learning: Here's to the Future!

I really had no idea what to do. Because I did not feel legally competent to challenge the nurse and suggest a different course of action, I followed her and went along with her story. Afterward, I asked her if we were allowed to do this. Her answer was that she was doing it because the patient had a history of drug use and she suspected that she had been smoking marijuana up to the time she arrived. The test was not going to harm the baby or the mother; if anything, the test was going to be beneficial in providing the most adequate care for her and her baby. It was also going to assist in preparing for any complications that may arise during the delivery.

When she gave me this explanation, I figured that her reasons were valid and it was all right to do this since no one was going to get hurt and it would be beneficial. However, I was left with the thought that we were violating the patient's privacy. I also spoke with my clinical instructor about the situation. Through this experience, I realized that I need to educate myself more on the legal aspects of nursing. I had never paid much attention to the fact that I am exposed to many legal situations every day as a health care provider. Therefore, I must be prepared to confront them. I think that it is vital to be skilled as well as to be competent medically and legally. By having this knowledge, many difficult situations may be avoided and/or resolved. With this knowledge, I will also be a better advocate for my patients.

Stephanie Cuellar, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Are there any other criteria that would be appropriate to use? Did the nursing student meet the criteria? Why or why not? What knowledge, skills, and attitudes do you need to develop to continuously improve the quality and safety of care for patients like Ms. Browning?

Patient-Centered Care: What do you think might have happened if the patient were told about the drug testing? Do you feel that the nurse's action of not telling the patient was based on appropriate ethical and legal principles? Why or why not? If so, what ethical and legal principles formed the basis for the action? If not, what ethical and legal principles were violated?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to improve

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

to ensure that you function as a member of the patient care team? What skills do you need to implement effective strategies for communicating and resolving conflict? What skills do you need to assert your own position/perspective in discussions about patient care?

Safety/Evidence-Based Practice: What evidence in nursing literature provides guidance for decision making regarding care of this patient?

Informatics: Can you identify the essential information that must be available in Ms. Browning's electronic health record to support safe patient care and coordination of care? Can you identify the appropriate process to protect confidentiality of protected health information in the patient's health records? Can you think of other ways to respond to or approach the situation?

Box 27-1 Brief General Physical Assessment

Type of Assessment	Assessment Components
Safety	Bed position, call bell location, appropriate emergency equipment, assistive devices, fall risk/hazards
Vital signs	Temperature, pulse, respirations, blood pressure, oxygen saturation, pain assessment
Mental status	Level of consciousness; orientation to person, place, and time; speech
Psychosocial	Behavior and affect
Head, eyes, ears, nose	Eyes, pupils, mouth, carotid arteries, swallowing, throat, neck facial color, moisture, lesions, wounds, glasses, hearing aid, ability to hear conversation, ability to see
Chest	Chest color, moisture, lesions, wounds, quality of respirations, heart sounds, lung sounds, cough, sputum
Abdomen	Abdomen color, moisture, lesions, wounds, bowel sounds, tenderness, distention, pain/discomfort, ability to eat, urine elimination pattern and urine characteristics, bowel elimination pattern, and stool characteristics
Upper and lower extremities	Skin, color, pulses, temperature, tenderness, edema, capillary refill, strength, sensation, range of motion, lesions, wounds
Activity	Movement and ambulation, ability to move in bed, ability to get out of bed, ability to walk and distance, gait
Therapeutic devices	Peripheral and central venous access devices, supplemental oxygen setting, pacemaker, cardiac monitor, urinary catheters, gastric tubes, chest tubes, dressings, braces, slings

Nurses should use clinical judgment to adapt this generic assessment to the individual circumstances of each patient and to monitor for changes that might require further intervention (Haugh, 2015).

Source: Adapted from Haugh, K. H. (2015). Head-to-toe: Organizing your baseline patient physical assessment. *Nursing*, *45*(12), 58–61, Wolters Kluwer. Reprinted from Elsevier: Anderson, B., Nix, E., Norman, B., & McPike, H. D. (2014). An evidence based approach to undergraduate physical assessment practicum course development. *Nurse Education in Practice*, *14*(3), 242–246; with permission from Elsevier.

An **emergency health assessment** is a type of rapid focused assessment conducted when addressing a life-threatening or unstable situation. Assessment of the airway, breathing, and circulation when encountering a patient with traumatic injury as a result of a motor vehicle accident is an example of an emergency assessment.

Consider **Billy Collins**, the 9-year-old who was stung by a bee. In this situation, the nurse would conduct an emergency assessment to determine the immediate effects of the bee sting, assessing for indications of an allergic reaction such as respiratory difficulty. Once this emergency assessment is completed and any immediate treatments initiated, the nurse would complete a health history to identify the boy's history of allergies and other relevant health issues.

Health assessment is an integral component of preventive health care. A preventive health assessment includes the patient's health history, risk for depression, functional ability, and level of safety; a physical examination; and patient education and counseling. Annual wellness visits include the patient's health history, blood pressure, height, weight, screening for cognitive impairment and potential risk factors related to depression, functional ability, and safety, as well as health education and preventive counseling. These services are part of the benefits offered for patients covered by Medicare, for example, as part of health promotion and disease prevention and detection (Centers for Medicare and Medicaid Services [CMS], 2018).

A nursing health assessment differs from other types of health assessments (e.g., one performed by a medical health care provider) in that it is a holistic collection of information about factors that affect or are affected by one's level of health. Nurses focus on how a person's health status is affecting activity levels and abilities to perform tasks, as well as how patients are coping with their health issues and any related loss of function or change in ability to function (Jensen, 2019). Accurate health assessment provides the foundation for therapeutic nursing care (Jensen, 2019). Health assessment is part of the foundation of the nursing process. The information from the nursing health assessment is used to formulate diagnoses or patient problems that require nursing care. Assessments are used to plan, implement, and evaluate teaching and care to promote an optimal level of health through interventions to prevent illness, restore health, and facilitate coping with disabilities or death. The information is also used to identify health problems that require interdisciplinary care or immediate referral to other health care providers.

This chapter provides information necessary to identify risks for or actual alterations in health, perform the skills of physical examination, and identify normal age-related variations in physical structures and functions. Health assessments are a part of nursing care for patients across the lifespan and may be conducted in any setting. Refer to the accompanying Reflective Practice box for an example. Additional information about assessment is found in Chapter 14.

Lifespan Considerations

A comprehensive assessment includes cognitive, psychosocial, and emotional development in addition to physical growth (Jensen, 2019). The nurse should identify growth and development patterns, expected variations and deviations from infancy through adolescence, adulthood, and into older age. Refer to Chapters 22, 23, and 24 for more information related to these assessments.

Cultural Considerations and Sensitivity

Each person is a unique individual. Culture influences a person's definition of health and illness (Jensen, 2019). Culture includes a person's racial or ethnic background and nonethnic culture, such as cultural identities based on socioeconomic status (e.g., culture of poverty), ability or disability (e.g., culture of the visually impaired), sexual orientation (e.g., LGBTQIA+ cultures), age (e.g., culture of the elderly), and occupational and professional cultures (e.g., culture of the military) (Jensen, 2019).

Nurses must consider patients within the context of family, culture, and community to meet the needs of an increasingly diverse population. Nurses and other health care professionals need to provide health care services in a sensitive, knowledgeable, and nonjudgmental manner with respect for people's health beliefs and practices, identifying patient specific needs based on the patient's current situation (Kersey-Matusiak, 2019). Nurses should be familiar with the general health beliefs and variances of various groups to improve the effectiveness of health care services and provide care within a cultural context. Nurses should know risk factors for alterations in health that are based on racial inheritance and ethnic backgrounds, as well as normal variations that occur within races. In addition, it is important to consider how cultural characteristics, such as religion and spirituality, may impact health. Cultural assessment is integrated into the overall assessment of the patient, family, and caregivers, incorporating questions aimed at gathering cultural data into the health assessment process (Andrews et al., 2020).

Concept Mastery Alert

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

All patients, regardless of their race or culture, have the same basic human needs. However, the nurse needs to keep in mind any cultural influences or factors affecting anatomy and physiology, health beliefs, and alterations in health.

Significant disparities exist for vulnerable populations, groups, and communities at a higher risk for poor health as a result of the barriers they experience to social, economic, political, and environmental resources. This also includes potential and actual limitations due to illness or disability (Joszt, 2018; National Collaborating Centre for Determinants of Health, 2020). For example, during the COVID-19 pandemic of 2020, groups of people were identified as vulnerable simply because of their specific risk of profound illness or even death with exposure to the virus. In 2020, these groups included people age 65 years and older; people of any age who have serious underlying medical conditions, such as chronic lung disease, diabetes, or liver disease, or who are obese or immunocompromised; and people with barriers to health care access, due to factors such as insurance status or immigration status (Berlinger et al., 2020; Centers for Disease Control and Prevention, 2020a). Cultural data, as part of health assessment, helps nurses identify patients who are most at risk and plan specific and individualized person-centered interventions that take mutually identified vulnerabilities into consideration. Vulnerable Population Alert 27-1 (on page 778) provides information and resources to support evidence-based practice related to an identified vulnerable population.

Chapter 5 provides information about cultural diversity, transcultural assessment, and the importance of providing culturally sensitive nursing care. Box 8-4 in Chapter 8 provides information about respectful ways to relate to patients from different cultures.

Patient Preparation

When conducting a nursing health assessment, it is important to consider and remain sensitive to the patient's physiologic needs (e.g., pain or decreased stamina because of age or illness) and psychological needs (e.g., anxiety about having the examination). Explain that the first part of the assessment will involve questions about the patient's health concerns, health habits, and lifestyle and that the information will only be shared with the patient's other health care providers. Inform the patient that after the health history is completed, body structures will be examined.

The patient may be anxious for various reasons. Reassure the patient by explaining that the assessments should not be painful. Explaining the assessment in general terms can help decrease the patient's embarrassment, fear of possible abnormal physical findings, or fear of "failing" a test. Be sure to then explain each assessment in greater detail as it is performed. Explain that drapes (covers) will be used during the examination, and only the area being assessed will be exposed. Answer the patient's questions directly and honestly.

Think back to **Ramona Lewis**, the college student who was recently discharged after treatment for anorexia nervosa. The nurse would need to incorporate knowledge of the emotional and physical effects of eating disorders when communicating with Ms. Lewis. In addition, the patient's anxiety is likely to be high; thus, using empathy, taking the time to explain things slowly, and establishing a trusting nurse–patient relationship are important.

Vulnerable Population Alert 27-1: Lesbian, Gay, Bisexual, Transgender, Questioning/Queer, Intersex, Ally/Asexual (LGBTQIA) Individuals

LGBTQIA individuals encompass all races and ethnicities, religions, and social classes (Healthy People 2020, n.d.). The LGBTQIA community is a vulnerable populace that accounts for 4.5% of the U.S. population (Aisner et al., 2020; The Williams Institute, UCLA School of Law, 2019). Research suggests that LGBTQIA individuals encounter health disparities linked to social stigma, discrimination, and denial of their civil and human rights (Healthy People 2020, n.d.). Fear of discrimination causes many LGBTQIA people to avoid seeking care and when they do get treatment, they are often not treated with the respect or cultural consideration that all patients deserve (Human Rights Campaign, n.d.). LGBTQIA health requires focused attention from health care and health care professionals to address health disparities, including:

- Increased risk for psychiatric disorders, substance abuse, and suicide
- LGBT youth are more likely to be homeless

- Increased experiences of violence and victimization
- Discrimination in access to health insurance, employment, housing, marriage, adoption, and retirement benefits
- Increased experiences of discrimination and prejudice
- Inadequate training and education contributing to a shortage of health care providers who are knowledgeable and culturally competent in LGBT health

Environmental Preparation

Privacy and respect for the patient are primary concerns when conducting a health assessment. In an outpatient setting, such as a clinic or primary care provider office, separate examination rooms provide a quiet, private space for assessment. Prepare the examination room before the health assessment is conducted by preparing the examination table, providing a gown and drape for the patient, and gathering instruments and special supplies needed for the assessment. In a hospital or community-based facility, the health assessment usually takes place in the patient's room. If the area is open to others, an enclosure with a curtain or screen is essential. The room should be warm enough to prevent chilling, and the area or room should be adequately lit, either by sunlight or overhead lighting.

When patients are seen in their home, an assessment may be performed in the patient's bedroom or another private area. Direct the patient to a private dressing area or to a comfortable area in the home and ask the patient to change into a gown, if possible.

For all settings, if necessary, assist the patient with undressing. Ask the patient to empty the bladder before the examination to promote patient comfort during the assessment and to facilitate assessment of the abdomen by the nurse.

Nurse's Role in Diagnostic and Laboratory Testing

Diagnostic procedures and laboratory tests provide crucial information about a patient's health; these results become a part of the total health assessment. Nurses assist before, during, and after some diagnostic tests, and complete other testing as prescribed. The nurse is also responsible for other activities associated with diagnostic tests, such as witnessing the patient's consent, scheduling the test, preparing the patient physically and emotionally for the test, providing care, and teaching the patient and/or caregivers about the prescribed procedures or tests.

Discussion of relevant diagnostic procedures and laboratory testing related to specific health issues can be found in each clinical chapter. Normal findings for many laboratory tests are found in Appendix C in online Student Resources for this text.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Consider **Tammy Browning**, the pregnant woman with a history of substance abuse. A urine specimen was to be obtained for routine testing. In addition, the specimen was to be used for drug testing without the patient's knowledge. Typically, a signed consent form is not necessary for urine specimens. However, the nurse would need to know the facility's policy and legal statutes of the area regarding consent for drug testing before obtaining the specimen.

HEALTH HISTORY

A health history is a collection of data that provides a detailed profile of the patient's health status. Nurses use therapeutic communication skills and interviewing techniques during the health history to establish an effective nurse–patient relationship and to gather data to identify actual and potential health problems as well as health-promotion activities and sources of strength. Effective interviewing skills are described in Chapters 8 and 14.

Information is collected during an interview with the patient, who is the primary source of data. The patient's family members and/or caregivers may also be an important source of data. They can sometimes offer insight that cannot be gained from patients who may be acutely ill, in pain, or cognitively impaired. Fawcett and Rhynas (2012) suggest, "Nurses need to balance the benefits of obtaining information from family members with the potentially conflicting motivations of patients and their families." The health records of the patient, if available, can also be used to collect additional information. Nurses should know and be sensitive to cultural differences that influence how both verbal and nonverbal communications are interpreted.

Components of the health history include biographical data, the reason the patient is seeking health care, present health or history of present health concern, past health history, family health history, functional health and a **review of systems** (a series of questions about all body systems that helps to reveal concerns or problems as part of the health history). The nurse should adapt questions to the individual patient, omitting questions that do not apply and adding questions that seem pertinent, based on the setting, situation, and ongoing information as the health assessment proceeds. Be sure to use language the patient can understand; avoid using medical terms and jargon. Refer to Focused Assessment Guide 27-1 (on page 780) for examples of appropriate questions related to these components. Examples of health history questions related to each body system (review of systems) are included in the discussion of each region of the physical examination later in the chapter.

Biographical Data

Depending on the health care setting, some biographical data may be collected by people other than the nurse. For example, someone in the admissions department or a receptionist in a medical office may obtain demographic data, including the patient's name, address, and billing and insurance information. Additional biographical information may include biologic sex, sexual orientation, gender identity, age and birth date, marital status, occupation, race, ethnic origin, religious preference, presence of an advance directive/living will, and the patient's primary health care provider. The source of the information is also recorded. Differences in language and culture may have an effect on the quality and safety of health care. Language has been identified as contributing to health disparities, as a significant barrier to access to health care, and a barrier to quality health care and appears to increase the risks to patient safety (Ali & Watson, 2018; Chung et al., 2020; Kersey-Matusiak, 2019; Ku & Jewers, 2013). Language barriers negatively impact the nurse's ability to effectively assess and meet patient care needs (Ali & Watson, 2018). It is important to note the patient's preferred language for discussing health care, as well as any sensory or communication needs. Hospitals are required to address unique patient needs, meet patient-centered communication standards, and comply with cultural competence requirements as outlined by The Joint Commission (2010; updated 2014). Box 8-4 in Chapter 8 provides information about respectful ways to relate to patients from different cultures, including communication techniques.

Reason for Seeking Health Care

The reason for requesting care is a statement in the patient's own words that describes the patient's reason for seeking care. This can help to focus the rest of the assessment. Ask an open-ended question, such as, "Tell me why you are here today." *Try to record whatever the person has to say in the person's exact words. Avoid paraphrasing or interpreting.* For example, if a patient comes into the clinic and tells you "I am having trouble sleeping. At night, I can't seem to stop my thoughts. All I do is worry," it is important to document the patient's own words. It would be incorrect to document

the following: “Patient complains of insomnia and anxiety.” Correct documentation may include the following: “Patient states, ‘I am having trouble sleeping. At night, I can’t seem to stop my thoughts. All I do is worry.’ ”

History of Present Health Concern

When taking the patient’s history of present health concern, be sure to explore the symptoms thoroughly. Encourage the patient to describe and explain any symptoms. The description should include information regarding the onset of the problem, location, duration, intensity, quality/description, relieving/exacerbating factors, associated factors, past occurrences, any treatments, and how the problem has affected the patient. Refer to Focused Assessment Guide 27-1 (on page 780) for examples of appropriate questions related to this component.

Past Health History

A patient’s past health history may provide insight into causes of current symptoms. It also alerts the nurse to certain risk factors. A past health history includes childhood and adult illnesses, chronic health problems and treatment, and previous surgeries or hospitalizations. This history should also include accidents or injuries, obstetric history, allergies, and the date of most recent immunizations. Vaccine recommendations are updated each year by the Centers for Disease Control and Prevention (CDC). Current guidelines for different age groups can be found on the CDC’s website at www.cdc.gov (CDC, n.d.a). Ask the patient about health maintenance screenings, such as routine mammograms and colorectal tests, including dates and results, as well as the use of safety measures. Ask the patient about prescribed and over-the-counter medications, including vitamins, supplements, and any home or herbal remedies. Include the name, dose, route, frequency, and purpose for each medication. Refer to Focused Assessment Guide 27-1 (on page 780) for examples of appropriate questions related to this component.

Focused Assessment Guide 27-1

HEALTH HISTORY

Factors to Assess	Questions and Approaches
Present health history	“When did you first begin having this problem?” “Did it happen suddenly or slowly?” “Show me exactly where you are having this problem.” “What other symptoms have you had with this problem?” “How have you treated this problem?”
Past health history	“Tell me about the childhood illnesses, such as measles or mumps, that you had.” “What are you allergic to?” “Describe any accidents, injuries, and surgeries you have had.” “What prescribed or over-the-counter medications do you use?” “Do you take any herbal or dietary supplements?” “What is the date of your most recent immunization for tetanus; pertussis; polio; measles; rubella; mumps; influenza; hepatitis A, B, and C; and pneumococcus?”
Family history	“How old are the members of your family?” “If any members of your family are not living, what caused their death?” “Is there any history of this health problem you have in other family members?” “Do any family members have long-term illnesses?”
Functional health	“Describe a typical day.” “Do you have difficulty or require assistance with bathing or dressing?” “Do you have difficulty or require assistance with toileting or moving around?” “Do you have difficulty or require assistance with eating or preparing meals?” “Do you have difficulty or require assistance with shopping or administering your own medications?” “Tell me about your driving. Who provides transportation?” “Do you have difficulty or require assistance with housekeeping, finances, or laundry?” “Do you smoke or drink alcohol? If so, what kind, for how long, and how much?” “Do you use recreational drugs such as marijuana, tranquilizers, crack, cocaine, or methamphetamine? If so, how much do you use and how often? Have you been exposed to any environmental toxins, such as pesticides, herbicides, or occupational chemicals? “Describe the foods you eat during a typical day.” “Tell me about your sleep patterns.” “How much exercise do you get each day?” “Who in your family or community is available to help you with health problems if you need it?” “What religious affiliations do you have?” “Does your religious faith or spirituality play an important part in your life?” “Tell me about how you deal with stress.” “Describe any changes that you have had in your mood or feelings.” “Have you ever been treated for any problems with your mood or behavior?” “How do you feel about the future?” “Do you feel unsafe in your home?” “Tell me about your use of seat belts in cars.” “Tell me about your family’s use of sports helmets, padding, or other protective equipment.” “Are you currently in a relationship? Are the aspects of sex satisfactory to you and your partner?”

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

QSEN EVIDENCE-BASED PRACTICE (EBP)

Health screening tests can identify health problems and diseases early when they are easier to treat. Individualized patient education is an important part of nursing care. Knowledge of current recommendations from reliable and expert sources is imperative when providing interventions and patient education related to health screening tests.

Family History

Information about a person's family history will provide insight into diseases and conditions for which an individual patient may be at increased risk. Certain disorders have genetic links. For example, a family history of cancer is a risk factor for cancer. Information regarding contact with family members with communicable diseases or environmental hazards can provide clues to the patient's current health or risk factors for health issues. For example, it would be important to note that a family member had recently recovered from pertussis (whooping cough), especially if the patient is presented with respiratory symptoms. This information can also identify important topics for health teaching and counseling. For example, if a child with asthma is living in a household with family members who smoke, the child is at great risk for exacerbations of the disease. Family counseling regarding asthma and smoking would be an important health care intervention. Refer to Focused Assessment Guide 27-1 for examples of appropriate questions related to this component.

Functional Health

Information about a patient's functional health helps to identify the effects of health or illness on a patient's self-care abilities and quality of life including the strengths of the patient and areas that need to improve (Jarvis & Eckhardt, 2020; Jensen, 2019). Psychosocial factors and lifestyle and health practices can contribute to and influence a patient's overall health and well-being. For example, smoking is related to many health problems. Discussion of one or more of these topics may cause strong personal reactions by a patient. It is very important to be nonjudgmental and explain why you need to know certain information (Hogan-Quigley et al., 2017). Consider assessing these factors at the end of the interview, because these issues may naturally arise during the review of systems and a trusting relationship has been established, making the discussion of personal issues easier (Jensen, 2019).

Social determinants of health, the conditions (social, economic, and physical) in the environments in which people live their lives, affect a wide range of health, functioning, and quality-of-life outcomes and risks (Healthy People 2030, n.d.). Ask about the patient's social support, interpersonal relationships, and resources for assistance. Ask about confidants, supporters, and people that are able to help the patient to cope with any health alteration, illness, or other change. Support provided by caregivers, family, friends, and social organizations can positively impact health promotion, improve coping with stress, enhance self-esteem, and support healthy lifestyle behaviors (Mayo Clinic, 2018a).

Ask about additional sociocultural factors that may impact a patient's health and use of health care, such as:

- Language barriers
- Literacy
- Limited access to food market and ability to obtain food
- Access to transportation
- Job opportunities
- Stable housing/safe environment

This information helps us to understand factors that may influence a patient's health and use of health care and shape more effective interventions (Healthy People, 2030, n.d.).

Ask about the patient's level of activity and exercise (Chapter 34), sleep and rest (Chapter 35), and nutrition (Chapter 37). Assess the patient's ability to perform **activities of daily living (ADLs)** or self-care activities. Eating, bathing, dressing, and toileting are examples of ADLs. Assess the patient's ability to perform **instrumental activities of daily living (IADLs)** or those activities needed for independent living. Housekeeping, meal preparation, management of finances, and transportation are examples of IADLs. Functional ability may be further assessed using a formal tool, such as the Katz Index of Independence in Activities of Daily Living, which is used with older adults. This tool can be found in Chapter 34. Refer to Focused Assessment Guide 27-1 for examples of appropriate questions related to these components.

Obtain information related to the patient's values, beliefs, and spiritual resources (Chapter 47); self-esteem and self-concept (Chapter 42); and coping and stress management (Chapter 43). Ask about personal habits, including use of alcohol, illicit drugs, and/or tobacco; exposure to environmental and occupational hazards; and intimate partner and family/caregiver (domestic) violence. Intimate partner violence (IPV) is physical violence, sexual violence, stalking, or psychological harm by a current or former partner or spouse, which can occur among heterosexual or same-sex couples and does not require sexual intimacy (Centers for Disease Control and Prevention [CDC], 2018). The Focused

Assessment Guide 27-1 provides examples of appropriate questions related to these components. Refer to Chapter 28 for additional discussion of intimate partner violence and an example of an assessment screening tool.

Remember **Tammy Browning**, the young woman who is expecting her first child. The nurse would include an assessment of current and past use of alcohol and drugs as part of Tammy's admission to the birthing unit. This assessment would include questions regarding the type and amount of drugs and alcohol she has used or is using as well as the frequency of use.

Obtain information about the patient's mental health. "Mental health is an integral part of a patient's well-being; thus, the assessment of mental health status is essential" (Jensen, 2019, p. 185). Regular screenings in primary care and other health care settings enable earlier identification of mental health and substance use disorders, leading to earlier treatment and care. There are many assessment tools available to assist with screening for mental health disorders. Specific tools are available to screen for depression or suicide, for example, and to be used with specific populations, such as adolescents or older adults. The Patient Health Questionnaire-9 (PHQ-9), the most common screening tool to identify depression, is one example of a mental health assessment tool (Box 27-2 on page 782). Refer to Focused Assessment Guide 27-1 for examples of appropriate questions related to this component.

Sexual health is an essential element of overall health and well-being (Altarum Institute, 2019). Use neutral and inclusive terms (e.g., partner) and a nonjudgmental manner to obtain information about the patient's sexual history, sexual activity, gender identity, and sexual orientation. This information will help identify the needs of individual patients and provide patient-centered, culturally considerate care (Altarum Institute, 2019; Cahill et al., 2020). Box 27-3 (on page 782) provides some suggested strategies and essential health questions for assessment of sexual health. Additional points related to assessment of sexual and reproductive health are included in the "Assessing Female Genitalia" and "Assessing Male Genitalia" later in this chapter. Refer also to Chapter 46 for additional information.

Box 27-2	The Patient Health Questionnaire-9 (PHQ-9)

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Over the last 2 weeks, how often have you been bothered by any of the following problems? (Use "✓" to indicate your answer)	Not At All	Several Days	More Than Half the Days	Nearly Every Day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed, or hopeless	0	1	2	3
3. Trouble falling or staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself—or that you are a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed. Or the opposite—being so fidgety or restless that you have been moving around a lot more than usual.	0	1	2	3
9. Thoughts that you would be better off dead or of hurting yourself in some way	0	1	2	3
FOR OFFICE CODING 0 + _____ + _____ + _____ = Total Score: _____				

If you checked off any problems, how difficult have these problems made it for you to do your work, take care of things at home, or get along with other people?

Not difficult at all	Somewhat difficult	Very difficult	Extremely difficult
☐	☐	☐	☐

How to Score PHQ-9

Major Depressive Syndrome is suggested if:

- Of the 9 items, 5 or more are checked as at least "More than half the days"
- Either item #1 or #2 is positive, that is, at least "More than half the days"

Other Depressive Syndrome is suggested if:

- Of the 9 items, 2, 3, or 4 are checked as at least "More than half the days"
- Either item #1 or #2 is positive, that is, at least "More than half the days"

How to Score PHQ-9

Major Depressive Syndrome is suggested if:

- Of the 9 items, 5 or more are checked as at least "More than half the days"
- Either item #1 or #2 is positive, that is, at least "More than half the days"

Other Depressive Syndrome is suggested if:

- Of the 9 items, 2, 3, or 4 are checked as at least "More than half the days"
- Either item #1 or #2 is positive, that is, at least "More than half the days"

Box 27-3 **Strategies and Health Questions for Assessment of Sexual Health**

In a matter-of-fact manner, inform the patient that sexual health is important to overall health and these questions are asked of everyone.

Ask the patient's partner, relative, or caregiver to step out of the room for the assessment.

Give the patient the opportunity to ask questions or voice concerns.

Assure the patient that all information is confidential.

Ask the following questions in a nonjudgmental manner, using neutral and inclusive terms:

- Have you been sexually active in the last year? If yes, what types of sex do you have? With men, women, or both? How many partners have you had?
- If no, have you ever been sexually active?
- How do you think of yourself? Lesbian, gay, straight, bisexual; something else (specify); don't know
- What is your current gender identity? Male, female, female-to-male/transgender male/trans man, male-to-female/transgender female/trans woman, nonbinary or nonconforming, genderqueer, additional category

(specify), decline to answer
- What sex were you assigned at birth, as shown on your birth certificate? Male, female, decline to answer
- What are your pronouns? He/him, she/her, they/their, something else (specify)
- What do you do to protect yourself from STIs?
- Have you been vaccinated against HPV? Hepatitis A? Hepatitis B?
- What questions do you have about your body and/or sex?

Review of Systems

The review of systems is a series of questions about all body systems that helps to reveal concerns or problems as part of the health history. Many times, these questions can be incorporated into the physical examination of each region, such as asking about bowel habits when listening to bowel sounds in the abdomen. In addition, many questions relate to one or more body systems, thus the information obtained may pertain to more than one area. For example, asking about recent changes in weight is part of the overall health state, but it also provides information about fluid balance, and may offer information about appetite and functional ability. Examples of health history questions related to each body system are included in the discussion of each region of the physical examination later in the chapter.

PHYSICAL ASSESSMENT

Physical assessment is the systematic collection of objective information. The physical assessment is usually conducted in a head-to-toe sequence or a system sequence but can be adapted to meet the needs of the patient. It is often necessary to modify the sequence, positions, and specific assessments based on the patient's age, energy level, and cognitive and physical state, as well as time constraints. Even when modified, it is important to conduct the physical assessment in an organized and knowledgeable manner. Conducting an accurate physical assessment takes time and practice. Note that not all assessments included in a comprehensive physical assessment are covered in this chapter. The information reviewed here addresses the assessments that may be used by beginning and general health care providers. Consult an assessment textbook for additional information related to more advanced assessment procedures.

FIGURE 27-1. Equipment used in advanced assessment. **A.** Ophthalmoscope. **B.** Otoscope. **C.** Percussion hammer. **D.** Nasal speculum. **E.** Vaginal speculum and water-soluble lubricant. **F.** Tuning forks.

Preparing for a Physical Examination

Prior to beginning a physical examination, think about how to make the patient comfortable and relaxed. Be sure to use appropriate verbal and nonverbal communication techniques. Refer to the discussion earlier in this chapter. Think about the appropriate and essential components of the examination for the individual patient and circumstances, as well as the sequence of the examination—what order will be used to assess the areas required by the examination. Refer to the discussion of focused assessments earlier in the chapter.

Adjust the lighting and the environment; good lighting and a quiet environment are important, but not always possible. Do the best you can to make the conditions as favorable as possible (Hogan-Quigley et al., 2017). Refer also to the discussion of environmental preparation earlier in the chapter. Gather and check the equipment needed for the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

examination. Assist the patient to the appropriate position to start the examination. Use proper hand hygiene techniques and standard precautions when performing physical examinations. Transmission-based precautions are implemented in addition as needed. Refer to Chapter 25 for information about hand hygiene, standard precautions, and transmission-based precautions.

Equipment

The equipment used in a physical assessment should be readily accessible, clean, and in proper working order. Equipment that will touch the patient should be warmed (by the examiner's hands or warm water) before use. Following are details about the equipment most likely used by beginning health care providers. However, beginning health care providers may observe or assist with more advanced assessments. Refer to Figure 27-1 for equipment that may be used by more advanced health care providers. Nurses will need a watch with a second hand in addition to the materials identifies below. Clean equipment after use with each patient, based on facility policies, to prevent transmission of microorganisms between patients or between the patient and the nurse. Refer to the accompanying Research in Nursing display related to stethoscope hygiene.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Stethoscope Hygiene

Stethoscopes, like other patient care equipment, should be cleaned between patients and undergo routine disinfection to prevent the spread of microorganisms. This simple intervention is rarely done despite guideline recommendations (Holleck et al., 2020). What can be done to improve compliance by health care professionals?

Related Evidence

Holleck, J. L., Campbell, S., Alrawili, H., Frank, C., Merchant, N., Rodwin, B., Perez, M. F., Gupta, S., Federman, D. G., Chang, J. J., Vientos, W., & Dembry, L. (2020). Stethoscope hygiene: Using cultures and real-time feedback with bioluminescence-based adenosine triphosphate technology to change behavior. *American Journal of Infection Control*, *48*(4), 380–385. https://doi.org/10.1016/j.ajic.2019.10.005

The purpose of this quality improvement project was to determine whether demonstrating what is growing on the stethoscopes of providers via culture or bioluminescence technology alters perceptions and improves compliance with stethoscope hygiene. In addition, the researchers sought to gain a better understanding of the beliefs and the barriers to stethoscope hygiene. Participants included medical students, house staff, and attending physicians on the medical wards at a Department of Veterans Affairs (VA) tertiary care teaching hospital. Beginning with the first week of their medicine inpatient rotations at the VA, providers were given the opportunity to culture their stethoscopes and swab for bioluminescence-based adenosine triphosphate testing before and after disinfection with alcohol pads, alcohol-based hand rub, or hydrogen peroxide disinfectant wipes. Beginning with the second week of their rotations, actual photographic images of stethoscope culture plates before and after disinfection were presented for visual impact at a morning report. Bioluminescence scores of stethoscopes before and after disinfection were provided in real-time and again when presenting images of the stethoscope cultures. Pre-surveys exploring beliefs and barriers to stethoscope hygiene were administered initially prior to any intervention and post-surveys were administered 2 days after presentation of the results. Baseline observations of hand and stethoscope hygiene rates were discreetly recorded at the start of rotations, after presenting the culture images and bioluminescence scores during the second week and during the fourth week of provider rotations. The bacteria isolated, colony-forming units (CFUs), and bioluminescence scores were tracked. This 4-week period was repeated for a total of three cycles. A total of 1,245 observed hand hygiene opportunities showed that compliance improved from 72.5% to 82.3% ($p < .001$). Observed patient–provider encounters (590) revealed no significant change in stethoscope hygiene rates of 10% initially and 5% afterward ($p = .08$), although self-reported rates trended from 56% to 67% postintervention ($p = .06$). Perceptions regarding stethoscope hygiene importance improved 8.5/10 to 9.3/10; $p = .04$. Disinfection with alcohol pads, alcohol-based hand rub, and hydrogen peroxide disinfectant wipes were equivalent in CFU reduction ($p = .21$). The top three barriers to stethoscope hygiene were forgetfulness, time constraints, and limited access to supplies. The authors concluded that showing providers what is growing on their stethoscopes improved "buy in" regarding stethoscope hygiene importance. Objective observations failed to show improvement in stethoscope hygiene rates, but hand hygiene performance improved. The authors noted a significant gap between what providers think they are doing and what they are actually doing.

Relevance to Nursing Practice

Disinfection of patient care equipment, such as stethoscopes, reduces bacteria on the equipment, including the potential to reduce and limit transmission of pathogens. Stethoscopes, like other patient care equipment, should be cleaned between patients and undergo routine disinfection. Nurses and other health care providers need to be aware of the potential barriers to implementation and make a conscious effort to implement equipment hygiene as part of

patient care. Facilities must ensure adequate access to disinfection supplies and consider interventions to support use of disinfectants to reduce barriers to implementation.

THERMOMETER AND ELECTRONIC OSCILLOMETRIC BLOOD PRESSURE DEVICE OR SPHYGMOMANOMETER

The thermometer is used to measure the patient's body temperature. Use of an electronic oscillometric device is used to measure blood pressure and is preferred over the auscultatory method of measurement (Muntner et al., 2019). A sphygmomanometer is required to complete an auscultatory measurement of blood pressure. Refer to Chapter 26 for a more detailed discussion of equipment to measure vital signs.

SCALE

A scale (Fig. 27-2) with height attachment is used to weigh the patient and measure height. Chair scales are available for patients who are unable to stand. Infants and children younger than age 2 or 3 years are weighed on a platform-type balance scale (Jarvis & Eckhardt, 2020). Beds for use in hospitals and other facilities may have a scale built into the bed. Height may also be measured using a stadiometer, a device for measuring height that consists of a vertical ruler with a sliding horizontal rod or paddle, which is adjusted to rest on the top of the head. It is often wall mounted but is used horizontally on a tabletop for infants and young children to measure length.

FIGURE 27-2. A scale with height attachment is used to weigh the patient and measure height. (*Source:* Jensen, S. [2019]. Nursing health assessment: A best practice approach [3rd ed.]. Wolters Kluwer Health.)

FLASHLIGHT OR PENLIGHT

A light source is used to assist in viewing inside the mouth and nose. It is also used to determine the reactions of the pupils of the eyes.

STETHOSCOPE

The stethoscope, illustrated and described in Chapter 26, is used to measure blood pressure. It is also used to auscultate (listen to) heart, lung, abdomen, and cardiovascular sounds (Fig. 27-3). When using the stethoscope, expose the body part to be auscultated and try to minimize environmental noises. Use the *bell* of the stethoscope to detect low-pitched sounds. Hold the bell lightly against the body part being auscultated. Use the *diaphragm* of the stethoscope to detect high-pitched sounds (such as normal heart sounds, breath sounds, and bowel sounds). Hold the diaphragm firmly against the body part being auscultated.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 27-3. Stethoscope bell and diaphragm.

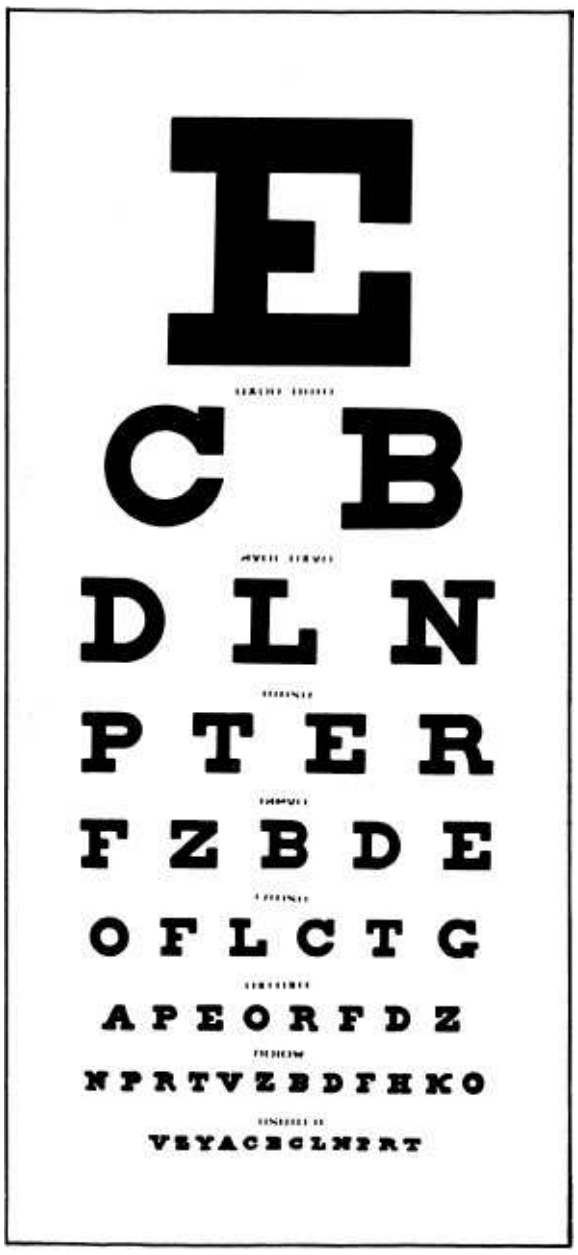

FIGURE 27-4. Snellen chart.

METRIC TAPE MEASURE AND RULER

A tape measure is used to measure waist circumference in adults. It is also used to measure head circumference in infants and children, as well as chest circumference in infants. A ruler is used to measure abnormal findings on the skin, such as wounds, incisions, or lesions.

EYE CHART

A Snellen eye chart (Fig. 27-4), or other vision assessment tool, is used to screen for distant vision. The Snellen chart consists of characters arranged in lines of different-sized type; the line of largest characters is at the top of the chart and the line of smallest characters is at the bottom. Scores ranging from 20/10 (the smallest line of characters) to 20/200 (the largest line of characters) indicate visual acuity.

A handheld vision screener, such as a Jaeger card, can be used to test near vision. The Jaeger card also consists of characters arranged in lines of different-sized type, like the Snellen chart. A distance equivalent based on the Snellen chart is shown on the side of the card.

Positioning and Draping

A variety of positions may be used during a physical assessment (see Box 27-4 on page 786). During positioning, it is important to consider the patient's age, culture, health status, mobility, physical condition, energy level, and privacy.

Positioning patients who are weak or have physical limitations may require assistance. Position should be adjusted to accommodate patient limitations, such as arthritis, confusion, pain, or respiratory problems. Uncomfortable or embarrassing positions should not be maintained for long periods. The assessment should be organized so that several body systems can be assessed with the patient in one position, thus minimizing unneeded and possibly tiring movements.

Box 27-4 **Positions Used During Physical Assessment**

Standing

The patient stands erect. This position should not be used for patients who are weak, dizzy, or prone to fall. It is used to assess posture, balance, and gait (while walking upright).

Standing

Supine

The patient lies flat on the back with legs extended and knees slightly flexed. It facilitates abdominal muscle relaxation and is used to assess vital signs and the head, neck, anterior thorax, lungs, heart, breasts, abdomen, extremities, and peripheral pulses.

Supine

Sims Position

The patient lies on either side with the lower arm below the body and the upper arm flexed at the shoulder and elbow. Both knees are flexed, with the upper leg more acutely flexed. It is used to assess the rectum or vagina.

Sims position

Lithotomy

The patient is in the dorsal recumbent position with the buttocks at the edge of the examining table and the heels in stirrups. It is used to assess female genitalia and rectum.

Lithotomy

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sitting

The patient may sit in a chair or on the side of the bed or examining table, or remain in bed with the head elevated. It allows visualization of the upper body, facilitates full lung expansion, and is used to assess vital signs and the head, neck, anterior and posterior thorax, lungs, heart, breasts, and upper extremities.

Sitting

Dorsal Recumbent

The patient lies on the back with legs separated, knees flexed, and soles of the feet on the bed. It is used to assess the head, neck, anterior thorax, lungs, heart, breasts, extremities, and peripheral pulses. It should not be used for abdominal assessment because it causes contraction of the abdominal muscles.

Dorsal recumbent

Prone

The patient lies flat on the abdomen with the head turned to one side. It is used to assess the hip joint and the posterior thorax.

Prone

Knee–Chest

The patient kneels, with the body at a 90-degree angle to the hips, back straight, arms above the head. It is used to assess the anus and rectum.

Knee-chest

Draping prevents unnecessary exposure, provides privacy, and keeps the patient warm during the physical assessment. Drapes may be paper, cloth, or bed linens. When conducting an assessment, expose only the body parts being assessed to maintain the patient's modesty and comfort.

Techniques of Physical Assessment

The four primary assessment techniques are inspection, palpation, percussion, and auscultation. These techniques are

most often used in the sequence listed; variations are noted in the discussion of specific body areas later in the chapter. Bilateral body parts are always compared; for example, the assessment findings of one leg are compared with those of the other leg. Bilateral body parts are normally symmetric; that is, they have the same size and shape as well as the same characteristics, such as movement or pulses. Wait until the end of the examination to assess any areas that are likely to be painful or cause the patient extreme discomfort.

Inspection

Inspection is the process of performing deliberate, purposeful observations in a systematic manner. Closely observe visually but also use hearing and smell to gather data throughout the assessment. Assess details of the patient's appearance, behavior, and movement. Inspection begins with the initial patient contact and continues through the entire assessment. Adequate natural or artificial lighting is essential for distinguishing the color, texture, and moisture of body surfaces.

Inspect each area of the body for size, color, shape, position, movement, and symmetry, noting normal findings and any deviations from normal. Inspection is usually followed by palpation during the assessment of each body part.

Palpation

Palpation uses the sense of touch. The hands and fingers are sensitive tools that can assess skin temperature, turgor, texture, and moisture, as well as vibrations within the body (such as the heart) and shape or structures within the body (e.g., the bones). Specific parts of the hand are more effective at assessing different qualities (Fig. 27-5). The dorsum (back) surfaces of the hand and fingers are used for gross measure of temperature. The palmar (front) surfaces of the fingers and fingerpads are used to assess firmness, contour, shape, tenderness, and consistency. The fingerpads are best at fine discrimination. Use fingerpads to locate pulses, lymph nodes, and other small lumps, and to assess skin texture and edema. Vibration is palpated best with the ulnar, or outside, surface of the hand.

The nurse's hands should be warmed and the fingernails short. Prior to any assessment involving palpation, inform the patient about the areas to be palpated and ask for permission to use touch. When conducting palpation, any area of tenderness is palpated last. Light or deep palpation may be used, controlling the depth by the amount of pressure applied. For light palpation, apply pressure with the fingers together and lightly depressing the skin and underlying structures about 1 to 2 cm (0.5 inch to 0.75 inch) (Fig. 27-6). Light palpation is used to feel for pulses, tenderness, surface skin texture, temperature, moisture, and muscular resistance (Jarvis & Eckhardt, 2020; Jensen, 2019; Weber & Kelley, 2018). Deep palpation is used to assess organs, masses, structures that are covered by thick muscle and tenderness (Jensen, 2019; Weber & Kelley, 2018). Deep palpation should be used cautiously and only by experienced advanced health care providers. Refer to a health assessment text for details of this advanced physical assessment skill.

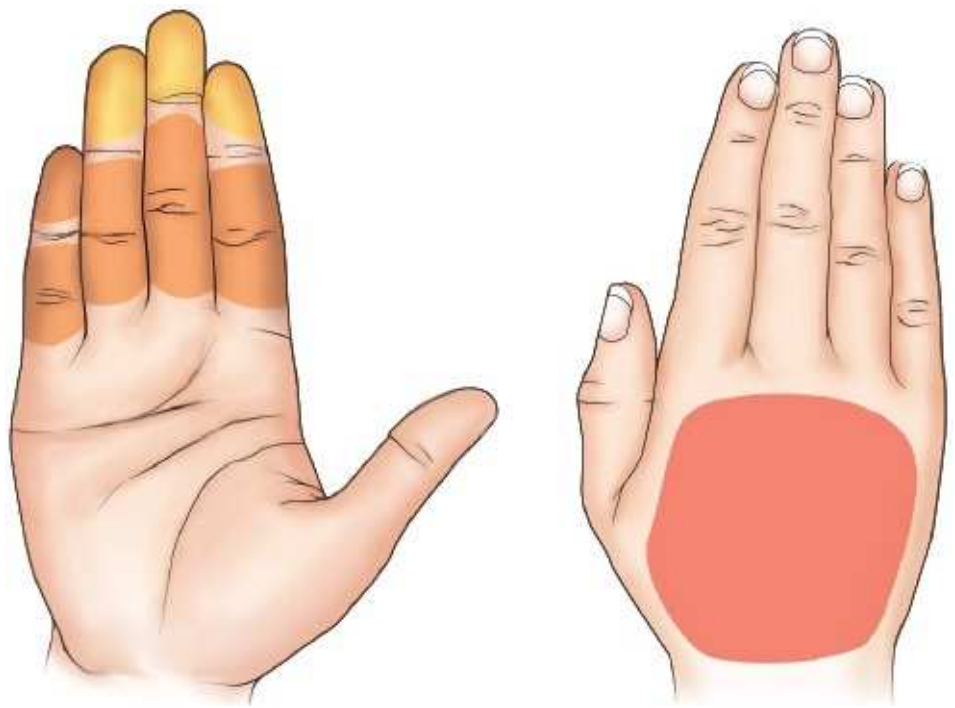

FIGURE 27-5. (**Left**) Palmar surfaces of the examiner's fingertips and fingerpads are used for discriminatory sensation such as firmness, tenderness, and shape. (**Right**) The dorsum, or back of the hand, is used to assess surface temperature. Fingers and fingerpads are used to assess firmness, contour, shape, tenderness, and consistency.

Percussion

Percussion is the act of striking one object against another to produce sound. The fingertips are used to tap the body over body tissues to produce vibrations and sound waves. The characteristics of the sounds produced are used to assess the location, shape, size, and density of tissues. Abnormal sounds suggest alteration of tissues or the presence of a mass. Percussion is an advanced physical assessment skill, usually performed by advanced practice professionals. Refer to a health assessment text for details.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 27-6. In light palpation, light pressure is applied by placing the fingers together and depressing the skin and underlying structures about 1 to 2 cm (0.5 inch to 0.75 inch). (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

Auscultation

Auscultation is the act of listening with a stethoscope to sounds produced within the body. Auscultation is performed by placing the stethoscope diaphragm or bell against the body part being assessed. When auscultating, expose the part listened to, use the proper part of the stethoscope (diaphragm or bell) for specific sounds (see previous discussion of a stethoscope), and listen in a quiet environment. The characteristics of sound assessed by auscultation include pitch (ranging from high to low), loudness (ranging from soft to loud), quality (e.g., gurgling or swishing), and duration (short, medium, or long).

Conducting a Physical Assessment

There are various organizing structures for conducting a physical assessment. Health care providers often proceed in a head-to-toe, body system approach, including all or some of the assessments, based on the circumstances and needs for an individual patient. Think about the appropriate and essential components of the examination for the individual patient and circumstances, as well as the sequence of the examination. Refer to the discussion of focused assessments on page 780. Although each body system is discussed individually here, in reality, nurses usually combine several systems (e.g., while assessing the head and neck they also assess the cranial nerves, which are part of the neurologic system). As identified earlier in the discussion of the review of systems, questions about a body system are often incorporated into the physical examination of each region. Examples of health history questions related to each body system are included in the discussion of each region of the physical examination later in the chapter. The accompanying head-to-toe assessment video demonstrates one potential sequence as well as proper technique.

Performing a General Survey

The general survey contributes to an overall impression of the patient. It includes observing the patient's overall appearance and behavior, taking vital signs, measuring height, weight, and waist circumference, head circumference (infants and children up to age 2 years [American Academy of Pediatrics, 2020; Weber & Kelley, 2018]), and calculating the body mass index (BMI). Information obtained from the general survey provides clues to the patient's overall health.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of changes in weight
- History of pain or discomfort
- Sleeping patterns, difficulty sleeping

APPEARANCE AND BEHAVIOR

Observation of the patient's appearance and behavior provides information about various aspects of the patient's health. While collecting information during the health history, inspect the patient's body build, posture, and gait. Note proportion of height to weight, which provides insight into nutritional status. Observe whether the patient has an erect or slumped posture, and evaluate movements and gait pattern for coordination. Uncoordinated or spontaneous movements may suggest neurologic problems. Note signs of illness and/or distress, such as changes in posture, skin color, and respirations; nonverbal communication of pain; and a short attention span.

Observe hygiene and grooming (cleanliness, body odors) and note any deficits, which may indicate other problems. For example, patients with inappropriate dress (e.g., wrong for the season) or worn or dirty clothing may be experiencing feelings of depression or have inadequate financial resources. Assess cognitive processes (speech content and patterns; orientation to person, place, and time; appropriate verbal responses). As cognitive processes are controlled by the neurologic system, these are discussed later in the chapter.

Clues to mood and mental health are provided by speech, facial expressions, ability to relax, eye contact, and behavior. If depression, anxiety, or other mental health disorders are suspected, use appropriate screening tools and refer

the patient to the appropriate health care professionals as necessary. The PHQ-9, a common screening tool to identify depression, was mentioned earlier in the chapter in the discussion of psychosocial and lifestyle factors (Box 27-2 on page 782). Box 27-5 presents the Geriatric Depression Scale, a useful tool in screening older adults for depression. This tool is completed by the patient and reviewed by the health care provider.

HEIGHT AND WEIGHT

The ratio of height to weight is an assessment of overall health and potential overnutrition or undernutrition. Measure height and weight using accurate scales and measuring devices. Ask the patient to remove shoes and heavy clothing if the measurements are taken before undressing (Guidelines for Nursing Care 27-1). If the patient cannot stand erect, obtain weight using a chair or bed scale. Refer to Skill 27-1 (on pp. 822–824) for instructions to obtain a patient's weight using a portable bed scale. Make sure to measure the height (length) of children age 2 years and younger in the recumbent position with the legs fully extended (Jarvis & Eckhardt, 2020). Weigh infants without any clothing, and weigh children in their underwear.

Remember **Ramona Lewis**, the young woman with anorexia nervosa. The nurse would use baseline data, including Ramona's height and weight, to monitor Ramona's health status.

HEAD CIRCUMFERENCE

Head circumference is measured at birth and each physical examination for infants and children up to age 2 years (American Academy of Pediatrics, 2020; Weber & Kelley, 2018). Circle the tape measure around the infant or child's head (not including the ears), beginning at the forehead just above the eyebrows, bringing the tape around the head just above the occipital prominence at the back of the head, using the widest span (Jarvis & Eckhardt, 2020; Kyle & Carmen, 2021). Measurements are used to show the pattern of head growth.

Box 27-5 **Geriatric Depression Scale (GDS)**

BODY MASS INDEX AND WAIST CIRCUMFERENCE

BMI (adults and children) and waist circumference (adults) are the preferred methods to establish ideal body weight (National Heart, Lung, and Blood Institute, n.d.a). **Body mass index (BMI)** is a ratio of weight to height. BMI is used as an initial assessment of nutritional status and is an indicator of obesity or malnutrition. BMI also provides an estimation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of relative risk for some diseases, such as heart disease, high blood pressure, type 2 diabetes, gallstones, breathing problems, and certain cancers (National Heart, Lung, and Blood Institute, n.d.a). Calculate the BMI after obtaining the patient's height and weight. Refer to the discussion of BMI, including method for calculation, in Chapter 37.

Guidelines for Nursing Care 27-1

Obtaining Height and Weight With an Upright Balance Scale

Obtaining Height

- Ask the patient to remove shoes.
- Raise L-shaped sliding arm on the measuring device attached to the scale somewhat higher than the patient's approximate height.
- Ask the patient to step on the platform of the scale and stand erect with the back to the measuring device and the heels together.
- Lower the L-shaped sliding arm until it rests on top of the patient's head.
- Read the height in inches and record.
- Ask the patient to step down from the platform.

Obtaining Weight

- Balance the scale on "zero."
- Ask the patient to remove shoes (and coat, if appropriate) and step onto the platform.
- Move the sliding indicator to the left until the scale balances.
- Read the weight in pounds and record.
- Ask the patient to step down from the platform.
- Return the scale weight indicator to zero.
- Considerations: Daily weights should be obtained at the same time each day (usually early morning), with the patient wearing the same clothing, and using the same scale.

Source: Used with permission from Shutterstock. *Photo by B. Proud.*

Waist circumference is the measurement around a patient at the level of the umbilicus and is a good indicator of abdominal fat. The location of excess body fat is thought to be an important and reliable indicator of risk for diseases. Refer to the discussion of waist circumference in Chapter 37.

VITAL SIGNS

Vital signs are measured to establish a baseline for the database and to detect actual or potential health problems. Some facilities, particularly acute care facilities, may include measurement of oxygen saturation as part of the vital signs. Vital

signs are discussed in detail in Chapter 26. Oxygen saturation is discussed in Chapter 40.

PAIN

Pain assessment is often considered the fifth vital sign. Assessment of pain is part of the initial assessment of a patient and continues throughout the nurse–patient relationship. Assessment of pain is discussed in Chapter 36.

Assessing the Integument

The integument is comprised of the skin, nails, hair, scalp and sweat and sebaceous glands. Assessing the integumentary structures provides information about the patient's overall health status, as well as clues to local or systemic health problems. It also provides data about self-care activities to maintain health, hygiene, and nutrition. Assessing for skin cancer is essential and provides the base for teaching skin cancer prevention. Refer to Box 27-6 for guidelines on assessing for melanoma. Additional information related to assessment of the integument is discussed in Chapter 33.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of rashes, lesions, change in color, or itching
- History of bruising or bleeding in the skin
- History of allergies to medications, plants, foods, or other substances
- Exposure to the sun and sunburn history
- History of bathing routines and products
- Presence of lesions (wounds, bruises, abrasions, or burns)
- Presence of body piercings and/or tattoos
- Change in the color, size, or shape of a mole
- Exposure to chemicals that may be harmful to the skin, hair, or nails
- Degree of mobility
- Types of food eaten and liquids consumed each day
- Cultural practices related to skin

PHYSICAL ASSESSMENT

The skin, hair, and nails are assessed by inspection and palpation. Assessment of the skin should begin with the general survey and continue throughout the physical examination. Protect the patient's privacy by exposing only the body part being examined. If the patient has lesions of the skin (including the scalp) or an infestation of the hair with lice, wear gloves during palpation.

Box 27-6 Assessing for Melanoma

Warning Signs: The ABCDEs of Melanoma

A: Asymmetry

If a line is drawn through a mole, the two halves will not match.

B: Border

The borders of an early melanoma tend to be uneven. The edges may be scalloped or notched.

C: Color

Having a variety of colors is another warning signal. A number of different shades of brown, tan, or black could appear. A melanoma may also become red, white, or blue.

D: Diameter

Melanomas usually are larger in diameter than the size of the eraser on your pencil (1/4 inch or 6 mm), but they may sometimes be smaller when first detected.

E: Evolving

Any change—in size, shape, color, elevation, or another trait, or any new symptom such as bleeding, itching, or crusting—points to danger.

Source: Skin Cancer Foundation. (2019). Melanoma overview. https://www.skincancer.org/skin-cancer-information/melanoma/ Copyright The Skin Cancer Foundation All Rights Reserved. For more information on skin cancer visit SkinCancer.org.

The skin is a general indicator of the patient's health status and provides information that might indicate an underlying disease. Begin the assessment with an overall inspection of the skin's condition. Assess specific areas of the skin during assessment of other body systems (e.g., you may assess the skin on the abdomen while performing other

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

abdominal assessments). Ensure adequate lighting, which is essential for accurate assessments. Inspect the skin for color, vascularity, and lesions (Fig. 27-7), and palpate for temperature, moisture, turgor, and texture.

FIGURE 27-7. The skin is inspected for color, vascularity, and lesions. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

Table 27-1 Skin Color Assessment

COLOR VARIATIONS	ASSESSMENT AREAS	POSSIBLE CAUSES
Redness (erythema, flushing)	Facial area, localized area of skin on the body	Blushing, alcohol intake, fever, injury trauma, infection
Bluish (cyanosis)	Exposed areas, particularly the ears, lips, inside of the mouth, hands and feet, and nail beds	Cold environment, cardiac or respiratory disease (decreased oxygenation)
Yellowish (jaundice)	Overall skin areas, mucous membranes, and sclera	Liver disease (increase in bilirubin levels)
Paleness (pallor)	Exposed areas, particularly the face and lips, conjunctivae, and mucous membranes	Anemia (decreased hemoglobin)
	Shock (decreased blood volume)	
Vitiligo (whitish patchy areas on the skin)	Overall skin areas, lips, nail beds, and conjunctivae	Depigmentation (congenital or autoimmune conditions)
Tanned or brown	Sun-exposed areas	Overexposure (increased melanin production), pregnancy (brown spots)

Inspecting Skin Color

Skin color varies among races and among people, ranging from a pinkish white to various shades of brown. Skin areas that are normally exposed, such as the face and hands, may have a somewhat different color from areas that are usually covered by clothing, but otherwise skin color is relatively consistent. Some body areas of people with darker skin tones, such as the palms of the hands and the soles of the feet, normally have less pigmentation than other body areas.

Changes in skin color include erythema, cyanosis, jaundice, and pallor (Table 27-1). These color changes are often easier to assess in people with light skin tones. **Erythema**, redness of the skin, is caused by dilation of superficial blood vessels. It is associated with sunburn, inflammation, fever, trauma, and allergic reactions. When assessing for erythema in people with darker skin tones, it is important to assess skin temperature; areas of erythema will feel warm when compared with surrounding skin.

Think back to **Billy Collins**, the child who was stung by a bee. The nurse would use inspection skills to observe for erythema in the area of the sting.

Cyanosis is a bluish or grayish discoloration of the skin in response to inadequate oxygenation. Cyanosis is assessed as a blue tinge in patients with lighter skin and as dullness in patients with dark skin tones. **Jaundice** is a yellow color of the skin resulting from elevated amounts of bilirubin in the blood. It is associated with liver and gallbladder disease, some types of anemia, and excessive hemolysis (breakdown of red blood cells). It usually develops first in the sclera of the eyes and then in the skin and mucous membranes. It is more difficult to observe jaundice on the trunk of the body in patients with darker skin tones, but the sclera, oral mucous membranes, palms, and soles appear yellow to yellow-orange. **Pallor**, or paleness of the skin, often results from a decrease in the amount of circulating blood or hemoglobin, causing inadequate oxygenation of the body tissues. Depending on severity, pallor may be visible over the entire skin surface or only in the lips, nail beds, mucous membranes, and conjunctiva. Pallor in patients with dark skin tones is seen as an ashen gray or yellow tinge.

Inspecting Skin Vascularity and Lesions

Inspect the skin for vascularity, bleeding, or bruising; these signs might relate to a cardiovascular, hematologic, or liver dysfunction. **Ecchymosis** is a collection of blood in the subcutaneous tissues, causing purplish discoloration. **Petechiae** are small hemorrhagic spots caused by capillary bleeding. If they are present, assess their location, color, and size.

Lesions are areas of diseased or injured tissue such as bruises, scratches, cuts, burns, insect bites, and wounds (breaks in the continuity of the skin). Assess lesions and wounds for size, shape, depth, location, and presence of drainage or odor. Refer to a health assessment text for details of terms used to describe different types of lesions. Wounds are discussed in Chapter 33. Scars are healed wounds. Describe rashes (skin eruptions) in terms of their type, size, elevation, coloring, and presence of drainage or itching. Assess the location and condition of body piercings and/or tattoos. Document the exact body surface areas involved.

Palpating Skin Temperature, Texture, Moisture, and Turgor

The skin is normally warm and dry. An increase in skin temperature and moisture can indicate an elevated body temperature. The texture of the skin varies from smooth and soft to rough and dry. In the dehydrated patient, the texture is dry, loose, and wrinkled, and the mucous membranes are cracked and dry. An excessive amount of perspiration, such as when the entire skin is moist, is called **diaphoresis**.

Turgor is the fullness or elasticity of the skin. It is usually assessed on the sternum or under the clavicle by lifting a fold of skin with the thumb and first finger (Fig. 27-8 on page 792). Skin turgor is considered normal when the fold returns to its usual shape when released. When the patient is dehydrated, the skin's elasticity is decreased, and the skin fold returns slowly. Decreased skin turgor may be a normal finding in older adults as a result of decreased elasticity and thinning of the dermis as a person ages.

FIGURE 27-8. To assess skin turgor, a small fold of skin is picked up and then released to return to its normal shape. Difficulty in lifting a skin fold may indicate presence of edema. (*Source:* Used with permission from Shutterstock. *Photo by B. Proud.*)

Difficulty in lifting a skin fold may indicate **edema** (excess fluid in the tissues). Edema is characterized by swelling,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

with taut and shiny skin over the edematous area. If the area of edema is palpated with the fingers, an indentation (measured in millimeters for depth of the indentation) may remain after the pressure is released; if the indentation is very deep, it is called pitting edema. Edema may be graded; refer to Chapter 41 for a visual representation of a grading system (p. 1680). Edema may be the result of overhydration, heart failure, kidney failure, trauma, or peripheral vascular disease.

Inspecting the Nails

Inspect the nails for shape, angle, texture, and color. The nails should be somewhat convex and should follow the natural curve of the finger. The angle between the nail and its base should be about 160 degrees. The nails should be smooth, and the nail base, when palpated, should be firm and nontender. Abnormal findings include infection, painless separation of the nail plate from the nail, increased brittleness or thickness, and clubbing (bulging of the last part of the finger with curved, convex nails related to reduced oxygen in the blood).

Inspecting the Hair and Scalp

Hair may be found on all body surfaces except the palms of the hands, the soles of the feet, and parts of the genitalia. Assess the hair for color, texture, and distribution. The hair is normally resilient, evenly distributed, and neither excessively dry nor oily. Abnormal findings include unusual balding (alopecia) and excessive amounts of hair on the face and body (hirsutism). Hair loss may be normal or may be the result of chemotherapy, radiation therapy, infection, hormonal disorders, or inadequate nutrition. Decreased oxygenation of peripheral tissues, especially of the lower extremities, may cause loss of hair. Excessive hair growth may occur in people with hormonal disorders.

Separate the hair to inspect the scalp for color, dryness, scaliness, lumps, lesions, or lice. Nits, which are the white eggs of lice, can be differentiated from dandruff or lint because they are attached to the hair shaft. If lumps or masses are palpated, note their location, size, tenderness, and mobility.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common skin variations in newborns and children include:

- Jaundice and milia (whiteheads) in newborns
- Fine downy hair (lanugo) for the first 2 weeks of life
- Smooth, thin skin at birth
- Pubic hair development at the onset of puberty

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common skin variations in the older adult include:

- Wrinkles, dryness, scaling, decreased turgor
- Raised dark areas (senile keratosis)
- Flat, brown age spots (senile lentigines)
- Small, round red spots (cherry angioma)
- Fine, brittle gray or white hair
- Hair loss
- Coarse facial hair in women, decreased body hair in men and women
- Thick, yellow toenails

Assessing the Head and Neck

Assessment of the head and neck includes the skull, face, eyes, ears, nose and sinuses, mouth and pharynx, trachea, thyroid gland, and lymph nodes. During the health history, note any health problems such as headaches or dizziness. If the patient smokes, include a discussion about ways to stop smoking in the care plan. Physical examination of the structures of the head and neck provides data about the shape and structure of cranial bones, function of special senses (sight, hearing, taste, smell), nasal and oral structures, and any swelling or pain in the lymph nodes in the neck. Assessment of the size and consistency of the thyroid gland is performed by advanced practice professionals. Refer to a health assessment text for details.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- Changes in vision or hearing with aging
- History of use of corrective lenses or hearing aids
- History of allergies
- History of disturbances in vision or hearing
- History of chronic illnesses such as hypertension, diabetes mellitus, or thyroid disease
- Exposure to harmful substances or loud noises
- History of smoking (how long, how many packs/day), chewing tobacco, or cocaine use
- Presence of body piercings and/or tattoos
- History of eye or ear infections

- History of head trauma
- Oral and dental care practices

PHYSICAL ASSESSMENT

Inspecting and Palpating the Head and Face

Inspect and palpate the head for size and shape. The parts of the head and face should be in proportion to each other and symmetric. Although the shape of the normal skull varies considerably, generally the shape is gently curved with prominences at the frontal and parietal bones. Abnormal findings include lack of symmetry or unusual size or contour of the skull (either may be the result of trauma or diseases affecting the growth of bone) and tenderness. If the skull of a child or an adult appears disproportionately large or small, measure the circumference. Measuring head circumference is a normal part of infant assessment to the age of 2 years and should be conducted at each health-related visit.

Inspect the face for color, symmetry, and distribution of facial hair. Edema of the face, especially around the eye (periorbital edema), and involuntary facial movements (e.g., tics, tremors) are abnormal findings. If abnormalities are noted, document the location, amount, duration, and timing.

Inspecting the Eyes

Assess the structures and functions of the eyes using a penlight and an eye chart. Inspection is the primary assessment technique used. Assessment includes the external eye structures, visual acuity, extraocular movements, and peripheral vision. Advanced health care providers usually perform assessment of the internal eye structures with an ophthalmoscope, which is an advanced assessment skill. Refer to a health assessment text for details.

Inspecting External Eye Structures. Inspect the eyes, eyebrows, eyelids, eyelashes, lacrimal glands, pupils, and iris for position and alignment (Fig. 27-9). Asymmetry of position and alignment of the eyes may be caused by muscle weakness or a congenital abnormality. The eyebrows should be equally distributed; the eyelashes should curl outward.

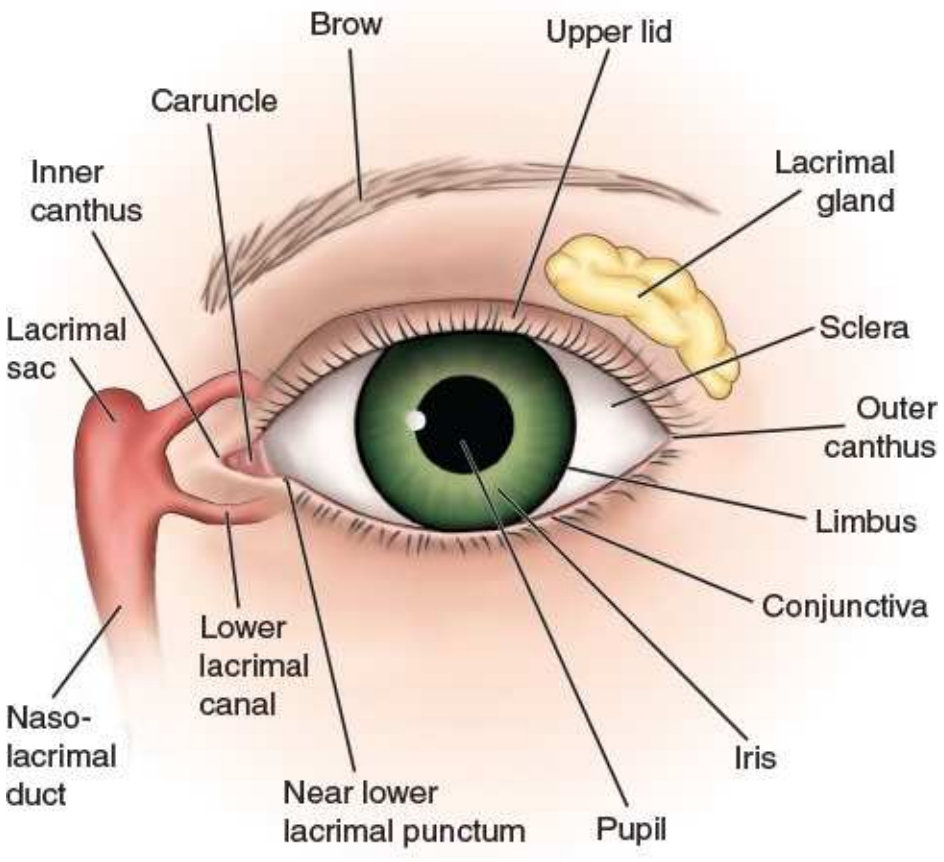

FIGURE 27-9. The eye and surrounding structures.

Inspect the eyelids for color, edema, and equal coverage of the eyeball. Abnormal findings include drooping of the upper lids (ptosis), which may be attributable to damage to the oculomotor nerve, myasthenia gravis, or a congenital disorder; inward turning of the lower lid and lashes (entropion); outward turning of the lower lid and lashes (ectropion); and redness or drainage (from infection of the lid margins, conjunctivae, or hair follicles). Inspect and palpate the lacrimal glands for edema and pain.

The pupils are normally black, equal in size, round, and smooth. The pupils may be pale and cloudy if the patient has cataracts (loss of opacity of the lens). Injury to the eye, glaucoma, and certain medications may cause the pupil to dilate (mydriasis); certain drugs can cause constriction (miosis), and unequal pupils may result from central nervous system injury or illness.

Assess the pupils for reaction to light and accommodation and for convergence (Guidelines for Nursing Care 27-2 on page 794). Decreased or absent pupillary response indicates blindness or serious brain damage. Inability of the eyes to accommodate or converge is abnormal.

Assessing Visual Acuity, Extraocular Movements, and Peripheral Vision. Assess visual acuity with the Snellen chart. Have the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

patient stand 20 ft from the chart and ask the patient to read the smallest line of letters possible, first with both eyes and then with one eye at a time (with the opposite eye covered). Note whether the patient's vision is being tested with or without corrective lenses.

Visual acuity is measured by using the standardized numbers listed on the side of the chart. The numerator is 20, representing the distance in feet the patient was from the test. The denominator represents the smallest line read accurately by the patient. Visual acuity is recorded as a fraction and is written as 20 over the smallest line read by the patient with no more than two inaccurate readings (such as "20/30–2 with glasses"). Thus, the larger the denominator, the poorer the patient's vision (Jensen, 2019). Use a Snellen picture chart or Snellen E-chart to test vision in patients who are unable to read English and in young children. The E-chart uses the capital letter E in varying sizes pointing in different directions. The patient points their fingers in the direction the legs of the E are pointing.

Test near vision with a handheld vision screen with varying sizes of print. A Jaeger card can be used for this measurement. The patient holds the card 14 inches from the eyes. Ask the patient to read the smallest line of letters possible, with one eye at a time (with the opposite eye covered), and corrective lenses in place, if used. The results are recorded as a fraction and written as 14 over the smallest line read by the patient. A normal result is 14/14.

Test extraocular movements by assessing the cardinal fields of vision for coordination and alignment. Normally both eyes move together, are coordinated, and are parallel. Tests for peripheral vision (or visual fields) are used to assess retinal function and optic nerve function. Full peripheral vision is normal. Guidelines for Nursing Care 27-3 describes how to assess extraocular movements and peripheral vision.

Guidelines for Nursing Care 27-2

Measuring Pupillary Reaction, Size, Accommodation, and Convergence

Pupillary Reaction

- Darken the room.
- Ask the patient to look straight ahead.
- Bring the penlight from the side of the patient's face and briefly shine the light on the pupil (Figure A).
- Observe the pupil's reaction; it normally rapidly constricts (direct response). Also observe pupil size (Figure B).
- Repeat the procedure and observe the other eye; it too normally will constrict (consensual reflex).
- Repeat the procedure with the other eye.

FIGURE A. Assessing pupillary reaction.

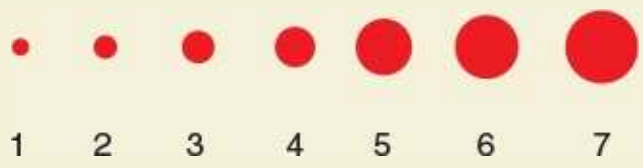

FIGURE B. Pupillary gauge measures pupils (dilation or constriction) in millimeters (mm).

Accommodation

- Hold the forefinger, a pencil, or other straight object about 10 to 15 cm (4 to 6 inches) from the bridge of the patient's nose.
- Ask the patient to first look at the object, then at a distant object, then back to the object being held. The pupil normally constricts when looking at a near object and dilates when looking at a distant object (Figure C).

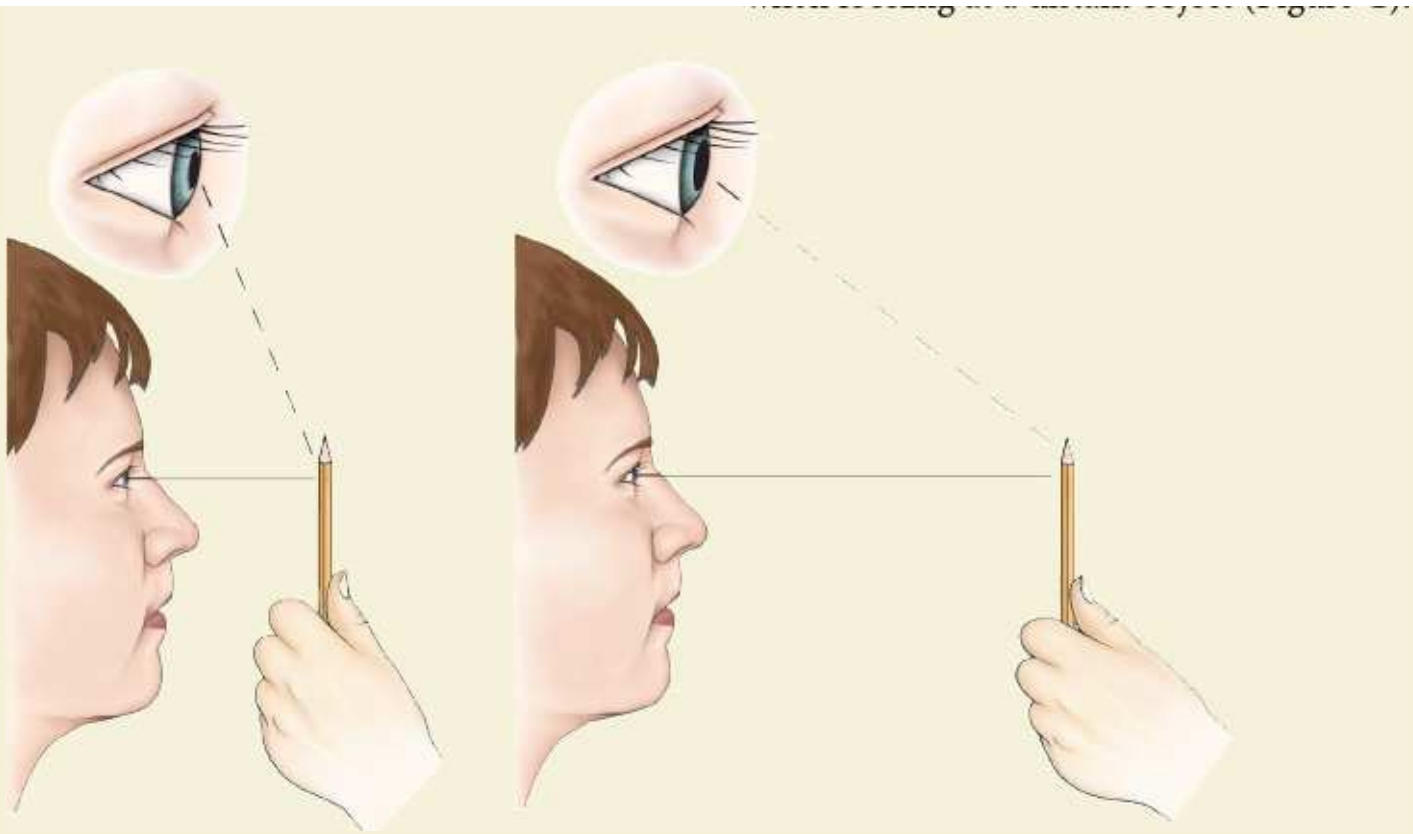

FIGURE C. Assessing accommodation.

Convergence

- Hold your finger about 6 to 8 inches from the bridge of the patient's nose.
- Move your finger toward the patient's nose to assess convergence (Figure D). The patient's eyes should normally converge (assume a cross-eyed appearance).

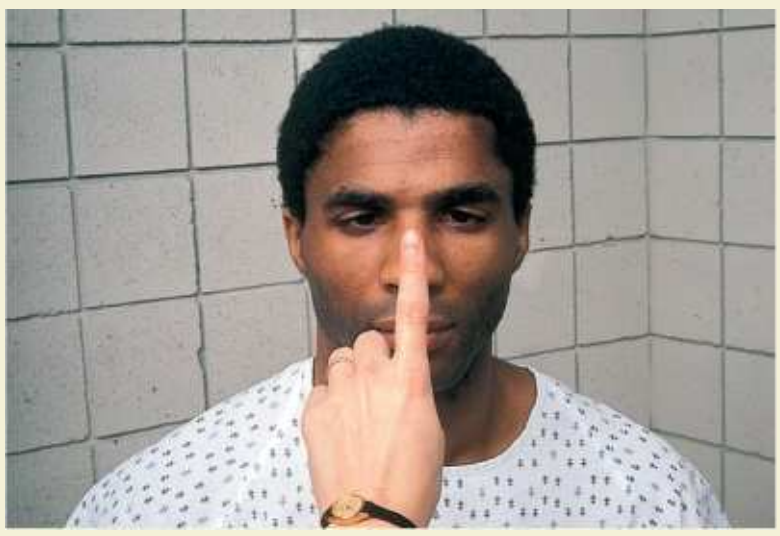

FIGURE D. Assessing convergence.

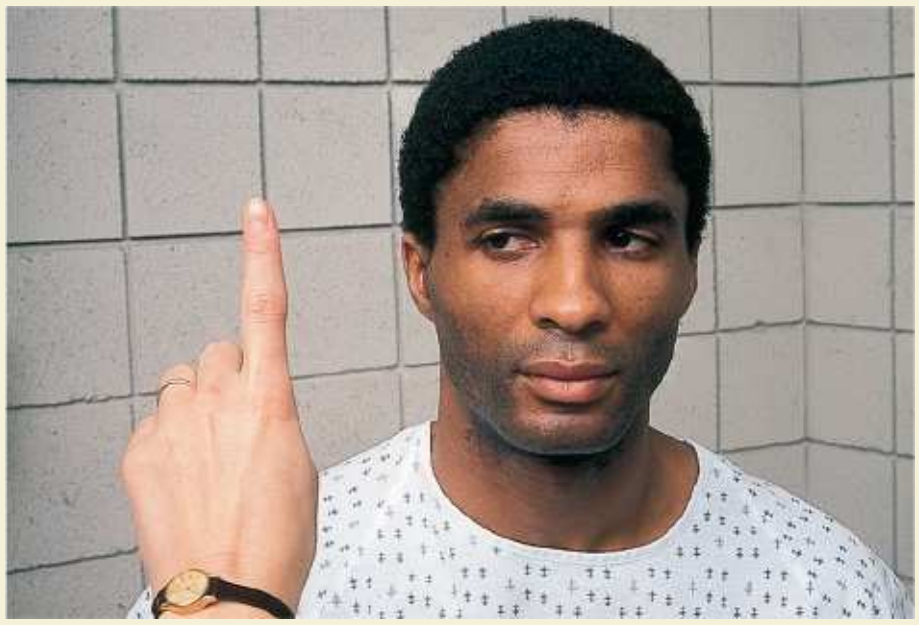
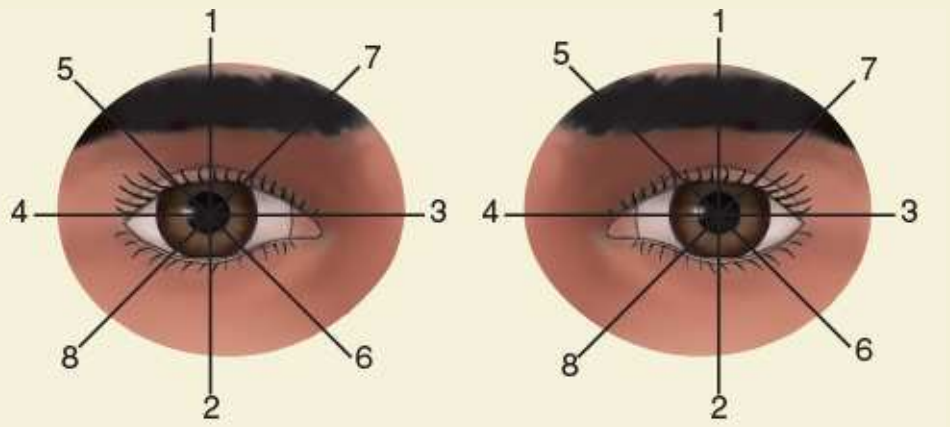
Guidelines for Nursing Care 27-3

Assessing Extraocular Movements and Peripheral Vision

Extraocular Movements



- Ask the patient to sit or stand about 2 ft away, facing you sitting or standing at eye level with the patient.
- Ask the patient to hold the head still and follow the movement of your forefinger or a penlight with the eyes.
- Keeping your finger or light about 1 foot from the patient's face, move it slowly through the cardinal positions: up and down, left and right, diagonally up and down to the left, diagonally up and down to the right (see figure).



Peripheral Vision

- Have the patient stand or sit about 2 ft away, facing you at eye level.
- Ask the patient to cover one eye with a hand or an index card.
- Ask the patient to look directly at your nose and fix the eyes on that spot.
- Cover your own eye opposite the patient's closed eye.
- Hold one arm outstretched to one side (right or left) equidistant from you and the patient, and move your fingers into the visual fields from various peripheral points.
- Ask the patient to tell you when the fingers are first seen (both you and the patient should see the fingers at the same time).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Repeat the procedure for the other eye.

Testing extraocular movement of the eye.

Inspecting and Palpating the Ears

Assess the external ear by inspection and palpation. Advanced health care providers usually perform assessment of the structures of the ear canal and tympanic membrane with an otoscope, which is an advanced assessment skill. Refer to a health assessment text for details.

Inspecting and Palpating the External Ear. Inspect the external ear (Fig. 27-10) for shape, size, and lesions. The external surfaces of the ear should be smooth, and the shape and size of the ears should be symmetric and proportional to the head. Abnormal findings include unequal height and size, uneven color, and lesions. Inspect the visible portion of the ear canal. Note the presence of cerumen (wax), edema, discharge, or foreign bodies. Gently palpate the external ear for pain, edema, or presence of lesions. Pain when manipulating the pinna is a symptom of an infection of the external ear.

Assessing Hearing and Sound Conduction. General hearing screening tests that are useful include self-report questionnaires and the whisper test. Self-report questionnaires can be administered in a verbal, written or computerized format and collect information related to patient reports of hearing ability and deficits, and associated impact on activities of daily living and quality of life. Screening of hearing using the whisper test is accomplished as follows: test hearing in one ear at a time by determining whether the patient can hear a whispered voice. Assess hearing acuity out of the patient's line of vision (to prevent lip reading), with the opposite ear covered. Determine whether the patient can hear a whispered sentence or group of numbers from a distance of 1 to 2 ft. Ask the patient to repeat what you said. Both screening tests can provide clues to identifying a need for further evaluation, such as an audiologic (hearing) evaluation by an audiologist (professional who provide prevention, identification, diagnosis and treatment of hearing, balance and other auditory disorders) (American Speech-Language Hearing Association, n.d.).

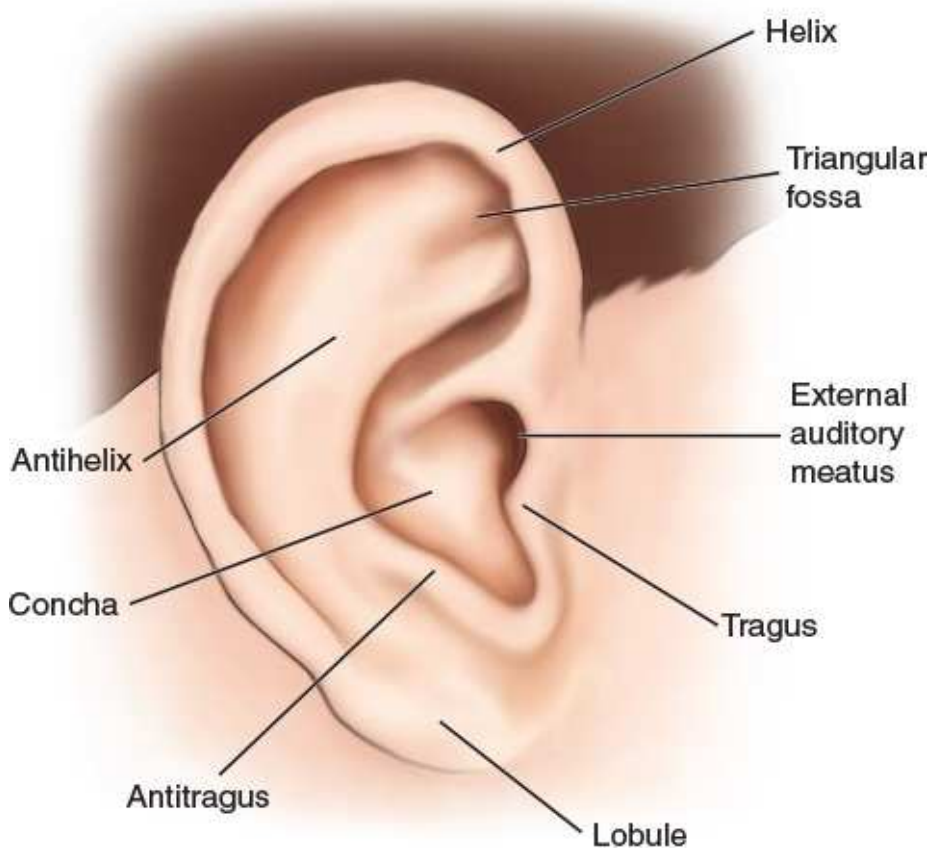


FIGURE 27-10. External structures of the ear.

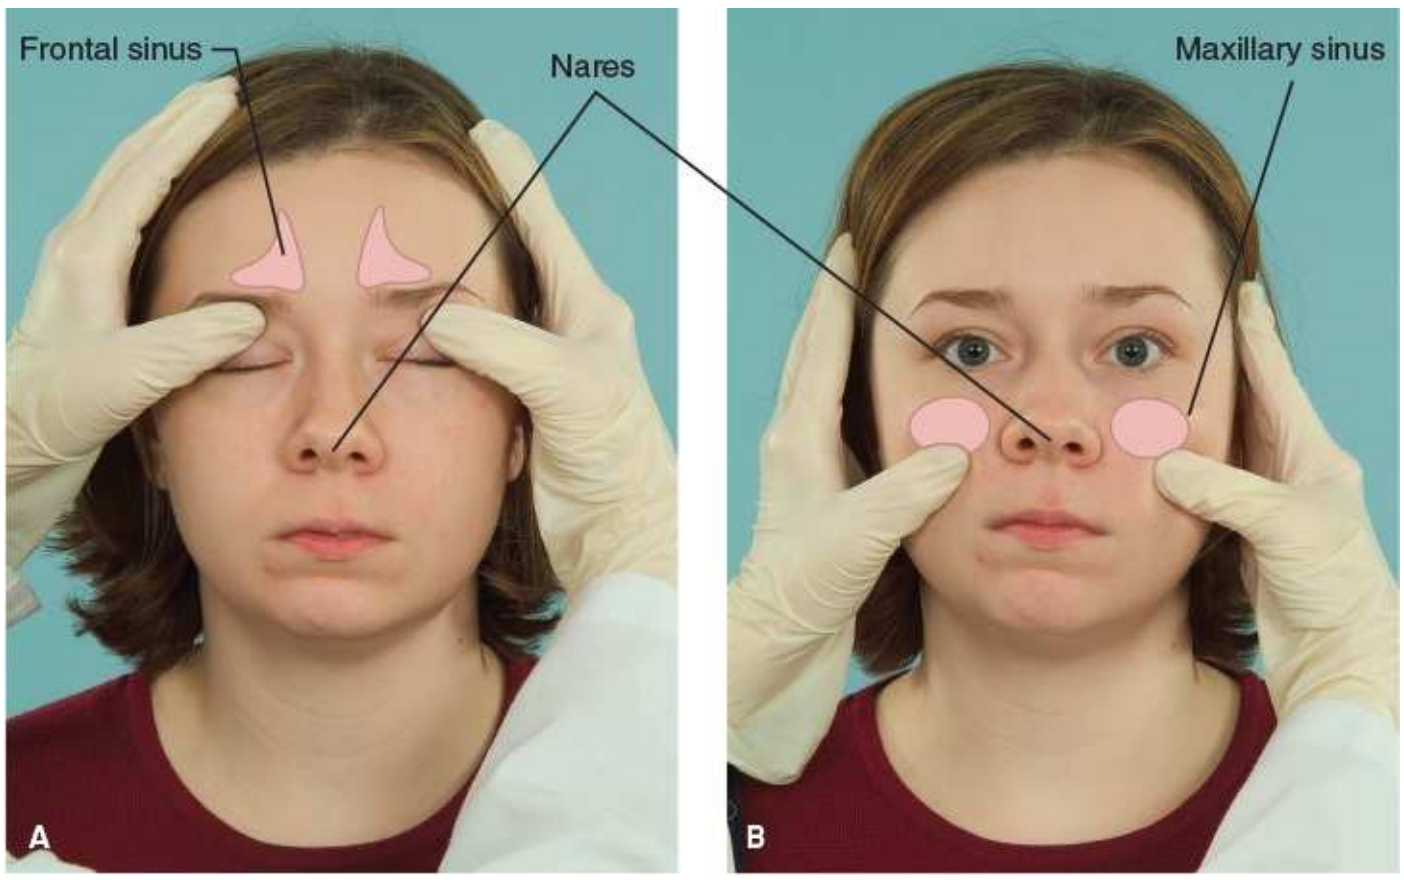

FIGURE 27-11. A. Nares and frontal sinuses. The frontal sinuses are palpated by gently pressing upward on the bony prominences above each eye. **B.** The maxillary sinuses are palpated by applying gentle pressure on the bony prominences of the upper cheek. (*Source:* Used with permission from Shutterstock. *Photos by B. Proud.*)

Inspecting the Nose

Assessment of the nose involves examining the external nose and the nares (Fig. 27-11A). Inspect the nose and inspect and palpate the sinuses with the patient sitting and their head slightly tilted back, if possible.

Assess the nose for patency by occluding one nostril at a time and asking the patient to inhale and exhale through the nose. Inspect each anterior nares by tipping the patient's head back slightly and shining a light into the nares. Examine the mucous membranes for color and the presence of lesions, exudate, or growths. Normally, the nasal mucosa is moist and darker red than the oral mucosa. Abnormal findings include swelling of the mucosa, and bleeding or discharge (indicating allergies with inflammation or infection).

Palpating the Sinuses

The frontal and maxillary sinuses, located in the frontal and maxillary bones, respectively, are palpated for pain and edema. The frontal sinuses are palpated by gently pressing upward on the bony prominences located above each eye (Fig. 27-11A). The maxillary sinuses are palpated by gentle pressure on the bony prominences of the upper cheek (Fig. 27-11B). Normally, the sinuses are not painful when palpated. Pain may be a finding if the sinuses are infected or obstructed.

Inspecting the Mouth and Pharynx

The mouth and pharynx include the lips, tongue, teeth, gums, hard and soft palate, salivary gland, tonsillar pillars, and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

tonsils (Fig. 27-12). Equipment used to assess the mouth, pharynx, and neck includes a penlight, a tongue blade, a 4 × 4-inch gauze sponge, and gloves.

Assess the mouth and pharynx by inspecting the lips, gums and teeth, tongue, under the tongue, and hard and soft palates. Have the patient sit with the head tilted backward, if possible, and the mouth opened wide. Use palpation if any abnormalities are noted during inspection. Wear gloves when assessing a patient's mouth and use 4 × 4-inch gauze to hold the tongue for palpation.

The lips should be pink, moist, and smooth. The tongue and mucous membranes are normally pink, moist, and free of swelling or lesions. If the patient wears dentures, ask the patient to remove them for inspection of the gums and roof of the mouth. The gums should be pink and smooth. With the patient's tongue relaxed on the floor of the mouth, examine the mucous membrane of the oropharynx while depressing the base of the tongue with a tongue depressor. The uvula is normally centered and freely movable. The tonsils, if present, are small, pink, and symmetric in size. The teeth should be regular and free of cavities or have dental restoration.

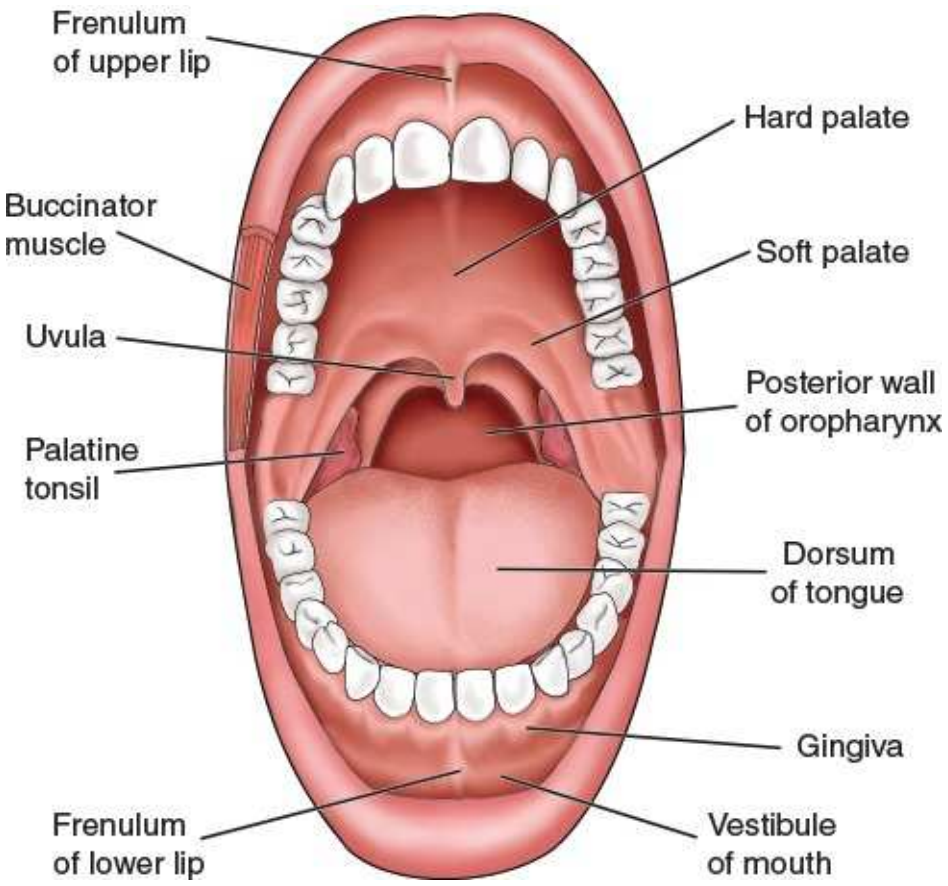

FIGURE 27-12. Structures of the mouth.

Abnormal findings include pallor, cyanosis, or redness and swelling of the mucous membranes; lesions of the mucosa and lips; swollen, red tonsils (indicating infection); swollen, red, and bleeding gums (from nutritional deficits, inflammation or infection, poorly fitted dentures, or poor oral hygiene); poorly aligned, missing, or carious teeth; a white coating on the tongue (from poor oral hygiene, irritation, or smoking); a fissured tongue (from dehydration); a bright-red tongue (seen in deficiencies of iron, vitamin B_{12}, or niacin); or a black, hairy tongue (from antibiotic use).

Inspecting and Palpating the Neck

Assessments of the neck include the trachea, lymph nodes, and thyroid gland (Fig. 27-13). Assess the neck with the patient sitting and the neck slightly hyperextended, if possible. Ask the patient to tilt the head backward, forward, and side to side to assess range of motion (ROM). The neck should be symmetric, with smooth and controlled ROM. Also assess the neck for venous distention. No neck vein distention (indicating heart problems) should be visible. Palpation of the thyroid is an advanced assessment skill, usually performed by advanced health care providers. Refer to a health assessment text for details.

Inspecting and Palpating the Trachea. Assess the position of the trachea in the neck. Inspect and palpate the trachea. The trachea should be midline and symmetrical.

Inspecting the Thyroid Gland. Assess the thyroid gland with the neck slightly hyperextended. Observe the lower portion of the neck overlying the thyroid gland. Assess for symmetry and visible masses. Ask the patient to swallow. Observe the area while the patient swallows. Offer a glass of water, if necessary, to make it easier for the patient to swallow.

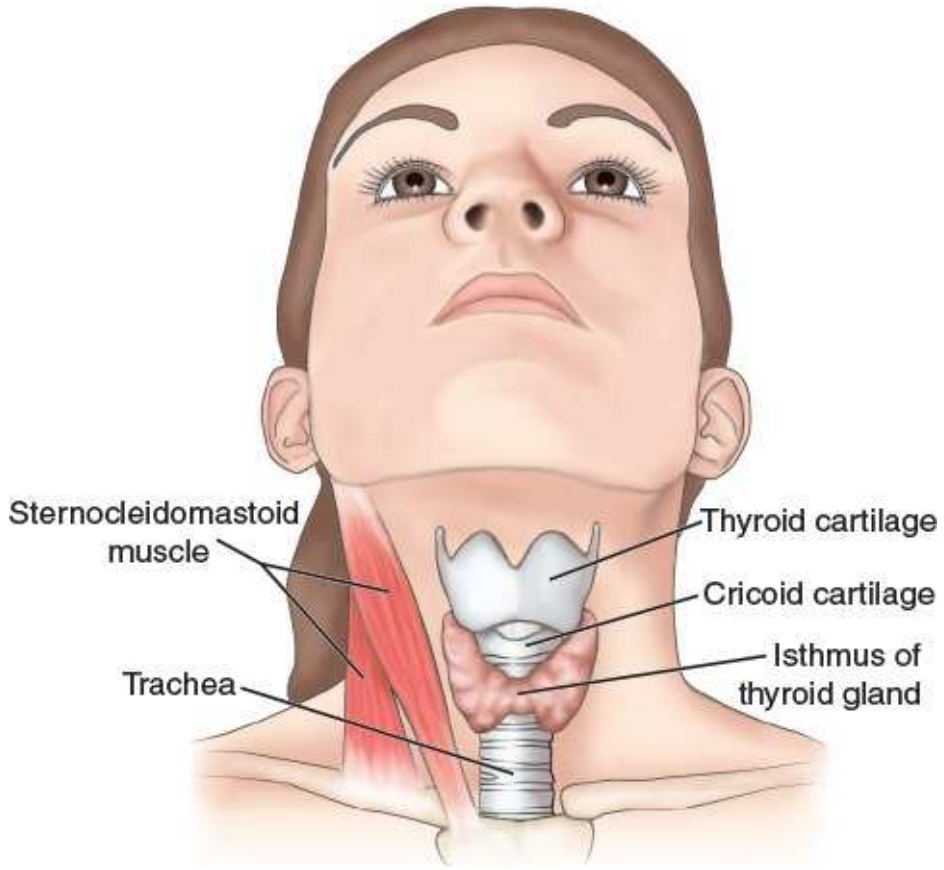

FIGURE 27-13. Structures of the neck.

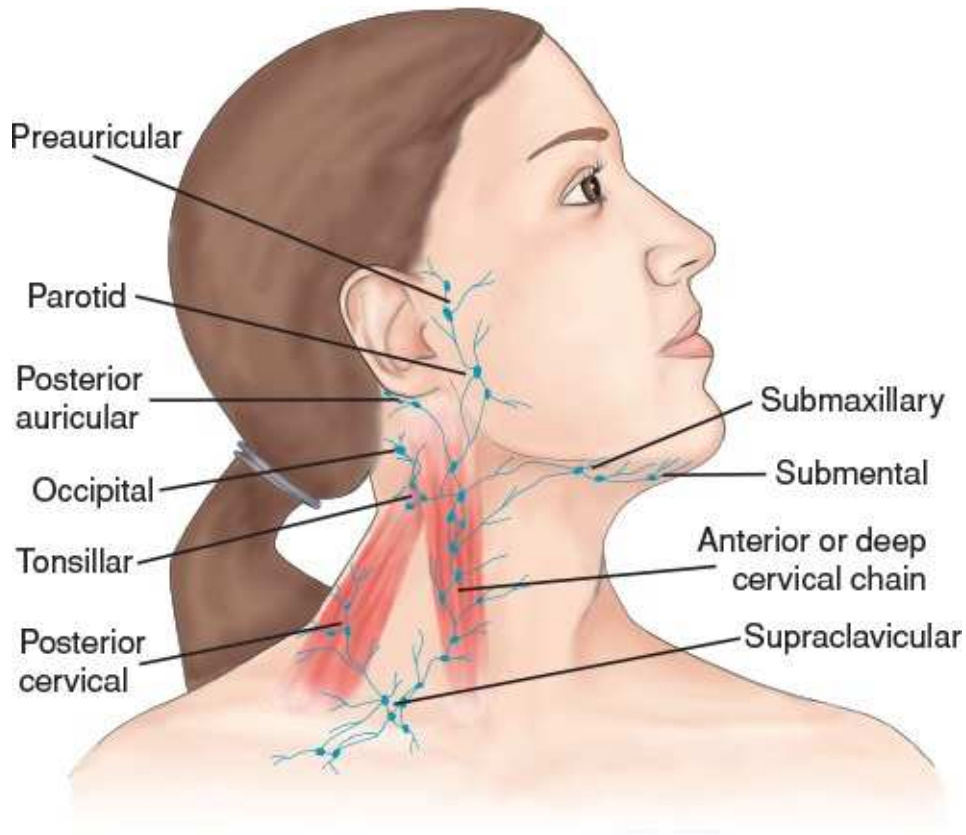

FIGURE 27-14. Location of the lymph nodes of the neck.

Abnormal findings include asymmetry, enlargement, lumps, and bulging. These findings may indicate the presence of enlargement of the thyroid (a goiter), inflammation of the thyroid (thyroiditis), or cancer of the thyroid.

Palpating the Lymph Nodes. Palpate the lymph nodes (Fig. 27-14) with the pads of the fingers for enlargement, tenderness, and mobility. The nodes are generally not palpable; if palpable, they should be small, mobile, smooth, and nontender. If lymph nodes are palpable, assess location, size, consistency, mobility, and tenderness. Enlarged lymph nodes (lymphadenopathy) may indicate infection, autoimmune disorders, or metastasis of cancer.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common head and neck variations in newborns and children include:

- Closing of posterior fontanel at age 8 weeks, soft anterior fontanel at about age 18 months
- Gazing at and following bright objects by age 1 month
- Focusing with both eyes by age 6 months
- Pupils at the inner folds (pseudostrabismus)
- Startle reflex in newborns

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common head and neck variations in the older adult include:

- Impaired near vision (presbyopia)
- Decreased color vision and peripheral vision

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Decreased adaptation to light and dark
- A white ring around the cornea (arcus senilis)
- Entropion (eyelid turns inward) and ectropion (eyelid turns outward)
- Hearing loss (presbycusis)
- Elongated ear lobes
- Decreased neck ROM
- Smaller, more easily palpated lymph glands

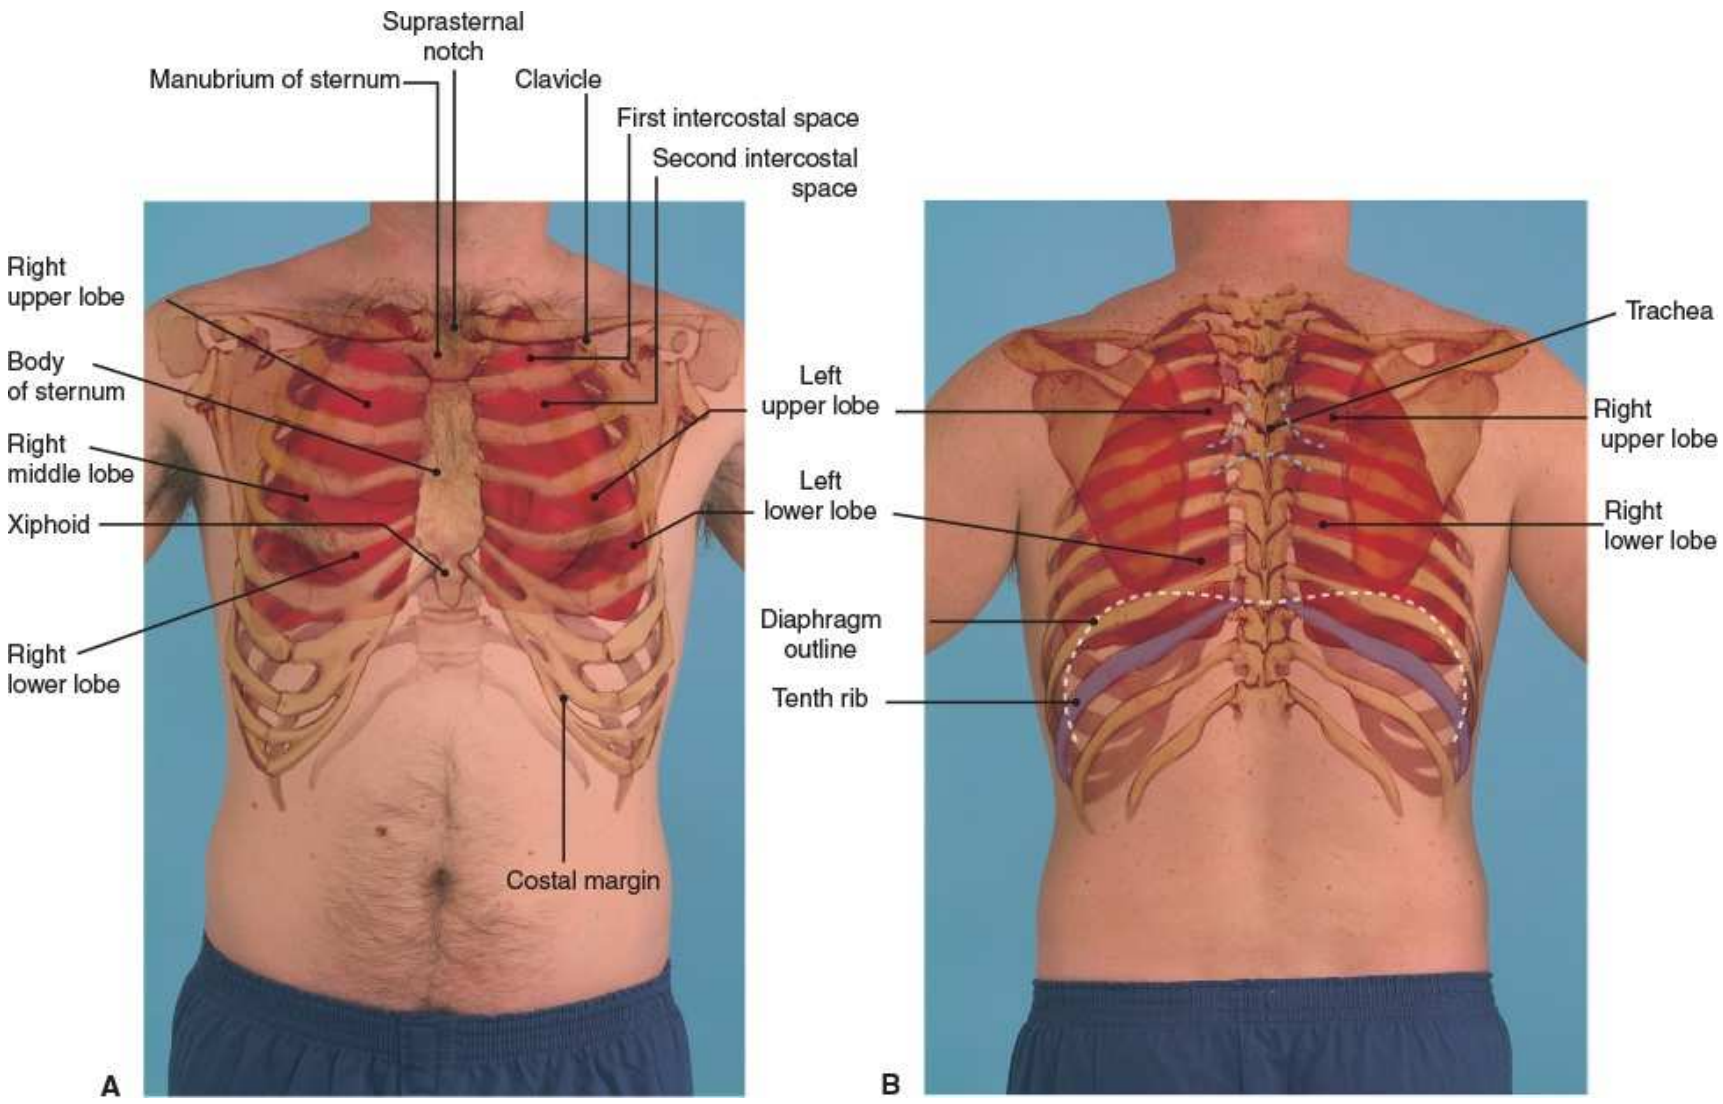

FIGURE 27-15. Thoracic landmarks. **A.** Anterior. **B.** Posterior.

Assessing the Thorax and Lungs

The thorax (Fig. 27-15) comprises the lungs, rib cage, cartilage, and intercostal muscles. Data from the health history may elicit a health problem, such as dyspnea or chest pain, as well as information about sleep patterns, cough, and sputum. A history of smoking indicates the need to include ways to stop smoking in the care plan. Environmental exposure to certain inhalants (such as secondhand smoke, paint, air pollution, or asbestos fibers) in the home or workplace may increase the risk of respiratory diseases and cancer. Physical examination provides data about the bony structures of the thorax, respiratory effort, chest expansion, and breath sounds. Additional information related to assessment of the thorax and lungs is discussed in Chapters 26 and 40.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of trauma to the ribs or lung surgery
- Number of pillows used when sleeping
- History of chest pain with deep breathing
- History of persistent cough with or without producing sputum
- History of allergies
- Environmental exposure to chemicals, asbestos, or smoke
- History of smoking (how long, how many packs/day)
- History of lung disease in family members or self
- History of frequent or chronic respiratory infections

PHYSICAL ASSESSMENT

Physical assessment of the thorax and lungs requires a stethoscope and a watch. Make sure that the environment is warm and adequately lit. The techniques for this assessment include inspection, palpation, percussion, and auscultation. The patient may be in a sitting position or in a supine position with the head raised about 30 degrees, if possible. Percussion of the thorax is an advanced assessment technique, usually performed by advanced health care providers. Refer to a health assessment text for details.

Inspecting the Thorax

Begin inspection by observing the patient's chest for color, shape or contour, breathing patterns, and muscle development. The color should be even and consistent with the color of the patient's face. The shape or contour should have a downward equal slope at the rib cage. The chest should be symmetric, with the transverse diameter greater than the anteroposterior diameter. An increased anteroposterior diameter, as seen in chronic lung diseases, is described as barrel chest (Fig. 27-16). Respirations should be smooth and even, ranging from 12 to 20 breaths/min (adults). Additional information related to assessment of respiration is discussed in Chapter 26.

Abnormal findings include an increase in chest size and contour, abnormal breathing patterns with use of accessory muscles (the major neck muscles, the sternocleidomastoid and trapezius muscles; symptom of difficulty breathing and/or respiratory disease, such as chronic obstructive pulmonary disease or asthma), unequal chest expansion (may occur in chest trauma or pneumonia), and abnormal respirations.

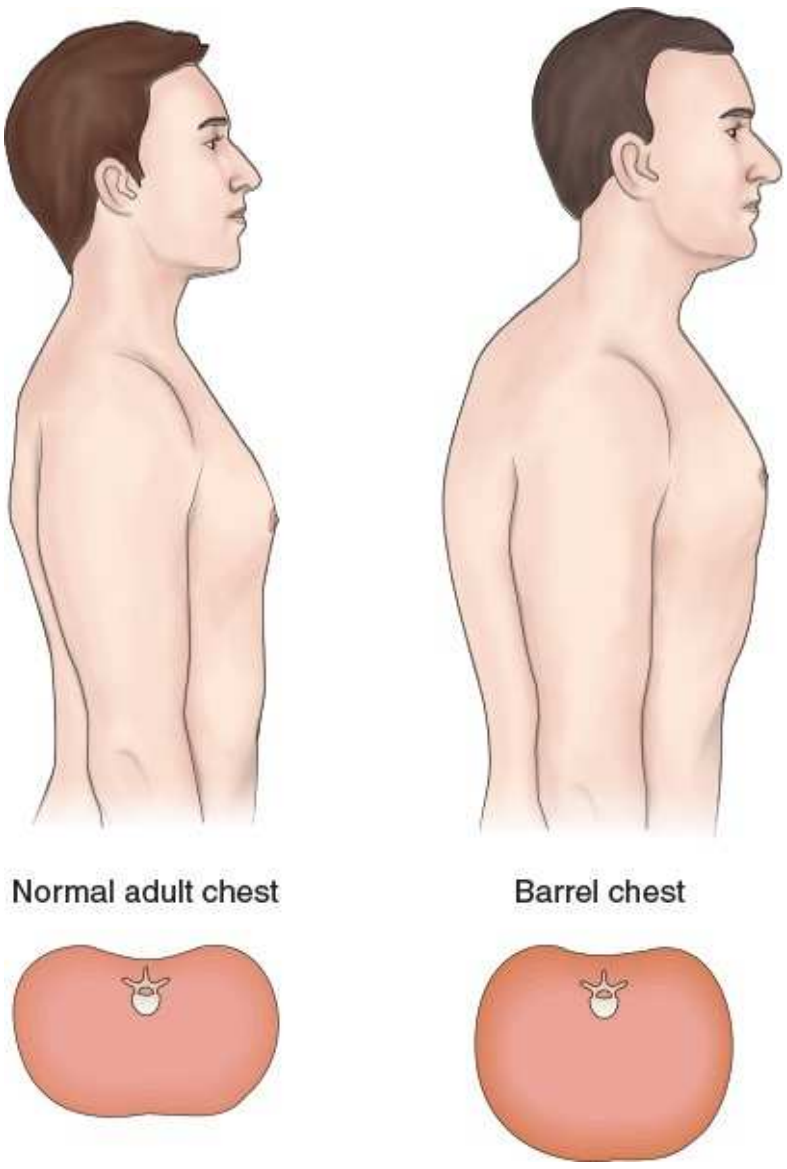

FIGURE 27-16. Profile and anteroposterior diameter of normal adult chest and barrel chest.

Palpating the Thorax

Palpation is used to detect areas of sensitivity, chest expansion during respirations, and vibrations (fremitus). Use the palmar surface of the hands to palpate the anterior and posterior thoracic landmarks (Fig. 27-17) in a sequential pattern for temperature, moisture, muscular development, and any tenderness or masses. The skin should be warm and dry, with symmetric muscular development, and no tenderness, masses, or vibrations. Abnormal findings may be cool or excessively dry or moist skin, muscle asymmetry, tenderness, masses, and vibrations.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

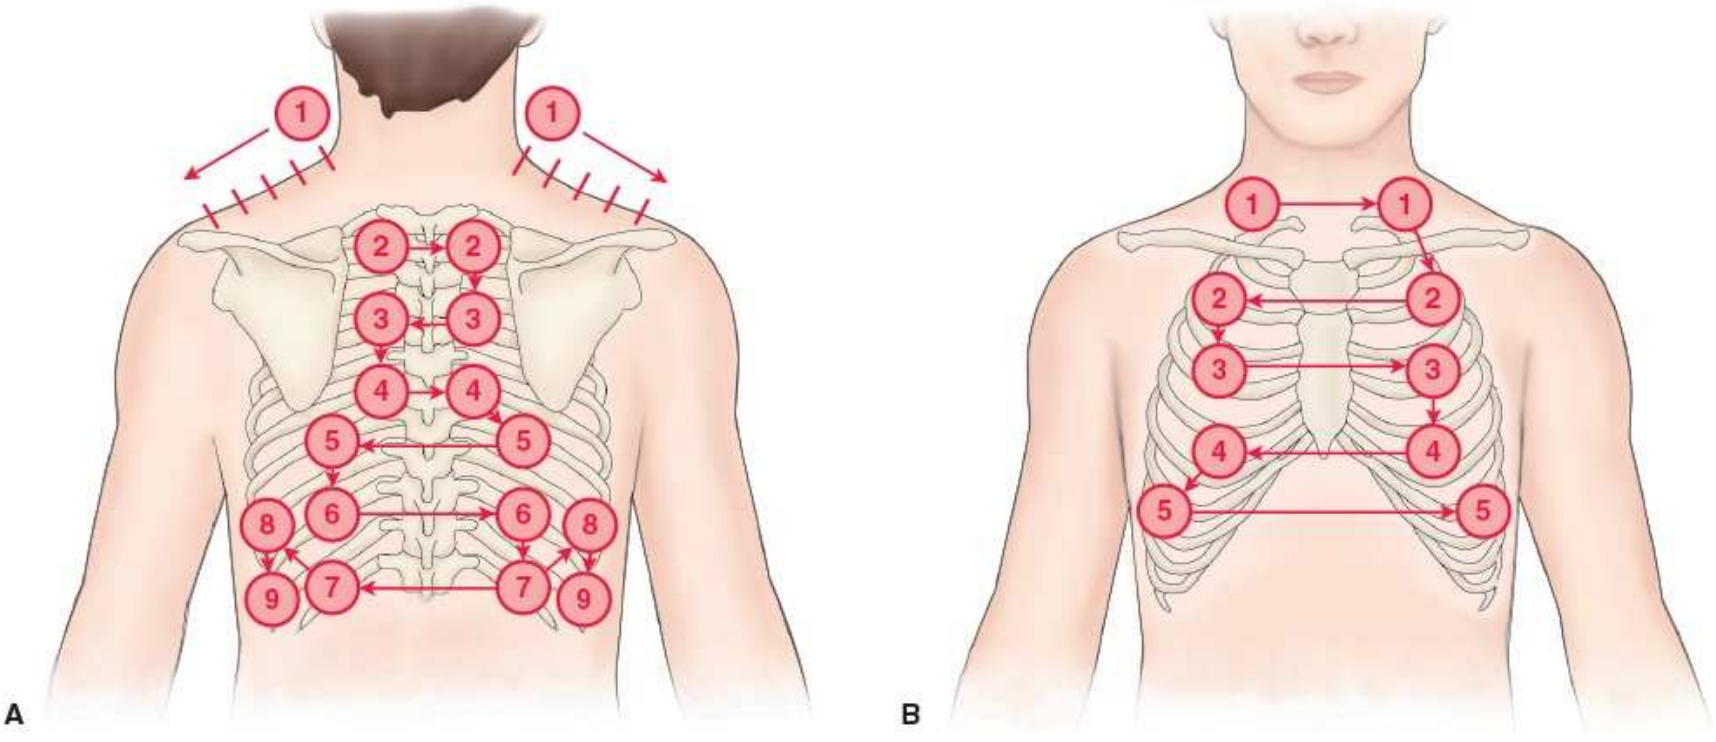

FIGURE 27-17. Posterior (**A**) and anterior (**B**) chest—landmarks and systematic sequence of assessment. The pattern is used for palpation, percussion, and auscultation of the chest.

Chest expansion is determined by placing the hands over the posterior chest wall, with the fingers at the level of T9 or T10 (Fig. 27-18A on page 800). Ask the patient to take a deep breath, and observe the movement of your thumbs. The thorax should expand symmetrically (Fig. 27-18B on page 800).

Auscultating Breath Sounds

Auscultation is used to detect airflow within the respiratory tract. Ask the patient to breathe slowly and deeply through the mouth. Place the warmed diaphragm of the stethoscope over the thoracic landmarks and auscultate breath sounds in the same sequential pattern as used for palpation (see Fig. 27-17). Normally, breath sounds result from the free movement of air into and out of all parts of the bronchial tree. Listen for the duration, pitch, and intensity of the sounds.

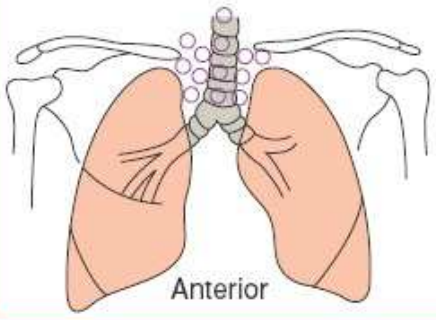
Normal breath sounds (Table 27-2 on page 800) vary over different parts of the lungs. **Bronchial breath sounds** heard over the larynx and trachea are high-pitched, harsh "blowing" sounds, with sound on expiration being longer than inspiration. **Bronchovesicular breath sounds** are heard over the mainstem bronchus and are moderate blowing sounds, with inspiration equal to expiration. **Vesicular breath sounds** are soft, low-pitched, whispering sounds, heard over most of the lung fields, with sound on inspiration being longer than expiration.

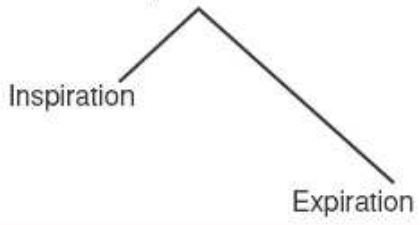
Adventitious breath sounds (extra, abnormal sounds) are not normally heard in the lungs and result from air moving through moisture, mucus, or narrowed airways. These abnormal sounds also result from sudden opening of collapsed alveoli. Refer to Table 27-3 (on page 801) for an explanation of these abnormal sounds. If any of these sounds are heard, listen for the loudness, pitch, duration, timing in the respiratory cycle (inspiration vs. expiration), location on the chest wall, variations with breathing, and any change after a cough or deep breath (Jensen, 2019). If a productive cough occurs during assessment of the thorax and lungs, the sputum should be assessed for color, consistency, and amount.

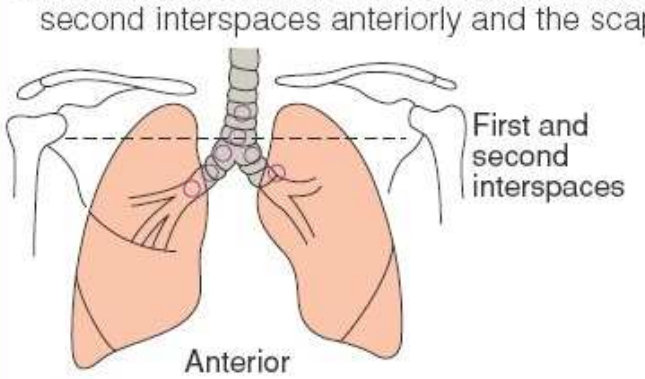
FIGURE 27-18. Palpating the posterior thorax excursion. The examiner's hands are placed symmetrically on the patient's back (**A**). As the patient inhales, the examiner's hands should move apart symmetrically (**B**). (*Source:* Used with permission from Shutterstock.

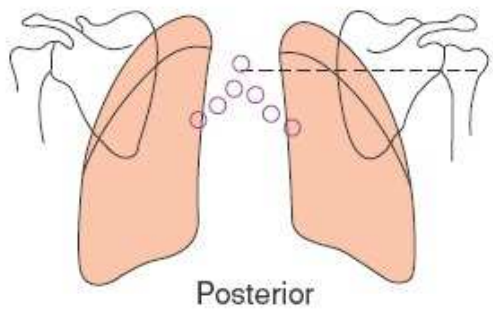
Photos by B. Proud.)

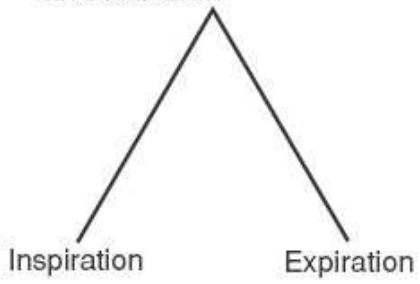
Table 27-2 Normal Breath Sounds

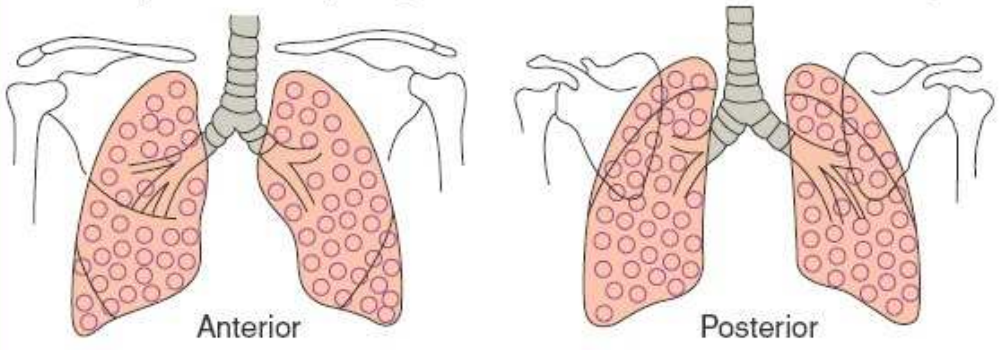


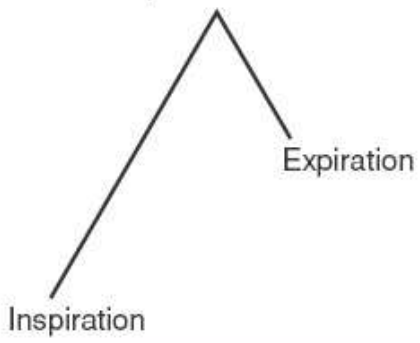


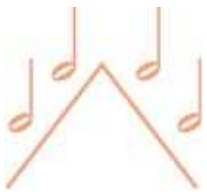












TYPE, DESCRIPTION, AND LOCATION	RATIO OF INSPIRATION TO EXPIRATION
Bronchial or Tubular Blowing, hollow sounds; auscultated over the larynx and trachea 	Sound on expiration is longer, lower, and higher pitched than inspiration 
Bronchovesicular Medium-pitched, medium intensity, blowing sounds; auscultated over the first and second interspaces anteriorly and the scapula posteriorly  	Inspiration and expiration sounds have similar pitch and duration 
Vesicular Soft, low-pitched, whispering sounds; heard over most of the lung fields 	Sound on inspiration is longer, louder, and higher pitched than expiration 

Table 27-3 Adventitious Breath Sounds

TYPE AND CHARACTERISTICS	ILLUSTRATION
Wheeze (Sibilant) Musical or squeaking High-pitched, continuous sounds Auscultated during inspiration and expiration Air passing through narrowed airways	
Rhonchi (Sonorous Wheeze) Sonorous or coarse; snoring quality Low-pitched, continuous sounds Auscultated during inspiration and expiration Coughing may clear the sound somewhat Air passing through or around secretions	
Crackles Bubbling, crackling, popping Low- to high-pitched, discontinuous sounds Auscultated during inspiration and expiration Opening of deflated small airways and alveoli; air passing through fluid in the airways	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Stridor Harsh, loud, high-pitched Auscultated on inspiration Narrowing of upper airway (larynx or trachea); presence of foreign body in airway	
Friction Rub Rubbing or grating Loudest over lower lateral anterior surface Auscultated during inspiration and expiration Inflamed pleura rubbing against chest wall	

Think back to **Billy Collins**, the 9-year-old who was stung by a bee. Incorporating knowledge of the signs and symptoms of an allergic reaction, the nurse would inspect Billy's chest for accessory muscle use and auscultate his lungs, noting any evidence of wheezing, which is commonly observed with allergic reactions.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common thorax and lung variations in newborns and children include:

- Louder breath sounds on auscultation
- More rapid respiratory rate (until ages 8 to 10 years)
- Use of abdominal muscles during respiration (infants and young children up to school age)

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common thorax and lung variations in older adults include:

- Increased anteroposterior chest diameter
- Increase in the dorsal spinal curve (kyphosis)
- Decreased thoracic expansion
- Use of accessory muscles to exhale

Assessing the Cardiovascular and Peripheral Vascular Systems

Cardiovascular and peripheral vascular assessment includes assessment of the heart and the extremities. Questions in the health history can identify supporting subjective data such as leg pain, chest pain, or dyspnea on exertion. Data can also be used to identify ADLs and health behaviors that increase the risk of cardiovascular disease, including smoking, lack of exercise, and a diet high in calories, fats, and salt. If these risks are identified, the plan of care should include referral for additional diagnostic testing and teaching about health-promotion activities. The physical examination is used to identify signs and symptoms of heart disease and peripheral vascular disease (most often found in the lower extremities). Additional information related to assessment of the cardiovascular and peripheral vascular systems is discussed in Chapters 26 and 40.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of chest pain, palpitations, or dizziness
- Swelling in the ankles and feet
- Number of pillows used to sleep
- Type and amount of medications taken daily
- History of heart defect, rheumatic fever, or chest or heart surgery
- Personal or family history of hypertension (high blood pressure), myocardial infarction (heart attack), coronary artery disease, high blood cholesterol levels, or diabetes mellitus
- History of smoking (how long, how many packs/day)
- Type and amount of exercise
- Usual foods eaten each day
- Changes in color or temperature of the extremities
- History of pain in the legs when sleeping or pain that is worsened by walking

- History of blood clots or sores on the legs that do not heal

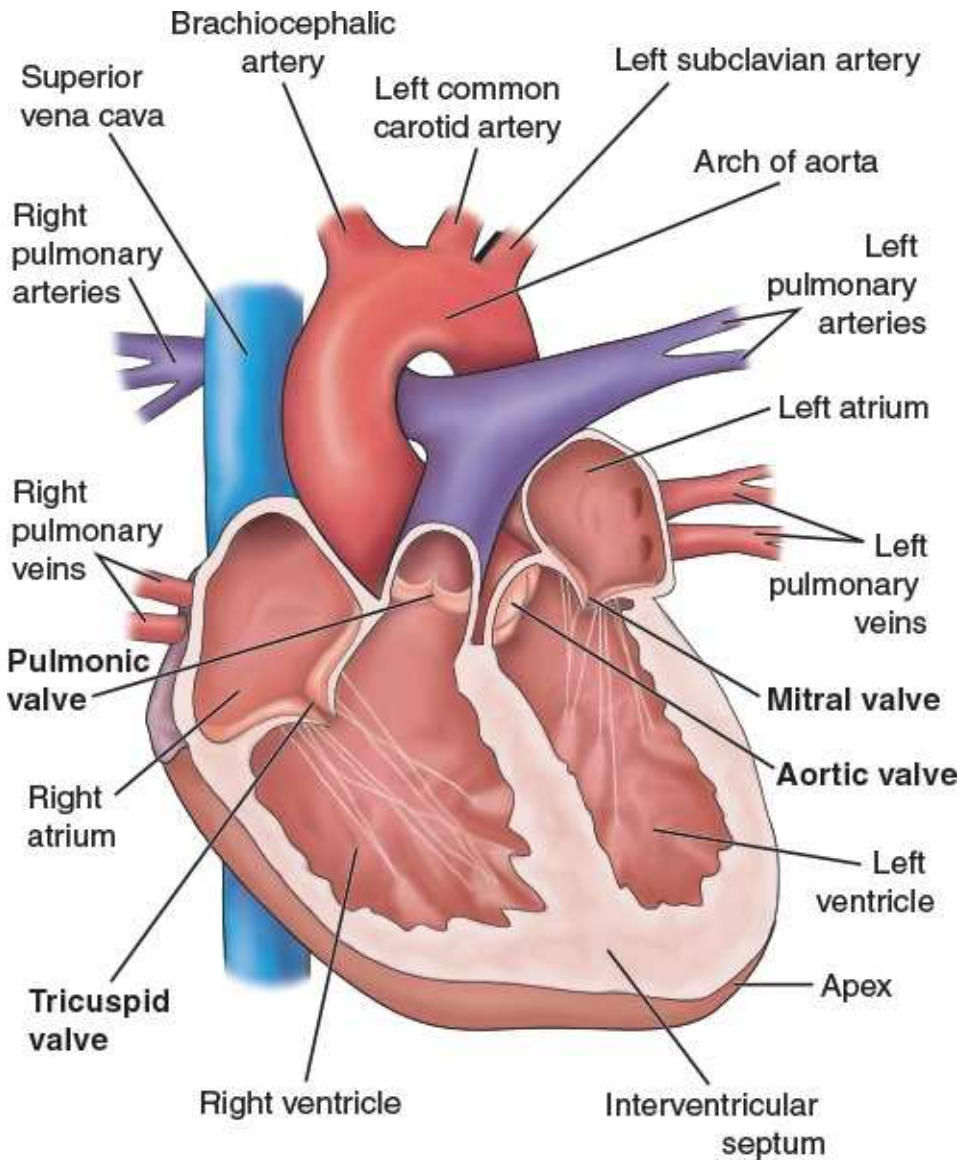


FIGURE 27-19. View of the interior of the heart showing the atrioventricular and semilunar valves responsible for heart sounds.

PHYSICAL ASSESSMENT

The techniques used for cardiovascular assessment are inspection, palpation, and auscultation. Necessary equipment includes a stethoscope with a bell and diaphragm, an electronic oscillometric device or sphygmomanometer to measure blood pressure, and a watch. The patient may be in a sitting position or in a supine position with the head raised about 30 degrees, if possible. Adequate lighting is essential for inspection of color and for pulsations. A quiet environment is necessary for accurate auscultation of heart sounds. Figure 27-19 provides a view of the heart, including the heart valves responsible for heart sounds.

Peripheral vascular assessment includes measuring the blood pressure and assessing the skin and perfusion of the extremities and the peripheral pulses. Assessments are made by inspection and palpation, with the patient sitting or supine. Use of an electronic oscillometric device to measure blood pressure is preferred over the auscultatory method of measurement (Muntner et al., 2019). Refer to Chapter 26 for a detailed discussion of measurement of blood pressure.

Peripheral vascular assessments may be combined with assessment of other body areas. Many health care providers assess the neuromuscular, musculoskeletal, and peripheral vascular systems as an integrated assessment. Refer to Skill 27-2 (on pp. 824–830) for an example of a systematic, integrated assessment of these systems.

Inspecting the Neck and Precordium

Observe the neck and **precordium** (the portion of the body over the heart and lower thorax, encompassing the aortic, pulmonic, tricuspid, and apical areas, and Erb's point) (Fig. 27-20) for visible pulsations. Pulsations usually are absent except for the apical impulse, located at about the fourth or fifth intercostal space at the left midclavicular line. Inspect the epigastric area at the tip of the sternum for pulsation of the abdominal aorta. Findings of neck vein distention (indicating heart disease) or visible pulsations in precordial areas other than the apical impulse (which may result from abnormalities of the ventricle) are considered abnormal.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

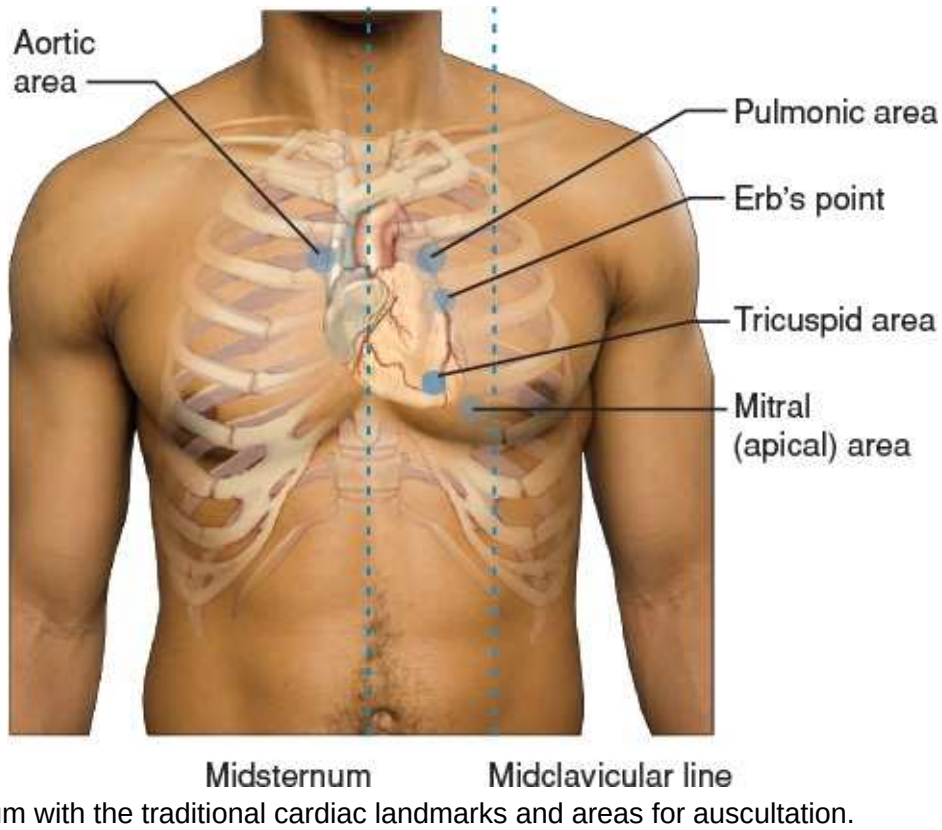

FIGURE 27-20. The precordium with the traditional cardiac landmarks and areas for auscultation.

Palpating the Neck and Precordium

Palpate the carotid artery medial to the sternomastoid muscle in the neck between the jaw and the clavicle, in the lower third of the neck (Fig. 27-21) (Jensen, 2019). Palpate the carotid arteries one at a time to avoid obstructing both arteries simultaneously, reducing blood flow to the brain and potentially causing dizziness or loss of consciousness (Jensen, 2019). Note the strength of the pulse and grade it as with peripheral pulses (refer to discussion later in this section on page 804). Normal findings include equal pulses bilaterally, with a strength of +2. Abnormal findings include an absent pulse; a diminished (weak) or thready pulse (which may indicate decreased cardiac output); a forceful or bounding pulse (seen in hypertension and circulatory fluid overload); and an asymmetric pulse (related to impaired circulation). Additional information related to assessment of the pulses is discussed in Chapter 26.

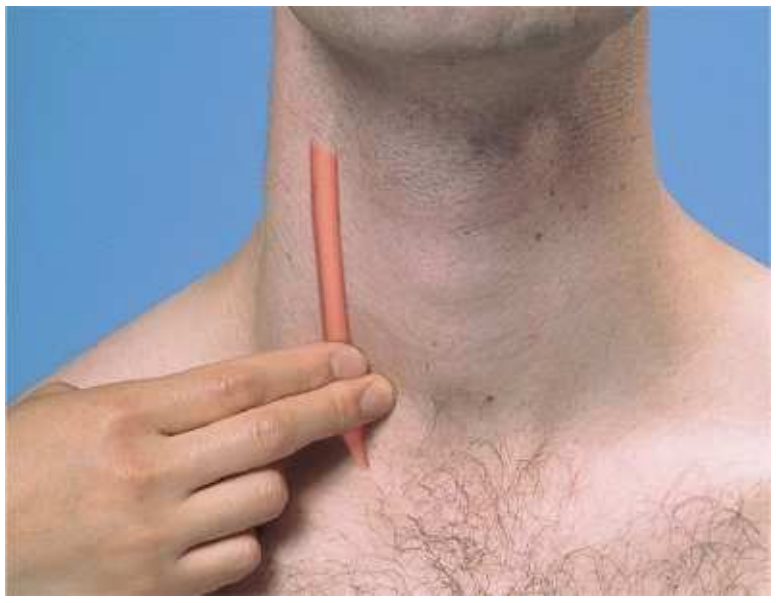

FIGURE 27-21. Palpate the carotid artery medial to the sternomastoid muscle in the neck between the jaw and the clavicle. (*Source:* Jensen, S. [2010]. Nursing health assessment: A best practice approach [1st ed.]. Wolters Kluwer Health.)

FIGURE 27-22. Palpating areas of the precordium: (**A**) aortic area, (**B**) pulmonic area, and (**C**) apical (mitral) and tricuspid area. (*Source:* Used with permission from Shutterstock. *Photos by Ken Kasper.*)

Using the palmar surface of the hand with the four fingers held together, gently palpate the precordium for pulsations (Fig. 27-22). Palpate in a systematic manner, assessing specific cardiac landmarks—the aortic (A), pulmonic (B), tricuspid, and mitral areas (C), as well as Erb's point. Palpate the apical impulse in the mitral area. Note size, duration, force, and location in relationship to the midclavicular line. Normal findings include no pulsation palpable over the aortic and pulmonic areas, with a palpable apical impulse. Abnormal findings include precordial thrills, which are fine, palpable, rushing vibrations over the right or left second intercostal space, and lifts or heaves, which involve a rise along the border of the sternum with each heartbeat.

Auscultating the Carotid Arteries

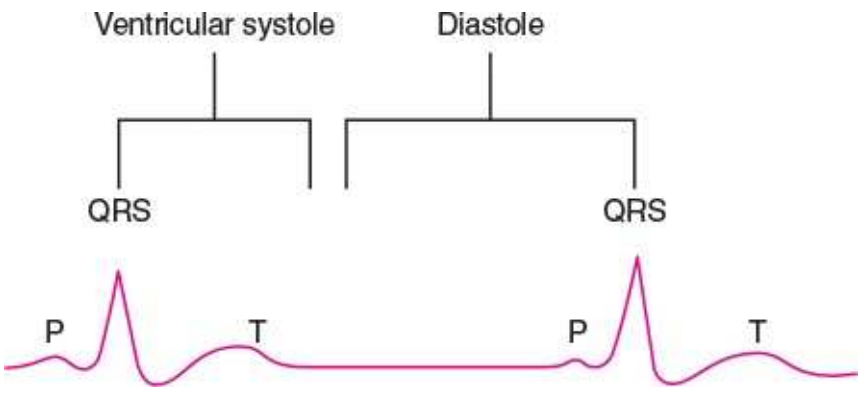
Using the bell of the stethoscope, auscultate over the carotid arteries for bruits. Bruits are abnormal "swooshing or blowing" sounds heard over a blood vessel, caused by blood that is swirling in the vessel rather than normal smooth flow. A bruit may be heard in the presence of stenosis (narrowing) or occlusion of an artery. Bruits may also be caused by abnormal dilation of a vessel. Report and document changes in vascular sounds.

Auscultating Heart Sounds

Auscultation is used to determine the heart sounds caused by closure of the heart valves. Ask the patient to breathe normally. Use systematic auscultation, beginning at the aortic area, moving to the pulmonic area, then to Erb's point, then to the tricuspid area, and finally to the mitral area (see Fig. 27-20). Use the diaphragm of the stethoscope first to listen to high-pitched sounds. Then use the bell to listen to low-pitched sounds. Focus on the overall rate and rhythm of the heart and the normal heart sounds (Box 27-7 on page 804).

Abnormal findings include extra heart sounds at any of the cardiac landmarks and abnormal rate or rhythm. Extra heart sounds are often heard when the patient has anemia or heart disease. A wide variety of conditions may alter the normal heart rate or rhythm, including serious infections, diseases of the heart muscle or conducting system, dehydration or overhydration, endocrine disorders, respiratory disorders, and head trauma. Extra heart sounds may be S_3, S_4, or murmurs.

S_3, known as the third heart sound, follows S_2 and is often represented by a "lub-dub-dee" pattern ("dee" being S_3). This sound is best heard with the stethoscope bell at the mitral area, with the patient lying on the left side. S_3 is considered normal in children and young adults and abnormal in middle-aged and older adults. S_4 is the fourth heart sound, occurring right before S_1, and is often represented by a "dee-lub-dub" pattern ("dee" being S_4). S_4 is considered normal in older adults but abnormal in children and adults. Heart murmurs are extra heart sounds caused by some disruption of blood flow through the heart. The characteristics of a murmur and grading depend on the adequacy of valve function, rate of blood flow, and size of the valve opening. In clinical practice, nurses are more concerned with



for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

recognizing changes in murmurs rather than in diagnosing and labeling them (Jensen, 2019, p. 467). Refer to a health assessment text for grading details and additional information related to assessment of heart sounds.

Box 27-7 Normal Heart Sounds

During auscultation, the first heart sound, called S_1, is heard as the "lub" of "lub-dub." This sound occurs when the mitral and tricuspid valves close and corresponds to the onset of ventricular contraction (see figure). The sound, low-pitched and dull, is heard best at the apical area. The second heart sound, S_2, occurs at the termination of systole and corresponds to the onset of ventricular diastole. The "dub" of "lub-dub" represents the closure of the aortic and pulmonic valves. The sound of S_2 is higher pitched and shorter than S_1. The two sounds occur within 1 second or less, depending on the heart rate.

Normal findings include S_1, that is louder at the tricuspid and apical areas, with S_2 louder at the aortic and pulmonic areas.

Heart sounds in relation to the cardiac cycle and an electrocardiogram.

Inspecting the Extremities

Inspect the skin of the extremities for color, temperature, continuity, lesions (as described previously for assessment of the integument), venous patterns, and edema. Normally, venous patterns, varicosities, rashes, ulcers, or edema are absent on the lower extremities. However, if the patient has peripheral vascular disease (resulting in decreased blood flow and oxygenation of tissues), the skin of the lower extremities is typically pale and cool, shiny with brown discolorations, and hairless. The toenails are thickened. Phlebitis (inflammation of a vein) of the lower extremity is indicated by pain, redness, and swelling of the affected calf or thigh.

FIGURE 27-23. Assessing capillary refill. (*Source:* Jensen, S. [2019]. Nursing health assessment: A best practice approach [3rd ed.]. Wolters Kluwer Health.)

Palpating Peripheral Pulses and Capillary Refill

Use the pads of the index and middle fingers to palpate peripheral pulses for amplitude and symmetry. Palpate, carefully and one at a time, the carotid, brachial, radial, femoral, popliteal, dorsalis pedis, and posterior tibial pulses (see Fig. 26-3 on page 730). These pulses should be strong and equal bilaterally. The strength (amplitude) of the pulses, with a scale that may be used for documentation, is described in Table 26-5 on page 728. Assess capillary refill by using your thumb and forefinger to squeeze the patient's fingernail or toenail until it blanches (turns white). Release the pressure and observe the time it takes for normal color to return (Fig. 27-23). Normal capillary refill is <3 seconds (Jensen, 2019). Additional information related to assessment of pulses is discussed in Chapter 26.

Abnormal findings include an absent, weak, or thready pulse (which may indicate a decreased cardiac output), a forceful or bounding pulse (seen in hypertension and circulatory fluid overload), and an asymmetric pulse (related to impaired circulation). Prolonged capillary refill is associated with alterations in peripheral perfusion, edema, and cardiac

output.

Other assessments to determine arterial blood flow include Allen's test and Buerger's test, which are usually performed by advanced practice professionals and are not discussed here. Refer to an assessment text for details.

Assessing Neurovascular Status

Assessment of neurovascular status is an important nursing intervention leading to early identification of neurovascular impairment and timely intervention (Agency for Clinical Innovation, 2018; Johnston-Walker & Hardcastle, 2011; Turney et al., 2013). Musculoskeletal trauma, crush injuries, orthopedic surgery, and external pressure from a cast or tight-fitting bandage can cause damage to blood vessels and nerves. This damage causes localized inflammation and tissue edema, which can lead to significantly diminished perfusion and severe ischemia, with resulting severe and permanent dysfunction of the affected area and/or loss of a limb. A neurovascular assessment includes assessing for changes in circulation, motor function, and sensation. Box 27-8 outlines the components of a neurovascular assessment.

Box 27-8 Components of a Neurovascular Assessment

- **Pain:** Extreme pain, especially on passive motion, is a significant sign of probable neurovascular impairment in an extremity. Subjective and objective assessments should be included. Opioid analgesia is unlikely to relieve the pain.
- **Pallor (perfusion):** Comparison between affected and unaffected limb is important. Assess color and temperature of the extremity. Pale skin, decreased tone, or white color may indicate poor arterial perfusion. Cyanosis may indicate venous stasis. Coolness or decreased temperature may indicate decreased arterial supply. Compare distal to proximal temperature variation in affected limb. Assess capillary refill.
- **Peripheral pulses:** Comparison between affected and unaffected limb is important. Assess the consistency of arterial blood flow (pulse presence, rate, quality) to and past the affected area. Assess capillary refill, especially in patients whose pulses cannot be palpated due to casts or bandages and in nonverbal patients.
- **Paresthesia (sensation):** May be first symptom of changes in sensory nerves to appear. Numbness, tingling, or "pins and needles" sensations may be reported. Evaluate the areas above and below the affected area.
- **Paralysis (movement):** The ability of the patient to move the extremity distal to the injury. Paralysis of an extremity may be the result of prolonged nerve compression or irreversible muscle damage.
- **Pressure:** Comparison between affected and unaffected limb is important. Swelling occurs as a physiologic response to injury. Affected area may become taut and firm to the touch, with surrounding skin appearing shiny. The feeling of tightness or pressure may be present.
- **Blood loss/ooze:** Assess blood loss on dressings, casting materials any surgical drains.

Wolters Kluwer; Johnston-Walker, E., & Hardcastle, J. (2011). Neurovascular assessment in the critically ill patient. *Nursing in Critical Care*, *16*(4), 170–177 with permission from John Wiley and Sons.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common cardiovascular and peripheral vascular variations in newborns and children include:

- Visible cardiac pulsation if the chest wall is thin
- Sinus dysrhythmia (the rate increases with inspiration and decreases with expiration)
- Presence of S_3 (in about one third of all children)
- More rapid heart rate (until about age 8 or 10 years)

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common cardiovascular and peripheral vascular variations in older adults include:

- Difficult to palpate apical pulse
- Difficult to palpate distal arteries
- More prominent and tortuous blood vessels; varicosities common
- Increased systolic and diastolic blood pressure
- Widening pulse pressure (refer to Chapter 26)

Assessing the Breasts and Axillae

Although the assessments and disorders described here focus on the female breast, men also are at risk for breast disease. Figure 27-24 provides a lateral cross section of the breast, including the underlying structures. Each breast has a lymphatic network that drains into the underlying axilla (Fig. 27-26 on page 807). Physical assessment of the breasts and axilla is primarily conducted to identify any lumps in the breasts and/or enlargement or pain in axillary lymph nodes; if

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

assessed, the patient should have further diagnostic tests.

Research does not show a clear benefit of regular physical breast exams, and as a result regular clinical breast exam and breast self-exam are not recommended (American Cancer Society, 2020; U.S. Preventive Services Task Force and the American Congress of Obstetricians and Gynecologists, as cited in Johns Hopkins Medicine, n.d.). Early detection tests, such as breast cancer screening, are based on an individual woman's risk for breast cancer and include risk assessment tools, mammograms, magnetic resonance imaging (MRI), ultrasound, and other tests. The American Cancer Society provides recommendations for early breast cancer detection. These recommendations can be accessed on the American Cancer Society's website at www.cancer.org. Women should be familiar with how their breasts normally look and feel as a result of everyday self-care and promptly report changes to a health care provider (American Cancer Society, 2020). Review information related to breast self-awareness with the patient after completion of the physical exam. Box 27-9 outlines information related to breast self-awareness.

Box 27-9 Breast Self-Awareness

All women should be familiar with how their breasts normally look and feel. This helps in noticing any changes. Instruct patients to contact a health care provider for any changes in their breasts.

Changes to look for:

- Lumps
- Change in size or shape
- Skin irritation, such as redness, thickening, dimpling of skin
- Pain or redness of a nipple
- Nipple discharge other than breast milk
- Swelling

Source: Adapted from Johns Hopkins Medicine. (n.d.). *Health. Wellness and prevention. Breast self-awareness*. https://www.hopkinsmedicine.org/health/wellness-and-prevention/breast-self-awareness; American College of Obstetricians and Gynecologists. (2017). *Mammography and other screening tests for breast problems*. *Frequently asked questions: Gynecologic problems*. https://www.acog.org/patient-resources/faqs/gynecologic-problems/mammography-and-other-screening-tests-for-breast-problems.

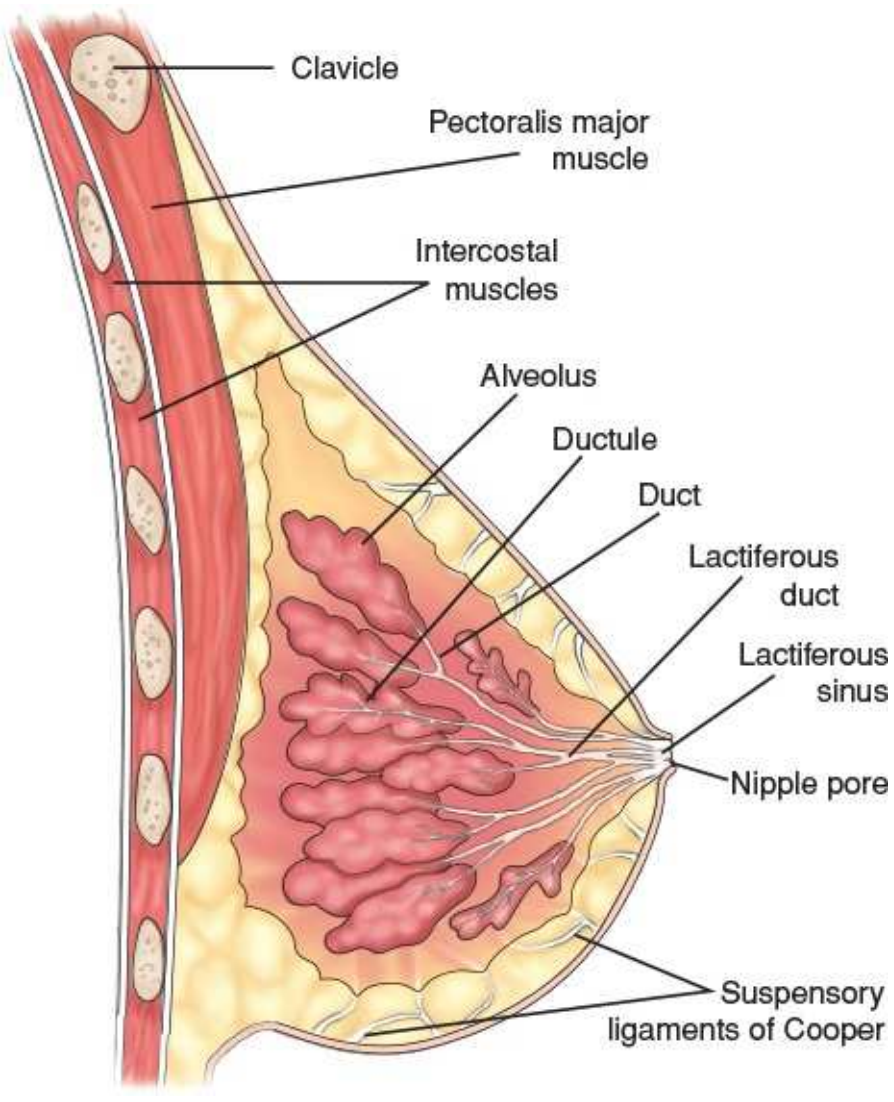


FIGURE 27-24. Lateral view of the female breast.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of pain in one or both breasts, including relationship to menstrual period
- History of lumps or swelling, redness, change in size, or dimpling in the breasts
- History of discharge from the breast
- Family history of ovarian or breast cancer

- History of breast disease, biopsy, or surgery
- Menstrual and pregnancy history, breastfeeding
- Use of hormones, oral contraceptives
- Knowledge related to breast self-awareness
- Most recent mammogram

PHYSICAL ASSESSMENT

If assessment of the breasts is required, assess the breasts and axilla in both men and women using inspection and palpation. The patient can be sitting or lying supine. When sitting, the patient should sit erect, with arms at sides or raised overhead, if possible. When supine, the patient's hand on the side being examined is placed under the head, if possible. Examination of the breast and axilla is often performed sequentially with the assessment of the thorax, lungs, and heart.

Inspecting the Breasts

Inspect the breasts for size, shape, symmetry, color, texture, and skin lesions. The breasts should be relatively symmetric, although variations are normal. The size varies among people. The shape of the breasts is round and smooth, and there should be no skin depressions (retraction) or puckering (dimpling). The color should be consistent with the rest of the skin, and the texture of the skin should be soft.

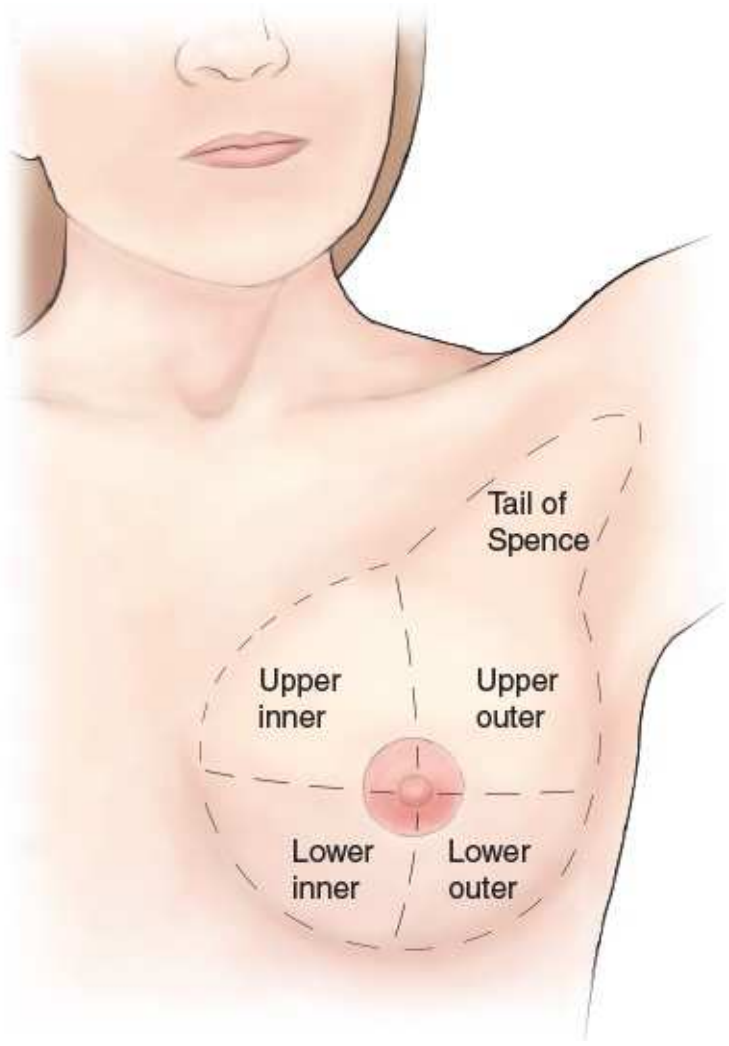

FIGURE 27-25. Location of assessment findings of the breast is identified by quadrant.

Inspect the areola and nipples for size and shape and the nipples for discharge, crusting, and inversion. The areolar and nipple areas should be equal in size, round or oval, with a smooth surface. Montgomery's tubercles (sebaceous glands on the areolae of the breasts) are a normal component of the areola. The nipples are normally everted. Discharge from the nipples is an abnormal finding except in pregnancy (leaking is normal during pregnancy and breastfeeding). Other abnormal findings include dimpling, lesions, and asymmetry.

Palpating the Breasts and Axillae

Palpate the breasts in each of the four quadrants (the upper outer quadrant, the lower outer quadrant, the upper inner quadrant, and the lower inner quadrant) to detect any abnormal lumps (Fig. 27-25). Guidelines for Nursing Care 27-4 provides instructions for palpation.

Palpate the nipple and areola, and gently compress the nipple between the thumb and forefinger to assess for discharge. The breast tissue should be smooth and firm, with a granular consistency. If a mass is detected, carefully assess its location, size, shape, consistency, and tenderness. The breasts are normally tender during the week before menstruation.

An increase in the nodularity and tenderness of the breasts may be associated with the menstrual period or may indicate fibrocystic disease. Discharge, lumps, lesions, dimpling, asymmetry, and palpable lymph nodes may be indicative of breast cancer.

Palpate the axillary areas for lymph nodes (Fig. 27-26), which normally are nonpalpable and nontender. If any nodes

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

are palpable, assess their location, size, shape, consistency, tenderness, and mobility. Palpable lymph nodes are an abnormal finding.

Guidelines for Nursing Care 27-4

Palpating the Breasts

Palpate each quadrant of each breast in a systematic method, either the circular, wedge, or vertical strip technique. The patient should be supine with a small pillow or towel beneath her back, and the arm on the side of the breast to be examined, raised above her head.

Circular

- Start at the tail of Spence and move in increasingly smaller circles (Figure A).
- Use the pads of the first three fingers to gently compress the breast tissue against the chest wall.

FIGURE A. Circular technique.

Wedge

- Work in a clockwise direction and palpate from the periphery toward the areola (Figure B).
- Use the pads of the first three fingers to gently compress the breast tissue against the chest wall.

FIGURE B. Wedge technique.

Vertical Strip

- Start at the outer edge of the breast and palpate up and down the breast (Figure C).
- Use the pads of the first three fingers to gently compress the breast tissue against the chest wall.

FIGURE C. Vertical strip technique.

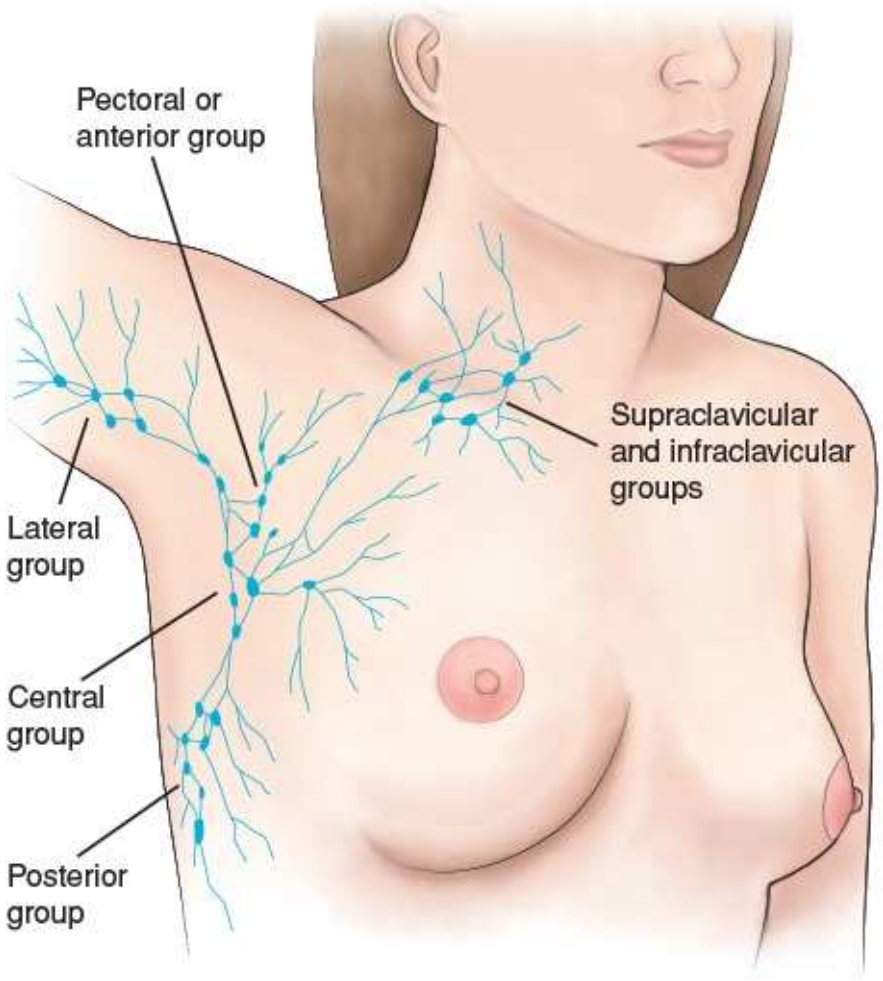

FIGURE 27-26. Location of the cervical, axillary, and mammary lymph nodes.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common breast and axillae variations in newborns and children include:

- Breast enlargement and a white discharge from the nipples (up to age 2 weeks)
- Female breast growth beginning at age 10 or 11 years
- Temporary enlargement of one or both breasts (gynecomastia) in pubescent boys

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common breast and axillae variations in older adults include granular, pendulous breasts in women.

Assessing the Abdomen

The abdominal cavity (Fig. 27-27 on page 808) contains the stomach, the small intestine, the large intestine, the liver, the gallbladder, the pancreas, the spleen, the kidneys, and the urinary bladder. The abdominal cavity also contains the female reproductive organs.

FIGURE 27-27. Organs of the abdominal cavity.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Health history questions are used to identify subjective data, including abdominal pain and nausea, and to collect data about the patient's elimination patterns, fluid and nutritional intake, and lifestyle. Physical examination is conducted to further assess problems with pain and to identify abdominal masses. Abdominal assessments are also used to assess for the presence of bowel sounds (e.g., the return of bowel sounds after surgery) and retention of urine in the urinary bladder.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- History of abdominal pain
- History of indigestion, nausea or vomiting, constipation or diarrhea
- History of food allergies or lactose intolerance
- Appetite and usual food and fluid intake
- Usual bowel and bladder elimination patterns
- History of gastrointestinal disorders
- History of urinary tract disorders
- History of abdominal surgery or trauma
- Amount and type of alcohol ingestion
- For women, menstrual history

PHYSICAL ASSESSMENT

Ask the patient to empty the bladder. Place the patient in the supine position with the head slightly elevated and arms at the sides, if possible. Place small pillows under the head and knees for comfort. Make sure that the patient is warm and comfortable to help prevent contraction of the abdominal muscles, which makes palpation difficult.

The abdomen can be divided into four quadrants: right upper, right lower, left upper, and left lower (Fig. 27-28). The sequence of techniques used to assess the abdomen is inspection, auscultation, percussion, and palpation. *Percussion and palpation are done after auscultation because they stimulate bowel sounds.* Ask the patient to breathe slowly and deeply through the mouth during the examination to promote relaxation. Ask the patient to identify painful areas of the abdomen and explain that you will assess these at the end of the examination. Advanced health care providers usually perform percussion of the abdomen, which is an advanced assessment skill. Refer to a health assessment text for details.

Inspecting the Abdomen

Inspect skin color and surface characteristics, including the umbilicus, contour, symmetry, peristalsis, pulsations, and visible masses. The skin color may be slightly lighter than exposed areas. Fine white or silver lines (striae) may be visible, often the result of skin stretching from weight gain or pregnancy; recent or new striae appear pink or bluish. The umbilicus should be centrally located and may be flat, rounded, or concave. The abdomen should be evenly rounded or symmetric, without visible peristalsis. In thin people, an upper midline pulsation may normally be visible. Abnormal findings include asymmetry (possibly from an enlarged organ or mass), distention (possibly indicating retained gas or air; obesity), swelling of the abdomen (possibly indicating fluid retention called ascites), and abdominal masses or unusual pulsations.

Auscultating Bowel Sounds and Vascular Sounds

Auscultation is used to assess bowel sounds and vascular sounds. Warm the stethoscope. Traditionally, bowel sounds are assessed in all four quadrants of the abdomen. Using light pressure, place the flat diaphragm on the right lower quadrant of the abdomen, then move to right upper quadrant, left upper quadrant, and finally to the left lower quadrant. Listen carefully for bowel sounds (gurgles and clicks), and note their frequency and character (usually occur every 5 to 15 seconds). Before documenting bowel sounds as absent, the nurse must listen for 1 minute or longer in each abdominal quadrant (Jensen, 2019; Weber & Kelley, 2018). Some sources suggest bowel sounds radiate widely over the abdomen, and listening in all four quadrants is not necessary; assessment of presence and hypoactivity (decreased)/hyperactivity (increased) is sufficient (Jarvis & Eckhardt, 2020; McGee, 2018). Abnormal findings include increased bowel sounds (often heard with diarrhea or in early bowel obstruction), decreased bowel sounds (heard after abdominal surgery or late bowel obstruction), or absent bowel sounds (indicating peritonitis or paralytic ileus). Bowel sounds of high-pitched tinkling or rushes of high-pitched sounds indicate a partial bowel obstruction.

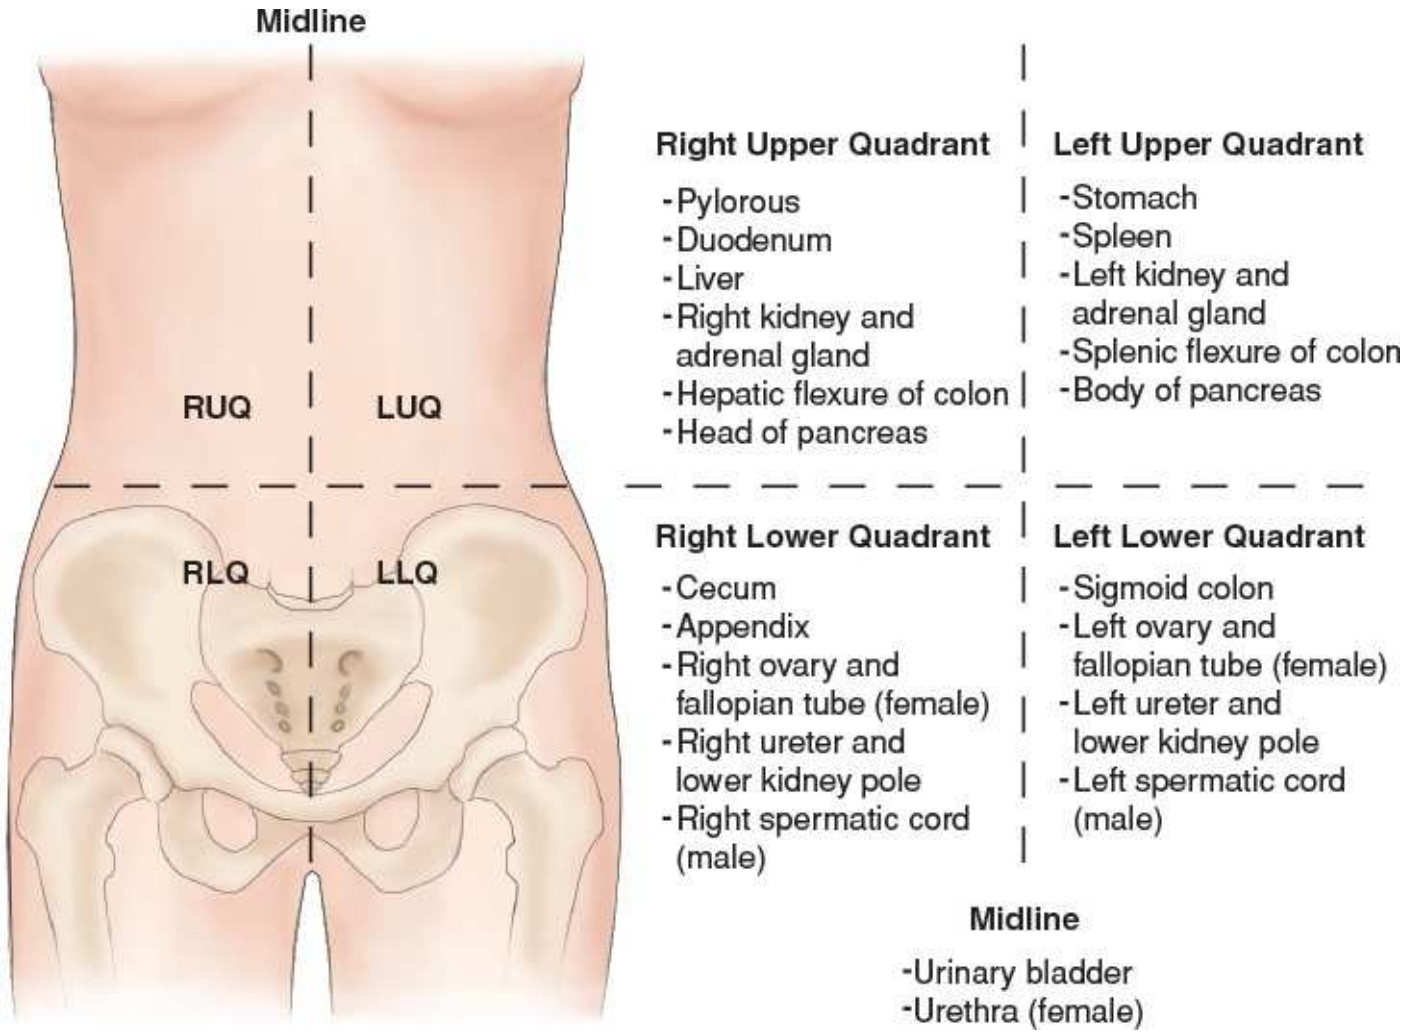

FIGURE 27-28. Diagram of abdominal quadrants and outline of underlying organs.

Using the bell of the stethoscope, auscultate over the abdominal aorta, femoral arteries, and iliac arteries for bruits. Bruits are abnormal "swooshing or blowing" sounds heard over a blood vessel, caused by blood that is swirling in the vessel, rather than normal smooth flow. A bruit may be heard in the presence of stenosis (narrowing) or occlusion of an artery. Bruits may also be caused by abnormal dilation of a vessel. Report and document changes in or absence of bowel and vascular sounds.

Palpating the Abdomen

Use light palpation to assess the abdomen; apply pressure with the fingers together and lightly depressing the skin and underlying structures about 1 to 2 cm (0.5 to 0.75 inch) (Jarvis & Eckhardt, 2020; Jensen, 2019; Weber & Kelley, 2018). Watch the patient's face for nonverbal signs of pain during palpation. Palpate each quadrant in a systematic manner, noting muscular resistance, tenderness, or masses. If the patient reports abdominal pain, palpate the area of pain last. The abdomen should normally be soft, relaxed, and free of tenderness. Abnormal findings include involuntary rigidity, spasm, masses, and pain (which may indicate trauma, peritonitis, infection, tumors, or enlarged or diseased abdominal organs).

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common abdominal variations in newborns and children include:

- Umbilical cord in newborns; dries and falls off within the first few weeks of life
- A "potbelly" (younger than age 5 years)
- Visible peristaltic waves

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common abdominal variations in older adults include:

- Decreased bowel sounds
- Decreased abdominal tone
- Fat accumulation on the abdomen and hips

Assessing Female Genitalia

The external female genitalia consist of the mons pubis, labia majora and minora, clitoris, vestibular glands, vaginal vestibule, vaginal orifice, and urethral opening (Fig. 27-29 on page 810). Information collected during the health history is especially helpful in identifying risk factors for cancer and health-related behaviors that increased risk for sexually transmitted infections. During the physical assessment, the external genitalia may be examined. The female genitalia are assessed for lesions, discharge, masses, and enlargement of internal organs. The rectum and anus may be assessed during part of this examination if a complete health assessment is being performed. Information about rectal examination is provided later in this chapter. The internal pelvic examination is an advanced skill, usually performed by an advanced practice professional. Refer to a health assessment text for details of this advanced assessment skill.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

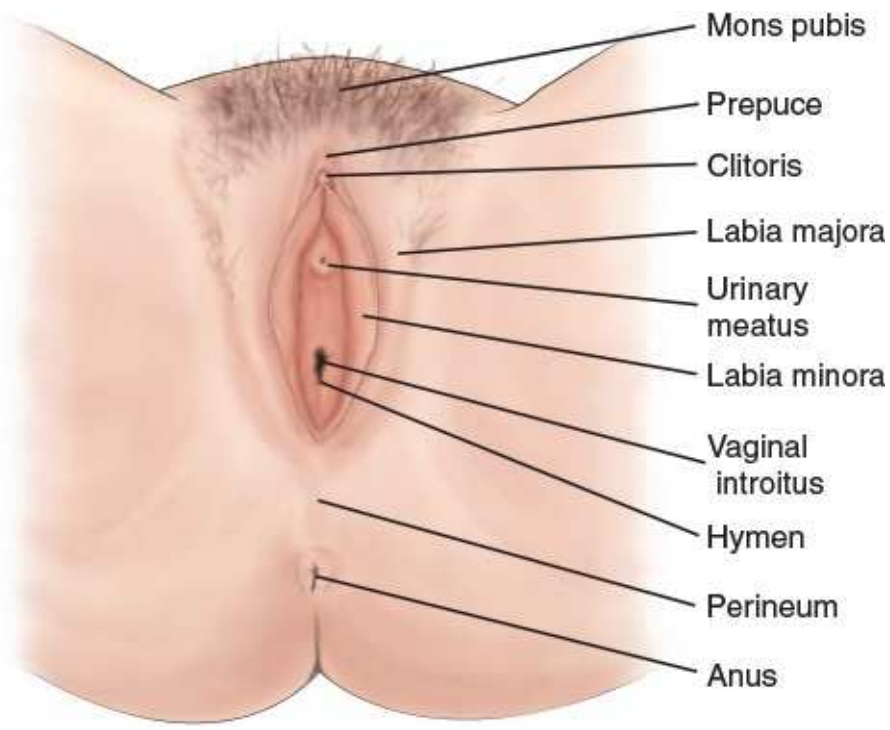

FIGURE 27-29. External female genitalia.

HEALTH HISTORY

Identify risk factors for altered female health during the health history by asking about the following:

- Menstrual history (age of first and last period, length of flow, type of flow, pain)
- Sexual history (age at which sexual activity began, number and biologic sex of partners, practices)
- Pain with intercourse, difficulty achieving orgasm
- Number of pregnancies and live births
- History of sexually transmitted infection
- Use of contraceptives/protection from sexually transmitted infections (STIs)
- Frequency of pelvic examinations and Pap smears
- History of vaginal discharge, itching, or pain on urination
- Use of hormones and tobacco (how long, how much, how many packs/day)

PHYSICAL ASSESSMENT

Assess the genitalia by inspection and palpation. A description of an internal pelvic assessment of women is included in this chapter. This is an advanced assessment technique, but nurses often assist in performing vaginal examinations and need to be familiar with the procedure. In many instances, male health care providers will ask that a female be present in the room during the examination. Women from some cultures or who practice certain religions may agree to a physical examination of the genitalia only by a female nurse or female health care provider. Equipment required includes a good light source and disposable gloves.

Inspecting and Palpating the External Genitalia

Ask the patient to empty her bladder before the examination. Explain the procedure to her and help her to relax as it is performed. The patient should be supine or lying on her side.

Inspect the external genitalia for color, size of the labia majora and vaginal opening, lesions, and discharge. The vulva normally has more pigmentation than other skin areas, and the mucous membranes are dark pink and moist. The skin and mucosa should be smooth, without lesions or swelling. The labia should be symmetric without lesions or swelling. Lesions may be the result of infections (such as herpes or syphilis). There may normally be a small amount of clear or whitish vaginal discharge. The vaginal orifice varies in size, depending on the woman's age, sexual history, and having vaginal delivery. In children, loss of hymenal tissue between the 3 o'clock and 9 o'clock position indicates trauma (from digits, penis, or foreign objects). Palpate the labia for masses.

Abnormal findings include redness, swelling, discharge, lesions, and pain, which may indicate infection, an abscess, or cancer. For related assessments of the urinary tract and sexually transmitted infections, see Chapters 38 and 46.

Inspecting Internal Genitalia

Examination of the internal genitalia is an advanced assessment technique and usually performed by advanced health care providers. The examination is outlined here to provide the student with an understanding of the examination if asked to assist. The patient is placed in the lithotomy position on the examination table, with the legs in stirrups, and draped so that only the genitalia are exposed. Explain the procedure and help the patient to relax as it is performed. A speculum, consisting of two blades and an adjustment device, is lubricated and inserted into the vagina. This allows inspection of the cervix and other internal genitalia for abnormalities. Specimens for a Papanicolaou (Pap) test for cervical and vaginal cancer can be obtained, as well as specimens for gonorrhea and chlamydia cultures, and to test for human papillomavirus (HPV). The vaginal wall is inspected as the speculum is removed. With lubricated fingers, the advanced practice professional palpates the internal genitalia for location, size, mobility, tenderness, and masses. Refer to a health assessment text for additional details of this advanced assessment skill. The examination of the rectum is

often included at this time. This examination is discussed later in the chapter.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common genitalia variations in newborns (resulting from exposure to maternal hormones in utero, normally seen in the first week after birth and subsiding by the second week after birth) and children include:

- Enlarged labia and clitoris
- Breast enlargement
- Vaginal discharge in girls, called pseudomenstruation
- Pubic hair and breast development occur at puberty and follow a regular sequence of development
- Menstruation begins about 2.5 years after puberty begins
- Irregular menstrual cycle for first 2 years

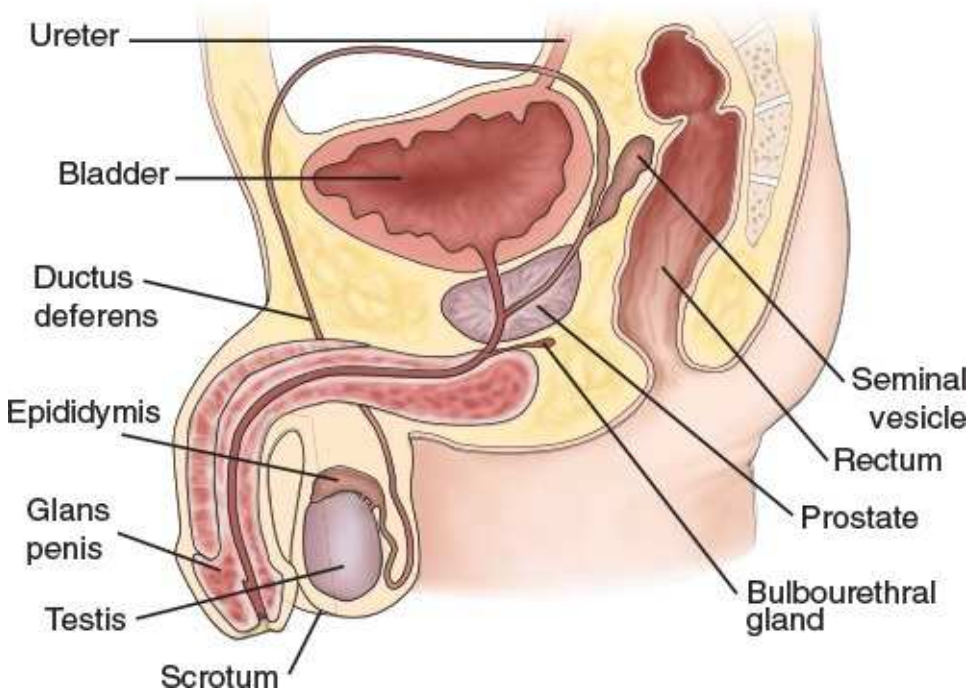

FIGURE 27-30. Organs of the male genital system.

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common genitalia variations in older women include:

- Decreased size of labia and clitoris
- Decreased amount of pubic hair
- Decreased vaginal secretions
- Pale, thin, and dry vaginal mucosa

Assessing Male Genitalia

The male genitalia (Fig. 27-30) include the penis, testicles, epididymis, scrotum, prostate gland, and seminal vesicles. In addition, the inguinal area may be examined as part of this assessment. Information from the health history is helpful in identifying self-care and lifestyle factors that increase the risk of illnesses, such as testicular cancer or sexually transmitted infections. The physical examination is focused on detecting abnormal findings so that early identification and treatment can be initiated. Review or teach the procedure for testicular self-examination after completion of the physical exam. Figure 27-31 reviews the procedure for testicular self-examination.

HEALTH HISTORY

Identify risk factors for altered male health during the health history by asking about the following:

- Frequency of digital rectal examinations (DREs)
- Frequency of testicular self-examination
- Use of contraceptives/protection from sexually transmitted infections (STIs)
- Occupational exposure to chemicals (tire and rubber manufacturing, farming, mechanics)
- Sexual history (age at which sexual activity began, number and biologic sex of partners, practices)
- History of sexually transmitted infection
- History of discharge from the penis
- Difficulty with urination (incontinence, hesitancy, frequency, voiding at night)
- History of erectile dysfunction, pain with intercourse

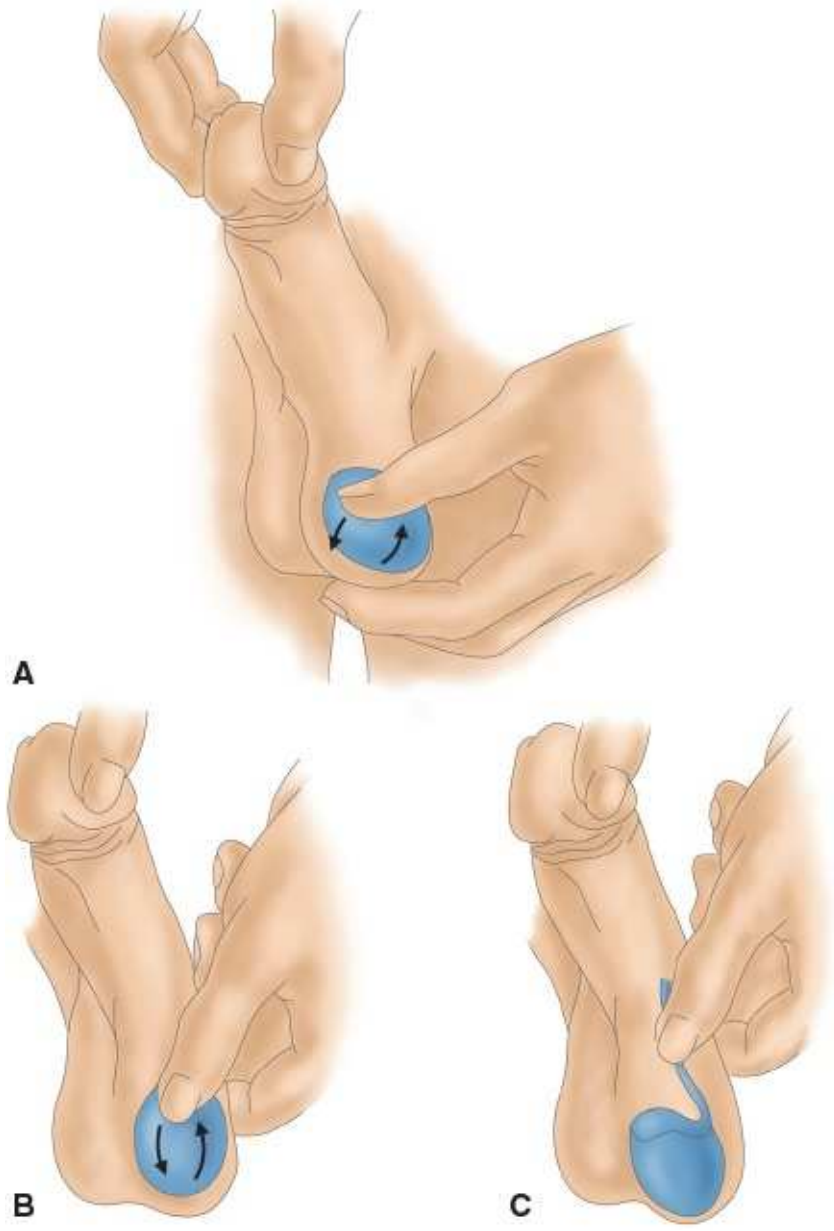

FIGURE 27-31. Testicular self-examination. A convenient time is after a warm bath or shower when the scrotum is relaxed. Both hands are used to palpate the testis; the normal testicle is smooth and uniform in consistency. **A.** With the index and middle finger under the testis and the thumb on tip, roll the testis gently in a horizontal plane between the thumb and fingers, feeling for any evidence of a small lump or abnormality. **B.** Follow the same procedure for palpation in a vertical plane. **C.** Locate the epididymis (small, coiled tube) on the top and back of the testicle that may feel like a small bump. Repeat the examination for the other testis; it is normal to find one testis larger than the other. Any changes should be reported to a health care provider. [2018]. *Testicular exam*. https://www.mayoclinic.org/tests-procedures/testicular-exam/about/pac-20385252.)

PHYSICAL ASSESSMENT

The patient may be standing or supine. Gloves are worn during this assessment.

Inspecting and Palpating the External Genitalia

The external genitalia are inspected for size, placement, contour, appearance of the skin, redness, edema, and discharge. If the patient is uncircumcised, retract the foreskin for inspection of the glans penis and return foreskin back over the glans penis after inspection. Assess the location of the urinary meatus. Inspect the scrotum for symmetry; it is not unusual for the left testicle to lie lower in the scrotal sac than the right testicle. Palpate the testes. The size, shape, and consistency of the scrotal contents (i.e., testes) should be similar bilaterally. Normal findings include skin that is free of lesions, and a foreskin (if present) that is intact, uniform in color, and easily retracted. The urinary meatus is normally located in the center of the glans penis and is free of discharge. The scrotum and testes should be free of masses and nontender.

Abnormal findings include lesions, redness, edema, pain, discharge, fluid-filled masses in the scrotum (symptoms of a hydrocele or varicocele), and displacement of the urinary meatus or difficulties with voiding. Edema, redness, discharge, or pain may indicate an infection. Voiding difficulties may result from scarring caused by infections or prostate enlargement. Refer to Chapters 38 and 46 for additional discussion of the male urinary tract and sexually transmitted infections.

Inspecting and Palpating the Inguinal Area

The inguinal area may be inspected at this time by asking the patient to bear down. Normally, the inguinal area is free of bulges. Further assessment for inguinal hernia, inguinal lymph nodes, and femoral hernia is usually performed by an advanced practice professional. Refer to a health assessment text for details.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Common genitalia variations in newborns (resulting from exposure to maternal hormones in utero, normally seen in the first week after birth and subsiding by the second week after birth) and children include:

- Breast enlargement
- Development of pubic hair and enlargement of the scrotum, testes, and penis occurs at puberty and follows a regular sequence to adult configuration
- Spontaneous nocturnal emission of seminal fluid occurs at puberty

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common genitalia variations in older adults include:

- Decreased penis size
- Decreased pubic hair
- Decreased size and firmness of testes

Assessing the Rectum and Anus

Although the rectum and anus are not assessed in all patients, this assessment is a part of a total health assessment for both men and women. Assessments of the rectum and anus are usually performed by advanced practice professionals. Information from the health history provides information about normal patterns of bowel elimination and identifies risks for illness (such as colon cancer) and health behaviors (such as frequency of DREs to assess for cancer or engaging in anal intercourse). Physical examination provides information to support teaching about risk for colon cancer and the risks of sexually transmitted infections (including AIDS) associated with unprotected anal sex.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

- Bowel patterns, including constipation, diarrhea, or pain
- History of blood or mucus in the stool
- Family history of polyps, colon or rectal cancer, or prostate cancer
- History of hemorrhoids
- Frequency of DREs
- History of anal intercourse

PHYSICAL ASSESSMENT

Techniques used to assess the rectum and anus include inspection and palpation. Gloves and good lighting are necessary equipment. The patient may be in the knee–chest or side-lying position.

Inspection is used to assess the anal area, which normally has increased pigmentation and some hair growth. Assess for lesions, ulcers, fissures, inflammation, and external hemorrhoids (dilated veins appearing as reddened protrusions). Ask the patient to bear down as though having a bowel movement. Assess for the appearance of internal hemorrhoids or fissures. Normally, there is no protrusion of tissue. Abnormal findings include relaxed sphincter tone; skin cracks, nodules, or hemorrhoids at the anal sphincter; and bleeding (which may indicate hemorrhoids or colorectal cancer). Advanced practice professionals usually perform palpation of the anal canal and sphincter and the prostate gland in men. Refer to a health assessment text for details.

NORMAL AGE-RELATED VARIATIONS: INFANT/CHILD

Normally physical examination of the rectum and anus is not performed in young children or adolescents.

NORMAL AGE-RELATED VARIATIONS: OLDER ADULT

Common variations in older adults include:

- Anus is darker in color
- Hemorrhoids

Assessing the Musculoskeletal System

The primary structures of the musculoskeletal system are the bones, muscles, cartilage, ligaments, tendons, and joints. Health history information is used to evaluate the patient's ability to carry out ADLs and to collect data about areas such as pain, stiffness, and ability to move. Physical examination provides information about posture, gait, bone size and structure, joint range of motion (ROM; the maximum degree of movement of which a joint is normal capable), and muscle strength. Normally, the joints are bilaterally equal in size, shape, and color; are free of swelling, pain, nodules, or crepitus (grating sounds on movement); and can move through full ROM. Abnormal findings include deformity, crepitus, and limited ROM (indicating injury, inflammation and/or arthritis of the affected joints or bones, and muscle pain and/or weakness caused by injury or disease). *Many health care providers assess the neuromuscular, musculoskeletal, and peripheral vascular systems as an integrated assessment.* Refer to Skill 27-2 (on pp. 824–830) for an example of a systematic, integrated assessment of these systems.

HEALTH HISTORY

Identify risk factors for altered health during the health history by asking about the following:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- History of trauma, arthritis, or neurologic disorder
- History of pain or swelling in the muscles and/or joints
- Frequency and type of usual exercise
- Dietary intake of calcium
- History of any surgery on muscles or joints
- History of smoking (how long, how many packs/day)
- History of alcohol intake

PHYSICAL ASSESSMENT

Assess the patient's ability to assume a variety of positions, including standing, sitting, and supine, if possible. *Assessments of the musculoskeletal system can be integrated into assessment of other body systems.*

Inspecting and Palpating the Muscles

Examine the muscles by inspection and palpation of muscle groups and by testing muscle tone and strength. Muscle groups are observed for bilateral symmetry and palpated for tenderness. Normally, they are symmetric and nontender. Evaluate muscle tone (the normal condition of a muscle at rest) by putting each joint and extremity through passive ROM. Assess muscle strength. Guidelines for Nursing Care 27-5 (on pages 814–815) describes testing muscle strength.

Abnormal findings include atrophy (a decrease in size), tremors (involuntary movements), and flaccidity (without tone) of muscles. Other abnormal findings are loss of strength and tone, decreased ROM, uncoordinated movements, swelling, and pain. Abnormal findings may indicate a musculoskeletal disease, trauma, or a neurologic disease.

Palpating the Bones

Palpate the bones for normal contour and prominence and for bilateral symmetry. Abnormal findings include pain, enlargement, asymmetry, and changes in contour. Abnormal findings may indicate trauma, degenerative joint disease, musculoskeletal disease, or a neurologic disease.

Inspecting and Palpating the Joints

Each joint is put through its full ROM to assess the degree of movement. Joint movements include flexion, extension, hyperextension, abduction, adduction, supination, and pronation. Normally, each joint has full ROM, is nontender, and moves smoothly. Palpate joints for the abnormal findings of pain, swelling, nodules, and crepitation (a grating sound heard or felt on movement).

Inspecting Spinal Curves

With the patient standing, inspect the spine from the back and from the side. The spine normally has concave curves at the cervical and lumbar spine and convex curves at the thoracic and sacrococcygeal spine. Kyphosis (an increased thoracic spinal curve) is more often seen in older adults. An exaggerated lumbar curve (lordosis) is often seen during pregnancy or in obesity. Scoliosis is a lateral curvature of the spine with increased convexity on the side that is curved. School nurses often first identify scoliosis during screenings, which are recommended twice for girls at ages 10 and 12, and once for boys at ages 13 to 14 years (Hresko et al., 2015). Findings indicating scoliosis are illustrated in Figure 27-32.

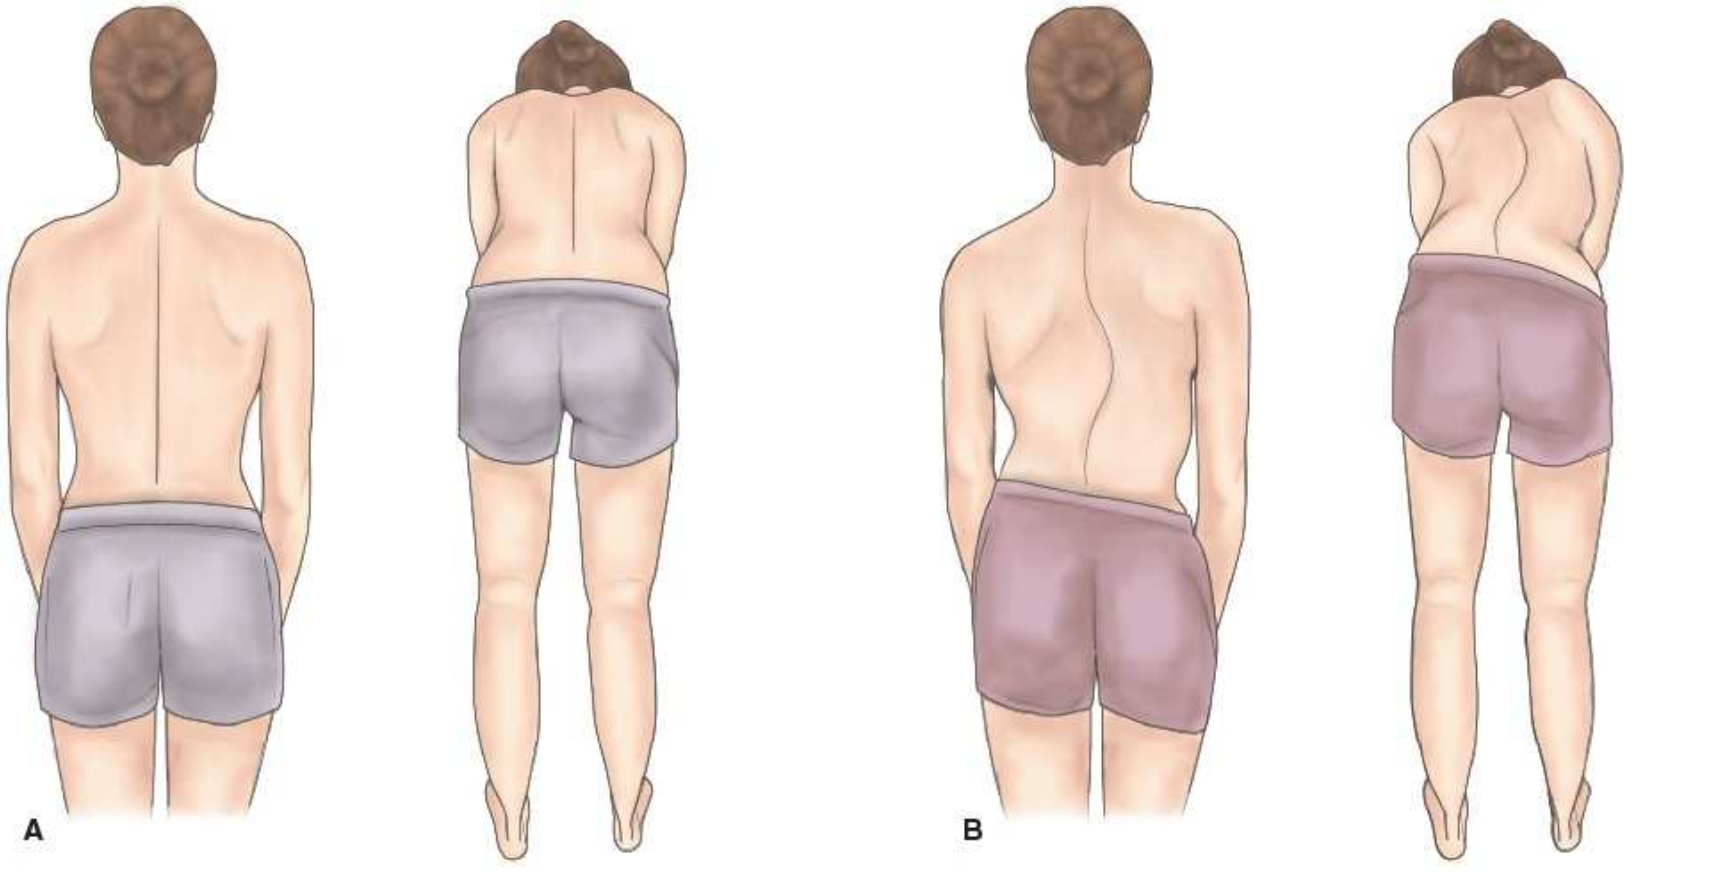

FIGURE 27-32. Screening for scoliosis. **A.** Normal position and spinal curves. **B.** Scoliosis indicators.

Guidelines for Nursing Care 27-5

Assessing Muscle Strength

Assess muscle strength by asking the patient to move against resistance. Bilateral equal resistance should be present. Observe muscle contraction and determine muscle strength exerted. Muscle strength should be bilaterally equal, with a slight increase on the dominant side. Techniques for assessing the muscles include:

Shoulder Flexion

The patient flexes shoulder muscle against resistance of the examiner's hand (Figure A).
